Background - Public and private agencies are cooperating in a study of eight thinning regimes in young Douglas-fir stands. Regimes differ in the amount of basal area allowed to accrue in growing stock at each successive thinning. All regimes started with a common level of growing stock established by a calibration thinning.

Thinning interval is controlled by the height growth of crop trees, and a single type of thinning is prescribed.

Nine study areas, each involving three completely random replications of each thinning regime and an unthinned control, have been established in western Oregon and Washington, USA, and on Vancouver Island, British Columbia, Canada. Site quality of these areas varies from I to IV.

This is a progress report on this cooperative study.

In 1969, the Canadian Forest Service (CFS) joined the Levels-Of-GrowingStock (LOGS) cooperative study in Douglas-fir, coordinated by the Pacific Northwest Research Station, U.S. Forest Service, Portland, Oregon. While following the cooperative study publication format, the CFS is publishing its own reports on work done under the LOGS program. Thus, this report is both Report No. 16 in the LOGS series and CFS Information Report BC-X-393.

#### Abstract

Results from the two levels-of-growing-stock installations at Sayward Forest and Shawnigan Lake on Vancouver Island, British Columbia, Canada, are summarized. Volume growth at both the site-III Sayward Forest installation to age 51 and the site-IV Shawnigan Lake installation to age 52 has been strongly related to level of growing stock. Basal area growth followed a similar, though weaker, trend. Thinning has affected stand development through tree size distribution and live crown development. Periodic annual increments in volume at both installations are still two to three times the mean annual increment, indicating the potential for productivity gains as the treated stands age. Results to date from both installations are similar to results from other cooperative installations, generally differing from the more productive sites only in the rate and degree of response associated with a lower site quality.

## Résumé

Les résultats de la recherche sur la densité du matériel sur pied aux installations de la forêt Sayward et de Shawnigan Lake dans lîle de Vancouver (Colombie-Britannique) au Canada sont résumés. Une relation étroite a été mise en évidence entre la densité et l'accroissement du volume jusqu'à 51 ans au site de la forêt Sayward (classe III) et jusqu'à 52 ans à celui de Shawnigan Lake (classe IV). Une tendance similaire, mais plus faible, a été observée pour l'accroissement de la surface terrière. L'éclaircie a influé sur le développement des peuplements en modifiant la distribution de la taille des arbres et en stimulant le développement du houppier. L'accroissement annuel périodique du volume aux deux installations est encore de deux à trois fois supérieur à l'accroissement annuel moyen, indiquant des gains potentiels de productivité avec le vieillissement des peuplements traités. Les résultats des deux installations jusqu'à maintenant sont similaires à ceux d'autres installations du projet conjoint, différant généralement des sites plus productifs seulement par la vitesse et l'intensité de la réaction des arbres, correspondant à la qualité inférieure des sites.

## Other LOGS (Levels-Of-Growing-Stock) Reports

Williamson, Richard L.; Staebler, George R. 1965. A cooperative levels-of-growing-stock study in Douglas-fir. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station. Portland, OR. 12 p.

Describes purpose and scope of a cooperative study investigating the relative merits of eight different thinning regimes. Main features of six study areas installed since 1961 in young stands also are summarized.

Williamson, Richard L.; Staebler, George R. 1971. Levels-of-growing-stock cooperative study on Douglas-fir: report no. 1- description of study and existing study areas. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR. Research Paper PNW-111. 12 p.

Thinning regimes in young Douglas-fir stands are described. Some characteristics of individual stands areas established by cooperating public and private agencies are discussed.

Bell, John F.; Berg, Alan B. 1972. Levels-of-growing-stock cooperative study on Douglas-fir: report no. 2 the Hoskins study, 1963-70. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR. Research Paper PNW-130. 19 p.

A calibration thinning and the first treatment thinning in a 20-year-old Douglas-fir stand at Hoskins, Oregon, are described. Growth for the first 7 years after thinning was greater than expected.

Diggle, P.K. 1972. The levels-of-growing-stock cooperative study in Douglas-fir in British Columbia (report no. 3, cooperative L.O.G.S. study series). Canadian Forestry Service, Pacific Forest Research Centre, Victoria, BC. Information Report BC-X-66. 46 p.

Describes the establishment and installation of the two LOGS studies established on Vancouver Island at Shawnigan Lake and Sayward Forest.

Williamson, Richard L. 1976. Levels-of-growing-stock cooperative study in Douglas-fir: report no. 4 —-Rocky Brook, Stampede Creek, and Iron Creek. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR. Research Paper PNW-210. 39 p.

The USDA Forest Service maintains three of nine installations in a regional cooperative study of influences of levels of growing stock (LOGS) on stand growth. The effects of calibration thinnings are described for the three areas. Results of first treatment thinning are described for one area.

Berg, Alan B.; Bell, John F. 1979. Levels-of-growing-stock cooperative study on Douglas-fir: report no. 5 - the Hoskins study, 1963-75. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR. Research Paper PNW-257. 29 p.

Growth data are presented for the first 12 years of management of young Douglas-fir growing at eight levels of growing stock. The second and third periods are described.

Young Douglas-fir stands transfer growth from many to few trees. Some of the treatments have the potential to equal the gross cubic-foot volume of the controls during the next treatment periods.

Arnott, J.T.; Beddows, D. 1981. Levels-of-growing-stock cooperative study in Douglas-fir: report no. 6 - Sayward Forest, Shawnigan Lake. Environment Canada, Canadian Forestry Service, Pacific Forest Research Centre, Victoria, BC. Information Report BC-X-223. 54 p.

Data are presented for the first 8 and 6 years at Sayward Forest and Shawnigan Lake, respectively. The effects of the calibration thinning are described for these two installations on Vancouver Island, British Columbia. Results of the first treatment thinning at Sayward Forest for a 4 -year response period are also included.

Williamson, Richard L.; Curtis, Robert O. 1994. Levels-of-growing-stock cooperative study in Douglas-fir: report no. 7 Preliminary results; Stampede Creek, and some comparisons with Iron Creek and Hoskins. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR. Research Paper PNW323.42 p.

Results of the Stampede Creek LOGS study in southwest Oregon are summarized through the first treatment period, and results compared with two more-advanced LOGS studies and are generally similar.

Curtis, Robert O.; Marshall, David D. 1986. Levels-of-growing-stock cooperative study in Douglas-fir: report no. 8 - the LOGS study: twenty-year results. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR.. Research Paper PNW-356. 113 p.

Reviews history and status of LOGS study and provides new analyses of data, primarily from the site II installations. Growth is strongly related to growing stock. Thinning treatments have produced marked differences in volume distribution by tree size. At the fourth treatment period, current annual increment is still about double mean annual increment. Differences among treatments are increasing rapidly. There are considerable differences in productivity among installations, beyond those accounted for by site differences. The LOGS study is evaluated.

Curtis, Robert O. 1987. Levels-of-growing-stock cooperative study in Douglas-fir: report no. 9 - some comparisons of DFSIM estimates with growth in the levels-of-growing-stock study. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR.. Research Paper PNW-376. 34 p.

Initial stand statistics for the LOGS study installations were projected by the DFSIM simulation program over the available periods of observation. Estimates were compared with observed volume and basal area growth, diameter change, and mortality. Overall agreement was reasonably good, although results indicate some biases and a need for revisions in the DFSIM program.

Marshall, David D.; Bell, John F.; Tappeiner, John C. 1992. Levels-of-growing-stock cooperative study in Douglas-fir: report no. 10 - the Hoskins study, 1963-83. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR. Research Paper PNW-448. 65 p.

Results of the Hoskins study are summarized through the fifth and final planned treatment period. To age 40, thinnings in this low site-I stand resulted in large increases in diameter growth with reductions in basal area and cubic foot volume growth and yield. Growth was strongly related to level of growing stock. All treatments are still far from culmination of mean annual increment in cubic feet.

Curtis, Robert O. 1992. Levels-of-growing-stock cooperative study in Douglas-fir: report no. 11

- Stampede Creek: a 20-year progress report. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR. Research Paper PNW-442. 47 p.

Results of the first 20 years of the Stampede Creek study in southwest Oregon are summarized. To age 53, growth in this site III Douglas-fir stand has been strongly related to level of growing stock. Marked differences in volume distribution by tree sizes are developing as a result of thinning. Periodic annual increment is about twice mean annual increment in all treatments, indicating that the stand is still far from culmination.

Curtis, Robert O.; Clendenen, Gary W. 1994. Levels-of-growing-stock cooperative study in Douglas-fir: report no. 12 - the Iron Creek study: 1966-89. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR. Research Paper PNW-475. 67 p.

Results of the Iron Creek study in the Gifford Pinchot National Forest, southern Washington, are summarized through age 42 (completion of the 60 feet of height growth comprising the planned course of the experiment). Volume growth of this mid-site II plantation has been strongly related to growing stock; basal area growth much less so. Different growing stock levels have produced marked differences in the size distribution and in crown dimension. Periodic annual volume increment at age 42 is two to three times mean annual increment in all treatments.

Hoyer, Gerald E.; Andersen, Norman A,; Marshall, David. 1996. Levels-of-growing-stock cooperative study in Douglas-fir: report no. 13 - the Francis Study: 1963-90. USDA Forest Service, Pacific Northwest Forest and Range Experiment Station, Portland, OR. Research Paper PNW-488. 91 p.

Results of the Francis installation are summarized together with results from additional first-thinning treatments started at age 25. Total volume growth on this mid-site-II Douglas-fir plantation has been strongly related to level of growing stock. Growth of lower levels of growing stock exceeded that of the control for only a brief period at age 30. Selection of a "best" treatment would depend on the unit of measure used: yield in total cubicfoot volume, merchantable cubic-foot volume, board-foot volume or dollar value. Close dollar values among several alternatives suggest that diverse stand structure objectives can be attained at age 42 with little difference in wood product value per acre. General silvicultural prescriptions could be written to achieve the results of any of the treatments on similar sites.

## Introduction

The Levels-Of-Growing-Stock (LOGS) Cooperative was established to examine the effects of different levels of growing stock on cumulative wood production, tree size development, and ratios of growth to growing stock in young Douglas-fir [Pseudotsuga menziesii (Mirb.) Franco] stands in the Pacific Northwest. The Cooperative, comprised of the USDA Forest Service, Washington State Department of Natural Resources, Weyerhaeuser Corp, Oregon State University, the British Columbia Ministry of Forests (BCMOF), and the Canadian Forest Service (CFS), was formed in the early 1960s and is coordinated by the Pacific Northwest Research Station of the USDA Forest Service at Portland, Oregon.

From 1961 to 1970, nine installations were established in young Douglas-fir stands in Oregon, Washington and British Columbia (B.C.), representing site classes II, III, and IV (King 1966). Each installation was established according to a comprehensive study plan developed to ensure standardized procedures among cooperators and comparability of results (Williamson and Staebler 1971). Detailed progress reports on individual installations are contained in the series of LOGS publications listed at the beginning of this report.

The two CFS/BCMOF installations, Sayward Forest and Shawnigan Lake, were the last of the nine to be established, and because of their lower site productivity these sites have been slower in their response than those highsite installations established earlier. Sayward Forest has completed the full schedule of treatments and Shawnigan Lake is in its fourth treatment period. Both have advanced enough to expect differences between treatments and to show possible differences in response from stands on better sites. An establishment report (Diggle 1972) and a progress report (Arnott and Beddows 1981) detailed the calibration data and some early results.

This report is one of a series of reports on individual LOGS installations and therefore follows an established format in order to easily compare results among reports. As well, during the decade when the nine installations were being established, English measure was the common measurement system in both countries. Canada converted to metric measure in the 1970s. Again, for purposes of comparability of results with previous reports, results from these two installations will be given in metric and English measure.

## Objectives

The objective of the LOGS study plan was to determine how the amount of growing stock retained in repeatedly thinned stands of Douglas-fir affects cumulative wood production, tree size, and growth-growing stock ratios. The treatment regimes were designed to cover a broad range in growing stock levels in order to produce any combination of factors deemed optimum from a management standpoint. The treatments were not specific operational thinning regimes, but were intended to examine the relationship between growth and growing stock.

## Methods

## Description of the study areas

## Sayward Forest

The Sayward Forest installation is on provincial Crown land located in the Sayward Forest 24 km ( 15 miles) west of Campbell River, B.C. (Figure 1). The installation was established in the autumn of 1969 in a plantation planted in the spring of 1950 with 2 -year-old Douglas-fir seedlings. The site was evaluated as a site index of 111 feet ( 34 m ) at age 50 (King 1966). Initial stand density was approximately 2471 stems/ha ( 1000 stems per acre) and had a minor natural fill-in component of western hemlock [Tsuga heterophylla (Raf.) Sarg.], western redcedar (Thuja plicata Donn ex D. Don), western white pine (Pinus monticola Dougl. ex D. Don) and lodgepole pine (Pinus contorta Dougl. ex Loud. var. latifolia Engelm.) (Diggle 1972).

The stand, situated at about 274 m ( 900 feet) above sea level, is on a gently rolling slope with a westerly aspect. The soil is a well-drained young podzol developed on a sandy, gravelly glacial till and is classified as a mini humoferric podzol (Canada Department of Agriculture 1970). Local average annual precipitation is 1494 mm ( 58.8 inches) per year, with 254 mm ( 10 inches) falling during the 149-day frost-free period. Temperatures are mild with an average growing season temperature of $14.7^{\circ} \mathrm{C}\left(58.4^{\circ} \mathrm{F}\right)$. Ground vegetation was predominately salal with lesser amounts of Oregon grape, braken fern, red huckleberry and willow.

As outlined in the LOGS study plan, the installation consists of twenty-seven 0.081 -ha ( $1 / 5$ acre) square plots; both Canadian installations have 10.1-m-wide (33-foot-wide) treated plot buffer surrounds (Figure 2). At establishment, the site was inspected for the occurrence of the root rot fungi Armillaria mellea and Poria Weirii. Two loci were located, plots were relocated to avoid them, and the infected trees were felled and their stumps pulled.

Figure 1. Location of the Sayward Forest and Shawnigan Lake levels-of-growing-stock study installations.

## Shawnigan Lake

The Shawnigan Lake installation is located on provincial Crown land 8.0 km ( 5 miles) west of Shawnigan Lake, B.C. (Figure 1). The installation was established in the autumn of 1970 in a plantation planted in the spring of 1948 with 2-year-old Douglas-fir seedlings. The site was evaluated as a site index of 94 feet ( 29 m ) at age 50 (King 1966). Initial stand density was approximately 2965 stems/ha ( 1200 stems/acre) and had a minor natural fill-in component of western hemlock, western redcedar, western white pine and lodgepole pine (Diggle 1972).

The plantation is situated on a flat to gently rolling low ridge 335 m ( 1100 feet) above sea level, with an easterly aspect. The soil is a sandy loam developed from underlying glacial till and is classified as a mini humo-ferric podzol (Canada Department of Agriculture 1970).

Local average annual precipitation is 1174 mm ( 46.2 inches) per year, with 178 mm ( 7 inches) falling during the 149-day frost-free period. Temperatures are mild with an average growing season temperature of $15.6^{\circ} \mathrm{C}$ ( $60.1^{\circ} \mathrm{F}$ ). Ground vegetation was predominately salal with lesser amounts of Oregon grape, bracken fern, red huckleberry and willow.

As with the Sayward Forest installation, the standard LOGS plot layout was enhanced with treated plot buffer surrounds (Figure 3). Because of the size of the plantation and its uniformity, a series of extra plots were established at the same time. As well, an independent installation was established adjacent to the LOGS site to study the effects of thinning and nitrogen fertilization on stand yields and tree growth processes (Crown and Brett 1975).

Figure 2. Plot layout of the Sayward Forest level-of-growing-stock installation.

## Experimental design

A detailed description of the LOGS study excerpted (and paraphrased) from Williamson and Staebler (1971) is included in Appendix 1. In summary, each installation in the LOGS study plan consists of twenty-seven 0.081-ha ( $1 / 5$-acre) square plots which allows for the testing of eight thinning regimes against a control; there are three replications of each treatment regime in a completely random design. After an initial calibration thinning, treatments assigned to the thinned plots are defined in terms of retained percentages of the gross basal area increment observed on the control plots. The treatments, after a calibration period, are applied over five subsequent periods; the interval between treatments is based on an average crop tree height increment of 3.1 m ( 10 feet).

Figure 3. Plot layout of the Shawnigan Lake level-of-growing-stock installation.

## Stand treatments

In order to allow comparisons, the initial calibration stocking density and the subsequent thinning treatments were rigidly controlled.

## Calibration thinning

An initial calibration thinning was done on the 24 treatment plots to bring them to a common stocking. The stocking density was chosen so that the remaining trees would have abundant space for development during the interval to the first treatment thinning. The calibration stocking target was specified in the study plan using the formula:

$$
\mathrm{S}=0.6167 \times \mathrm{QMD}+8
$$

where $S$ is the average spacing in feet and QMD is the quadratic mean diameter of the leave trees. Prior to estimating the QMD, crop trees - well-formed, uniformly spaced, dominant trees - were selected at a rate of 198 stems/ha (80/acre). Non-crop leave trees were then selected according to study criteria, i.e., no trees should be retained whose diameter was less than one-half the average diameter of the crop trees, and spacing of leave trees should be as uniform as possible.

The study plan further specified rigid guidelines, dependent on the control criterion chosen: when control criterion was the number of trees, the average diameter of leave trees should be within $15 \%$ of the installation mean; when control criterion was basal area, average diameter of leave trees should be within $10 \%$ of the installation mean.

## Treatment thinnings

The eight thinning regimes tested differ in the amount of basal area allowed to accumulate in the growing stock. The amount of growth retained at any thinning is a predetermined percentage of the gross increase found in the unthinned plots since the last thinning (see Table 1 on the inside front cover). The average residual basal area for all thinned plots after the calibration thinning is the foundation upon which all future growing stock accumulation is based. As used in the study, control plots may be thought of as providing a local gross yield table for the study area.

Thinning guidelines were as follows:

1. No crop tree may be cut until all non-crop trees have been cut (another tree may be substituted for a crop tree damaged by logging or killed by natural agents).
2. The quadratic mean diameter of cut trees should approximate that of trees that are available for cutting. This results in a d/D ratio (ratio of diameter of trees cut to diameter of available trees for cutting) of less than 1.0 , and this can be characterized as a crown thinning. The $\mathrm{d} / \mathrm{D}$ ratios were calculated for both installations (Sayward 0.85: Shawnigan 0.82 ) with no clear trends over time and treatment.
3. The diameters of cut trees should be distributed across the full range of trees available for cutting.

## Study supplement - density variation

At establishment, variations on the initial calibration densities were initiated.

At Sayward, four plots were established with a higher initial calibration density - 1223 stems/ha (495 stems/acre). Two treatment thinning regimes, replicated twice, were applied in 1973, after the completion of the initial calibration period; treatment 5 ("dense50") and treatment 1 ("dense10"). The plots were abandoned in 1975 as a result of program review and left with no further treatment or measurement until the fall of 1999, when they were remeasured. The results are presented with the Sayward summaries.

At Shawnigan, a series of plots were established with two initial calibration densities: a higher initial calibration density ("dense") at 1322 stems/ha ( 535 stems/acre); and a lower initial calibration density ("open") at 704 stems/ha ( 285 stems/acre). As with Sayward, these plots were abandoned in 1975, before the initial calibration period was complete, and left until remeasurement in 1996. The results are presented with the Shawnigan summaries.

## Data collection and summarization

The LOGS study plan detailed the data collection protocol for all installations.

At establishment, each tree was identified with a tag, a permanent breast height was marked, and a diameter (dbh) was measured to the nearest 0.1 inches prior to 1975, and to the nearest millimetre thereafter. For each plot, heights were measured on a sample of trees distributed across the diameter range. These measurements were repeated at the end of the calibration period and at the end of each subsequent treatment period. Measurement dates for Sayward Forest are 1969, 1973, 1977, 1981, 1987, 1993 and 1999; for Shawnigan Lake the measurement dates were 1970, 1976, 1982, 1989, and 1996.

Total volume, inside bark, was calculated in cubic feet for each height sample tree by the volume equation of Bruce and DeMars (1974). Total volume was estimated for each tree by regressions of logarithm of volume on logarithm of dbh fit to the height sample tree measurements for each plot and measurement date. Plot volume was then calculated as the sum of the tree volumes. Periodic gross volume and basal area growth was calculated as the difference between live volume and basal area at the start and end of each growth period, plus mortality (and any measurable ingrowth, in the control plots only).

Other reports in the LOGS series (Marshall et al. 1992; Curtis and Clendenen 1994; Hoyer et al. 1996 ) have provided summarization by "merchantable volumes" to illustrate the implications of treatment results on future value. Utilization standards differ throughout the region and have changed many times since the establishment of the cooperative, making comparisons of merchantable volumes between installations difficult. However, characterizations of merchantable volumes are valuable in making comparisons between treatments within an installation to further illuminate their differences. In this report, merchantable volumes were summarized for each treatment using the calculated total tree volumes of all trees with a diameter greater than 17.5 cm ( 6.93 inches). Periodic diameter increment was calculated for trees surviving to the end of each period (Curtis and Marshall 1989).

Capitalizing on the experience gained elsewhere with the establishment of the previous seven LOGS installations, additional measurements of note were taken at both Sayward and Shawnigan Lake. All trees at both installations were stem mapped on an x-y coordinate system. Height-to-live crown was measured on all trees at both installations at establishment, and on a sample at Shawnigan 1996 and at Sayward in 1999.

As well, results from other LOGS sites indicate limitations in some original measurement variables. To overcome these limitations, additional stand development categories were calculated.

At establishment, the study plan called for the selection of designated crop trees (well-formed, uniformly spaced, dominant trees) at a rate of 16 per plot (198/ha; 80/acre). Two additional stand development variables were calculated for comparison with the crop tree variable: L198, the largest 198 trees per hectare ( $80 /$ acre) by diameter; and L99, the largest 99 trees per hectare (40/acre) by diameter. Both additional variables were calculated by substituting mean volume and diameter of the largest 16 trees by diameter (L198), and the largest 8 trees by diameter (L99), per plot in the Bruce and De Mars (1974) volume equation and solving for height (Curtis and Marshall 1986; Curtis 1992; Marshall et al. 1992; Curtis and Clendenen 1994).

Mean annual increment (mai) and periodic annual increment (pai) were not specifically considered in the original study plan. However, previous results in the LOGS series have shown that the general trends in pai and mai are consistent across plots, treatments and installations (Curtis et al. 1997) and therefore have been included here.

## Analyses

The study plan called for an analysis of variance (ANOVA) for each installation upon completion of the full treatment schedule. Of the two CFS/BCMOF installations, only Sayward has reached this point, and the results of the ANOVA are reported here. As well, results to date for both installations are presented in graphical and tabular form in a similar format to other installation results.

## Results

## Summary tables

Summary tables, in metric and imperial measure, for both installations are given in Appendix 2.
Plot statistics and treatment statistics for the live stand at each measurement are summarized in Tables 2a-5b and Tables $6 a-9 b$, respectively, for Sayward, and in Tables 10a-13b and Tables 14a-17b, respectively, for Shawnigan Lake.

## Trends in live stand statistics

## Number of trees

Trends over time by treatment in trees per unit area are shown in Figure 4a (Sayward) and 4b (Shawnigan). The corresponding numerical values are given in Tables 6 (Sayward) and 14 (Shawnigan). Initial stocking of treatment plots after calibration was uniform in both installations. To date, the numbers of remaining trees reflect the levels of thinning as dictated by treatment parameters and the trend is consistent with other installations. The decrease in numbers of trees in the treated plots reflects the trees removed through thinning, while the decrease in the control is through suppression mortality. Tree numbers for the supplemental treatments at both Sayward and Shawnigan show a slight decline through root rot mortality over time.

Figure 4a. Number of live trees by treatment over time - Sayward.

Figure 4b. Number of live trees by treatment over time - Shawnigan.

## Diameter development

Trends over time by treatment in QMD are shown in Figures 5a (Sayward) and 5b (Shawnigan). The corresponding numerical values are given in Tables 7 (Sayward) and 15 (Shawnigan). The QMD response over time is consistent with results from other installations. At calibration, the QMD for the treatments were, by design, essentially the same, while the lesser control value reflects the large number of understorey, small-diameter trees. The response to treatments is as expected; lower densities produce larger diameter trees.

Figure 5a. Quadratic mean dbh by treatment over time - Sayward.

Figure 5 b. Quadratic mean dbh by treatment over time - Shawnigan.

## Basal area

Trends over time by treatment for basal area are shown in Figure 6a (Sayward) and 6b (Shawnigan). The corresponding numerical values are given in Tables 8 (Sayward) and 16 (Shawnigan). As with diameter response, the initial levels of basal area following calibration were tightly controlled to give a uniform level across treatments. The control value was greater as a reflection of the greater number of stems. The response over time to the treatments has produced a trend consistent with other installations, with the control values still greater than the treatments. Of note is the response of the "dense" and "open" treatments at Shawnigan Lake, both which have produced more basal area than the LOGS treatments; basal area in the "dense" treatment in approaching those of the control.

Figure 6a. Basal area by treatment over time - Sayward.

Figure 6b. Basal area by treatment over time - Shawnigan.

## Relative density measures

Figures 7a (Sayward) and 7b (Shawnigan) show trends of Curtis's (1982) relative density measure, RD, over time for the thinning treatments. The RD values have been reported in previous reports (Curtis and Marshall 1986; Curtis 1992; Curtis and Clendenen 1994; Hoyer et al. 1996) and are included here for comparison purposes. The RD trends at both installations are consistent with those of other installations. The RD trend for each control is included as a reference point for the thinning treatments, and the asymptote represents an estimate of the maximum attainable density in an unthinned stand at each location.

Figure 7a. Relative density $[R D=$ basal area/SQRT(QMD)] by treatment over time - Sayward

Figure 7b. Relative density $[R D=$ basal area/SQRT(QMD)] by treatment over time - Shawnigan

## Total volume

Trends in total volume over time by treatment are shown in Figure 8a (Sayward) and 8b (Shawnigan). The corresponding numerical values are given in Tables 9 (Sayward) and 17 (Shawnigan). Again, the trends are consistent with those of other installations, with the control producing the greatest total volume and the treatment volumes declining with increased level of thinning. Of note at Shawnigan Lake are the current volumes for the "dense" and "open" treatments: both are out-producing other treatments and, in the case of the "dense" treatment is outproducing the control.

Figure 8a. Volume by treatment over time - Sayward.

Figure 8b. Volume by treatment over time - Shawnigan.

## Crop tree

At establishment, prior to the initial thinning, designated crop trees were selected at a rate of 198 per ha ( 80 per acre). Crop trees were selected on a combination of vigor and spacing with the intent that they would form the final crop, and, as such, these trees were favored throughout the treatment process. They were uniformly distributed and were not necessarily among the largest 198 per ha ( 80 trees per acre). The reasoning for crop selection was to provide a common measurement element with relative continuity through all the treatments and allow comparability among installations. However, as reported from a number of other installations, the effectiveness of such comparisons has diminished with replacement of crop trees over time because of damage or poor vigor. Height sampling, sample size and height estimations are an important variable in assessing growth results due to thinning, and there
are drawbacks with the original height sample methodology as reported in earlier LOGS reports (Curtis 1992; Curtis and Marshall 1986). Crop tree comparisons by treatment over time are shown in Tables 18 (Sayward) and 19 (Shawnigan).

## Height development

Height trends by treatment over time are presented in Figures 9a (Sayward) and 9b (Shawnigan) and are summarized in Tables 20 (Sayward) and 21 (Shawnigan). There appears to be no relation to thinning treatment.

Figure 9a. Height comparison by treatment over time - Sayward.

Figure 9b. Height comparison by treatment over time - Shawnigan.

## Live crown development

Live crown development by treatment over time is presented in Figures 10a (Sayward to 1999) and 10b (Shawnigan to 1996). The results are similar to those from other installations (Curtis 1992; Marshall et al. 1992; Curtis and Clendenen 1994), with longer live crowns associated with lower density treatments.

Figure 10a. Live crown ratio by density for selected treatments - Sayward.

Figure 10b. Live crown ratio by density for selected treatments - Shawnigan.

## Cumulative volume production

Cumulative volume results are presented in Figure 11 and Table 22 (Sayward) and in Figure 12 and Table 23 (Shawnigan). Volume removed during thinning is included in the increment for each thinning period. Volume removed at calibration has not been included. Mortality in the treatments was minor and has been rolled into a total mortality volume to date for each treatment. As mortality is becoming an increasingly important factor in the development of the control, control mortality is listed for each treatment period and these data are identified with footnotes.

Figure 11. Cumulative volume to age 52 - Sayward.

Figure 12. Cumulative volume to age 51 - Shawnigan.

## Stand development

Stand development results for both installations are presented in Tables 24 to 27. Stem density distribution by tree size class for each treatment is presented in Tables 24 (Sayward) and 26 (Shawnigan). Volume distribution by tree size class for each treatment is presented in Tables 25 (Sayward) and 27 (Shawnigan). Included in the tables are treatment totals for all live trees and those in the "merchantable" dbh class. Merchantable class is defined as live trees larger than 17.5 cm dbh ( 6.8 inches dbh). As well, average dbh for all merchantable stems per treatment is listed.

The current total stem volume for all live trees by treatment for both installations is compared with merchantable volume in Figures 13a and b. To date, none of the treatments has exceeded the control in total volume production, with the exception of the "dense" supplemental treatment at Shawnigan. However, a number of treatments are nearing or have surpassed the control when merchantable volumes are compared.

Figure 13a. Volume by treatment at age 52 - Sayward.

Figure 13b. Volume by treatment at age 51 - Shawnigan.

## Periodic annual volume increment (PAI)

Periodic annual volume increment for both installations are presented in Tables 28 (Sayward) and 29 (Shawnigan). Mean annual increments (MAI) are included in both the tables and Figures 14 and 15 to illustrate stand growth responses to the treatments. The trends are consistent with other installations with PAI values about twice the MAI values, indicating in both stands the treatments are far from culmination.

Figure 14a. Sayward pai and mai volume (fixed treatments).

Figure 14b. Sayward pai and mai volume (increasing and decreasing treatments).

## Analysis of variance

The original study plan (Williamson and Staebler 1965) called for an analysis of variance (ANOVA) testing differences among treatments in gross basal area periodic annual increment and growth percent, gross total stem volume periodic annual increment and growth percent, and, survivor QMD periodic annual increment (Table 30). The ANOVA results (Table 31) are generally consistent with those from other LOGS installations at the end of the full treatment schedule (Marshall et al. 1992; Hoyer et al. 1996; Curtis and Clendenen 1994).

Figure 15a. Shawnigan pai and mai volume (fixed treatments).

Figure 15b. Shawnigan pai and mai volume (increasing and decreasing treatments).

## Discussion

Both installations were the last to be established in the cooperative and only Sayward has reached the end of the planned treatment schedule. The Shawnigan Lake installation is at least 10 years from completion. However, treatment results to date are similar to those from other LOGS installations (Curtis and Marshall 1986), and generally differ from the more productive sites only in the rate and degree of response associated with a lower site quality.

The LOGS treatments were designed to examine the relationship of growth to growing stock on a stand and individual tree basis and were never intended as a comparison of operationally feasible thinning regimes. In evaluating the results of the faster-growing, higher-site installations, earlier discussions have indicated, with hindsight, the need of a treatment consisting of a calibration cut only to allow a comparison with the LOGS treatment results and a common operational thinning density (Curtis et al. 1997). The resurrected supplemental treatments that studied density variation at both Sayward and Shawnigan offer some results that allow these comparisons.

The original purpose of the supplemental density variation treatments was to test the effect of differing initial densities on subsequent growth. When they were abandoned in the mid 1970s, the planned LOGS treatment schedule was never applied at Shawnigan and the plots at Sayward only received one treatment entry in 1973 (dense50, dense10). Therefore, the supplemental density variation results can be viewed as an operationally feasible pre-commercial thinning treatment.

Earlier results have revealed some difficulties in making meaningful comparisons across installations (Curtis et al. 1997) because of the range of initial densities among installations and the now-known relationship of gross growth of unthinned stands to density. However, treatment results within an installation are comparable because the treatments were defined on the basis that the control growth represents the site potential. Therefore, the results of the supplemental density variation treatments at each installation are comparable to the other treatments within the installation. As well, an argument can be made for some reasonable inferences when comparing the results of the density variation treatments between Sayward and Shawnigan based on the similarity in their initial stand densities (2624 stems/ha at Sayward; 2945 stems/ha at Shawnigan).

The original LOGS study plan and objectives were derived from a widely held assumption that essentially the same volume production could be produced over a wide range of stand densities (the Langsaeter hypothesis), with thinning merely redistributing a constant volume increment among a varying number of trees. The treatments were designed to test this assumption and to identify the density regime where the minimum amount of growing stock feasible would be retained without major growth loss. The results from the earlier and more productive site installations (Hoyer et al. 1996; Curtis and Clendenen 1994; Curtis 1992; Marshall et al. 1992; Curtis and Marshall 1986) have demonstrated that this assumption does not hold true for young Douglas-fir stands: volume production is strongly related to growing stock. The results from Sayward and Shawnigan confirm this; at this point in time, gross volume production has been greater for the controls than for any thinning treatments (Fig. 8 a and b ) with the exception of the density variation "dense" treatment at Shawnigan. As detailed in Curtis et al. (1997), "increment increases with stocking, though at a decreasing rate up to a point which supression-related mortality becomes important".

Basal area production shows a similar trend to that of volume (Fig. 6), and, as would be expected, the lowerdensity treatments produced larger diameter trees (Fig. 5). Mortality, principally by root rot, has been minimal in the treatments, while mortality in the controls, mainly through suppression of the smaller trees, is increasing and having a significant impact on production (Table 32 - Sayward; Table 33 - Shawnigan).

As with other LOGS findings, trends of net total tree volume MAI and net total tree PAI (Figs. 14 and 15) clearly show that both installations are far from culmination, with current growth rates two and three times that of MAIs (Tables 28 and 29). Harvesting at this young age would involve large losses in total productivity relative to the potential.

The LOGS treatments were designed to examine the relationship of growth to growing stock on a stand and individual tree basis, with the reporting emphasis on a gross production comparison to the untended control. Very few analyses have been done on the value aspect of the treatment effects to produce useable timber, to enhance wood quality, and to consider the management of the non-timber values. A cursory comparison of treatments at this point in time would lead to the conclusion that there is little to gain from thinning (Fig. 8). However, when merchantable volume production, the effects on stand structure, and potential wood quality gains through live crown manipulation are compared, the returns from some thinning regimes are substantial.

Merchantable volume production in several thinning regimes is approaching or has exceeded the control (Fig. 13), and trends indicate further gains as suppression mortality continues to erode the diminishing productivity of the control. As in other installations, treatment 7 holds the most promise in competing with the control. Of particular interest, are the results of the supplemental density variation treatments at each installation, and the differences in these results between installations. As mentioned, the treatments are assessed by comparing their performance to the site potential as represented by the control. At the Sayward installation (of medium site quality), the two "dense" treatments have not overtaken the control or treatment 7 in total or merchantable volume, while at the Shawnigan installation (of lower site quality), the "dense" treatment has surpassed all treatments including the control in both total and merchantable volume and the "open" treatment has surpassed the control and treatment 7 in merchantable volume.

Treatment results so far are similar to those from other LOGS installations, generally differing only in the rate and degree of response associated with site productivity. This difference in site productivity is evident in looking at the stand structure of the controls at both installations (Figure 16; Tables 25a through 27b). The low-site Shawnigan installation carries a significant portion of its growing stock in smaller trees (less than 17.5 cm dbh ) which are more susceptible to suppression mortality and contribute little to growth potential. At the higher-site Sayward installation, the diameter distribution is more normal, with a lesser portion of its growing stock in small, suppressed trees. This suggests that there is a better return on the thinning investment on the lower site where the remaining growing stock can better utilize the biological advantages obtained from thinning and further exploit the natural decline in productivity through growth stagnation and suppression mortality of the less forgiving lower site, as evidenced in the control.

Figure 16. Comparison of control stand density by diameter class distribution for Sayward (age 52) and Shawnigan (age 51).

Live crown development by treatment over time at both installations is consistent with results from others (Marshall et al. 1992; Curtis and Clendenen 1994)). Results clearly show the effects of live crown manipulation through thinning (Fig. 10). There is a strong relationship between stocking density and length of live crown. As outlined by Brix (1993), "the crown is the factory of the tree and in stand tending we attempt to influence the size and efficiency of the crown". In addition, live crown ratio has a direct influence on wood quality, through the production and location within the tree bole of juvenile wood (Jozsa and Middleton 1994); longer live crowns produce more pronounced stem taper and a higher proportion of juvenile wood.

From a practical point of view, the results validate and clarify the benefits of thinning in stand management and offer a number of options in influencing productivity and value. At Shawnigan, the "dense" treatment, essentially a precommercial thinning, produced a stand with a live crown ratio and basal area similar to the control, with a higher yield in total and merchantable volume production, and perhaps with increased log value due to a smaller proportion of juvenile wood relative to mature wood. As well, harvesting costs would be reduced with fewer nonmerchantable stems, a greater number of merchantable stems, and more efficient handling through larger piece sizes.

Even at this young age, the thinning treatments at both installations have produced stands that differ widely in appearance, tree size, crown characteristics and understorey development. The potential for further gains through an even moderately extended rotation would increase both volume and value of timber while creating stands and landscapes with increasing non-timber values.

Sayward has completed the original treatment schedule, and, as agreed by the LOGS cooperative, will continue to be maintained and measured into the future. Shawnigan was the last LOGS site to be established and will not complete the original treatment schedule for another 10 years. The LOGS study, through the cooperative, has answered a number of questions relevant to timber production first posed in the 1960s. Today, the silvicultural value of the installations continue to increase with the passage of time, and these sites have the potential to answer other questions raised by today's industrial, environmental, and social issues.

As outlined in Curtis et al. (1997), the LOGS installations have both continuing demonstration value and research uses beyond those discussed in the original plan. These include:

- evaluating trends in MAI and PAI in relation to age and treatment in answer to current questions about rotations and possible management options for reducing conflicts between timber production and other forest values;
- contributing to wildlife and biodiversity concerns by quantifying the visually striking differences in understorey composition and development among treatments and among sites;
- evaluating the effects of thinning on wood quality and value;
- demonstrating the enormous influence that thinning can have on stand development patterns and stand characteristics, even over a relatively short period; and,
- offering effective and visually striking examples of some alternatives for enhancing aesthetics and understory vegetation and stand structure while maintaining or enhancing timber values.

Of equal value and importance is the success of the cooperative itself. Long-term research projects have always been difficult to create and maintain, more so in recent years. The LOGS Cooperative is a successful example of an international, multi-agency, long-term research project carried out with a minimal bureaucracy. It has endured for more than 30 years through personnel changes, funding uncertainties, policy changes and the complacency of the status quo in silvicultural and mensurational research.

## Appendix 1

Description of Experiment

The following information is excerpted (and paraphrased) from Williamson and Staebler (1971).
The experiment is designed to test a number of thinning regimes beginning in young stands made alike at the start through a calibration thinning. Thereafter, through the time required for 60 feet of height growth, growing stock is controlled by allowing a specified addition to the growing stock between successive thinnings. Any extra growth is cut and is one of the measured effects of the thinning regime.

A single experiment consists of eight thinning regimes plus unthinned plots whose growth is the basis for treatment in these regimes. There are three plots per treatment arranged in a completely randomized design for a total of 27 plots of one-fifth acre each.

Well formed, uniformly spaced, dominant trees at the rate of 80 per acre, or 16 per plot, are designated as crop trees before initial thinning. Each quarter of the plot must have no fewer than three suitable crop trees or no more than five - another criterion for stand uniformity.

All 24 treated plots are thinned initially to the same density to minimize the effect of variation in original density on stand growth. Density of residual trees is controlled by quadratic mean diameter (diameter of tree of average basal area) of the residual stand according to the following formula,

Average spacing in feet $=(0.6167 \times \mathrm{QMD})+8$.
If one concentrates on leaving a certain amount of basal area corresponding to an estimated averall QMD, then the residual number of trees may vary freely and the actual QMD may differ among plots plus or minus $10 \%$. Alternately, if emphasis is on leaving a certain number of trees to correspond to an estimated overall QMD, then the basal area can differ among plots and the actual QMD may vary plus or minus $15 \%$ between plots.

The eight tested thinning regimes differ in the amount of basal area allowed to accumulate in the growing stock. The amount of growth retained in any thinning is a predetermined percentage of the gross increase found in the unthinned plots since the last thinning (Table 1, inside the front cover). The average residual basal area for all thinned plots after the calibration thinning is the foundation upon which all future growing stock accumulation is based. As used in the study, control plots may be thought of as providing a local gross yield table for the study area.

Thinnings will be made (after the calibration thinning) whenever average height growth of the crop trees comes closest to each multiple of 10 feet above the initial height.

As far as possible, type of thinning is eliminated as a variable in the treatment thinnings through several specifications.

1. No crop tree may be cut until all noncrop trees have been cut (another tree may be substituted for a crop tree damaged by logging or killed by natural agents).
2. The QMD of cut trees should approximate that of trees available for cutting.
3. The diameters of cut trees should be distributed across the full diameter range of trees available for cutting.

10b Number of live trees per acre by treatment, plot, treatment period,
year and stand age (years) - Shawnigan . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 40
11a Quadratic mean dbh (cm) of all lives trees by treatment, plot, treatment period,
year and stand age (years) - Shawnigan . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 41
11b Quadratic mean dbh (inches) of all lives trees by treatment, plot, treatment period,
year and stand age (years) - Shawnigan . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 42
12a Basal area $\left(\mathrm{m}^{2} / \mathrm{ha}\right)$ of all live trees by treatment, plot, treatment period,
year and stand age (years) - Shawnigan . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 43
12b Basal area ( $\mathrm{ft}^{2} /$ acre) of all live trees by treatment, plot, treatment period,
year and stand age (years) - Shawnigan . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 44
13a Total volume ( $\mathrm{m}^{3} / \mathrm{ha}$ ) of all live trees by treatment, plot, treatment periods,
year and stand age (years) - Shawnigan . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 45
13b Total volume (ft ${ }^{3} /$ acre $)$ of all live trees by treatment, plot, treatment periods,
year and stand age (years) - Shawnigan . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 46
14a Number of live trees per hectare by treatment, treatment period, year and stand age (years) - Shawnigan ..... 47
14b Number of live trees per acre by treatment, treatment period, year and stand age (years) - Shawnigan ..... 47
15a Quadratic mean $\mathrm{dbh}(\mathrm{cm})$ of all live trees by treatment, treatment period, year and stand age (years) - Shawnigan ..... 48
15b Quadratic mean dbh (inches) of all live trees by treatment, treatment period, year and stand age (years) - Shawnigan ..... 48
16a Basal area ( $\mathrm{m}^{2} / \mathrm{ha}$ ) of all live trees by treatment, treatment period, year and stand age (years) - Shawnigan ..... 49
16b Basal area ( $\mathrm{ft}^{2} / \mathrm{acre}$ ) of all live trees by treatment, treatment period, year and stand age (years) - Shawnigan ..... 49
17a Total volume ( $\mathrm{m}^{3} / \mathrm{ha}$ ) of all live trees by treatment, treatment periods, year and stand age (years) - Shawnigan ..... 50
17b Total volume ( $\mathrm{ft}^{3} / \mathrm{acre}$ ) of all live trees by treatment, treatment periods, year and stand age (years) - Shawnigan ..... 50
18a Crop tree comparison per hectare, by treatment, over time - Sayward ..... 51
18b Crop tree comparison per acre, by treatment, over time - Sayward ..... 52
19a Crop tree comparison per hectare, by treatment, over time - Shawnigan ..... 53
19b Crop tree comparison per acre, by treatment, over time - Shawnigan ..... 54
20 Crop tree height comparison by treatment over time - Sayward ..... 55
21 Crop tree height comparison by treatment over time - Shawnigan ..... 55
22a Cumulative volume ( $\mathrm{m}^{3} / \mathrm{ha}$ ) by treatment - Sayward ..... 56
22b Cumulative volume ( $\mathrm{ft}^{3} / \mathrm{acre}$ ) by treatment - Sayward ..... 56
23a Cumulative volume ( $\mathrm{m}^{3} / \mathrm{ha}$ ) by treatment - Shawnigan ..... 57
23b Cumulative volume ( $\mathrm{ft}^{3} / \mathrm{acre}$ ) by treatment - Shawnigan ..... 57
24a Density distribution (stems/ha) by tree size class 1999 (stand age 52) - Sayward ..... 58
24b Density distribution (stems/acre) by tree size class 1999 (stand age 52) - Sayward. ..... 58
25a Volume distribution ( $\mathrm{m}^{3} / \mathrm{ha}$ ) by tree size class 1999 (stand age 52) - Sayward ..... 59
25b Volume distribution ( $\mathrm{ft}^{3} /$ acre) by tree size class 1999 (stand age 52) - Sayward ..... 59
26a Density distribution (stems/ha) by tree size class 1996 (stand age 51) - Shawnigan ..... 60
26b Density distribution (stems/acre) by tree size class 1996 (stand age 51) - Shawnigan . ..... 60
27a Volume distribution ( $\mathrm{m}^{3} / \mathrm{ha}$ ) by tree size class 1996 (stand age 51) - Shawnigan ..... 61
27b Volume distribution ( $\mathrm{ft}^{3} /$ acre ) by tree size class 1996 (stand age 51) - Shawnigan ..... 61
28a Periodic Annual Increment (PAI) and Mean Annual Increment (MAI) - Volume ( $\mathrm{m}^{3} /$ ha/year) - Sayward ..... 62
28b Periodic Annual Increment (PAI) and Mean Annual Increment (MAI) - Volume (ft ${ }^{3} /$ acre/year) - Sayward ..... 62
29a Periodic Annual Increment (PAI) and Mean Annual Increment (MAI) - Volume ( $\mathrm{m}^{3} / \mathrm{ha}$ /year) - Shawnigan ..... 63
29b Periodic Annual Increment (PAI) and Mean Annual Increment (MAI) - Volume (ft ${ }^{3} /$ acre/year) - Shawnigan ..... 63
30 Analysis of Variance - Sayward ..... 64
31 Analysis of variance results for periodic annual gross volume increment and growth percent, periodic annual gross basal area increment and growth percent, and survivor quadratic mean diameter periodic annual increment - Sayward ..... 64
32a Mortality by treatment and treatment period - Sayward Forest ..... 65
32b Mortality by treatment and treatment period - Sayward Forest ..... 65
33a Mortality by treatment and treatment period - Shawnigan Lake ..... 66
33b Mortality by treatment and treatment period - Shawnigan Lake ..... 66

## The Pacific Forestry Centre, Victoria, British Columbia

The Pacific Forestry Centre of the Canadian Forest Service undertakes research as part of a national network system responding to the needs of various forest resource managers. The results of this research are distributed in the form of scientific and technical reports and other publications.
Additional information on $N$ atural Resources Canada, the Canadian Forest Service, and Pacific Forestry Centre research and publications is also available on the W orld Wide W eb at http://www.pfc.cfs.nrcan.gc.ca/.

## Canadian Forest Service Contacts

For more information about the Canadian Forest Service, visit our website at http://www.nrcan.gc.ca/cfs-scf/ or contact any of the following Canadian Forest Service establishments

Atlantic Forestry Centre
