Recent Migration Patterns in Rural and Small Town Canada

1. Introduction

Migration is a concern for Rural and Small Town (RST) areas of Canada as rural development is essentially a demographic phenomenon. To date, there has been little analysis of migration patterns and their affect on RST areas. To better understand the contribution that movers have on the RST population, this paper documents migration into and out of RST Canada. Specifically, the characteristics of the moving population that are 15 years of age and over are examined, with a focus on their levels of human capital. In addition, characteristics of migrating youth are discussed as youth can be seen as an indicator of the state of rural areas and are a key factor in rural development. The understanding of the patterns of migration may give rise to solutions for the retention of human capital in rural and small town areas and the promotion of rural development.

2. Definitions, data and approach

For the purpose of this paper, LUC (*larger urban centres*) refers to the population living in census metropolitan areas (CMAs) and census agglomerations (CAs) (box 1).

Box 1 'Rural and Small Town' (RST)

Rural and Small Town (RST) refers to the population living outside the commuting zone of Larger Urban Centres (LUCs) – specifically, outside Census Metropolitan Areas (CMA) and Census Agglomerations (CA). RST includes all municipalities with urban populations of 1,000 to 9,999 and rural areas, where less than 50 percent of the employed individuals commute to the urban core of a CMA/CA.

A CMA has an urban core of 100,000 or over and includes all neighbouring municipalities where 50 percent or more of the labour force commutes to the urban core. A CA has an urban core of 10,000 to 99,999 and abides by the same commuting rule as a CMA.

The data in this report was derived from the Canadian Census of Population of 1971, 1976, 1981, 1986, 1991 and 1996. Each of these censuses employed a migration question, which asked "Where did this person live 5 years ago?" At the Canada level, the responses to this question allowed the identification of four groups:

1. RST non-movers;

- 2. LUC non-movers;
- 3. RST out-migrants to LUC; and
- 4. RST in-migrants from LUC.

At the provincial level, the analysis was more complicated. The provincial migration figures required the identification of 8 groups:

- 1. RST non-movers:
- 2. LUC non-movers;
- 3. RST out-migrants to same province LUC;
- 4. RST out migrants to different province LUC;
- 5. RST out-migrants to different province RST;
- 6. RST in-migrants from same province LUC;
- 7. RST in-migrants from different province LUC; and
- 8. RST in-migrants from different province RST.

It should be noted that the inclusion of inter-provincial RST-to-RST movers in the provincial level analysis means that the results are not fully compatible with the Canada-level figures. Specifically, group number 5 and group number 8 are treated as RST non-movers at the Canada level¹. Movers from outside of Canada and institutional residents were not included in the analysis.

A major focus of the analysis is the impact of migration on human capital. Human capital can be thought of as the education, experience and abilities of the population. To give an insight into these qualities, migration rates were examined by age, highest level of educational attainment, and labour force activity. To further focus the analysis on human capital, only individuals 15 years of age and over were included. The age and characteristics of individuals were those pertaining at the end of each census period.

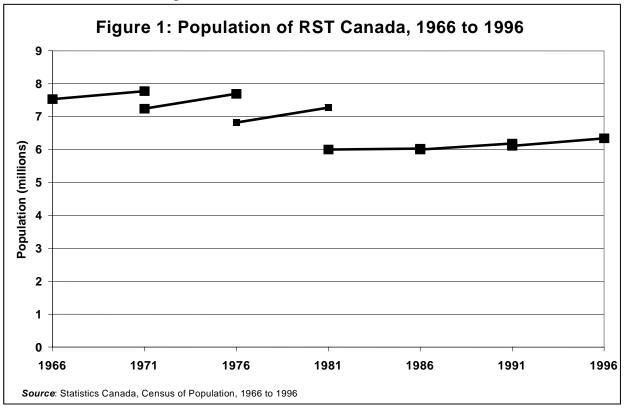

3. Background

Using "current" boundaries (i.e. not adjusting for boundary changes and utilising the data published for the boundaries in effect in the given year), Canada's RST population decreased over the 1966 to 1996 period. This fact is illustrated in Figure 1 – compare the 7.8 million RST population in 1971 according to the 1971 geographic boundaries with the 6.3 million RST in 1996 according to the 1996 boundaries.

However, each line segment in Figure 1 is sloping upward. Thus, within "constant" boundaries, there was population growth in RST Canada during each intercensal period from 1966 to 1996. This RST growth was not sufficient to counter the loss due to reclassification. In fact, boundary

¹ While the methodology used to generate the provincial level data required the identification of all these groups, this data was aggregated to give total in-, out- and net migration in the charts throughout this paper.

changes reclassified over 2 million Canadians from RST to LUC, resulting in 19 percent less RST residents in 1996 compared to 1971.

4. Canadian migration trends, 1966 to 1996

Consistent with the American experience (e.g. Fulton *et al*, 1979) there was rural NET OUT-migration at the end of the 1960s. In the 1966 to 1971 period, RST areas experienced a net loss of over 362,000 persons. This was the largest net out-migration recorded in the study period and was equivalent to 6.5 percent of the base RST 1966 population (Figure 2 and Table 1)².

² Note that Figure 1 indicates that the RST population (for all age groups) increased by about 237,000 persons between 1966 and 1971 (see the Appendix to Mendelson and Bollman, 1998b). This calculation indicates that, for the population 15 years of age and older in 1971, 362,000 more individuals moved out of RST areas than moved into RST areas. This apparent discrepancy is due to a number of factors:

[•] Table 1 refers to individuals 15 years of age and older at the end of the period (1971 in this example). Thus, the migration of children 5 to 14 years of age are not included in Table 1.

[•] Children born in the previous 5 years are included in the population levels (Figure 1) but are not included in the migration data.

[•] International migration into and out of Canada is not included in Table 1 but is included in the population trends in Figure 1.

In the 1971-1976 period net migration flows reversed and RST areas had a net gain of 50,000. Net gains continued in the 1976-1981 period with the flow decreasing slightly to 47,000. This reversal of the previous pattern was labelled "the population turnaround" in the USA. During the 1970s, **rural NET IN-migration** was due to:

- lower out-migration (i.e. higher rural retention); and
- higher in-migration.

There was another turnaround in migration between 1981 and 1991. In the 1981 to 1986 intercensal period, RST areas experienced a net loss of 112,000. In the 1986 to 1991 period, RST Canada experienced a much smaller net loss (2,000). This period had the smallest net population change. These two intercensal periods have been labelled the "turnaround of the turnaround" when there was a return to the pattern of rural NET OUT-migration. This was due to:

• lower in-migration (in the 1981 to 1986 period).

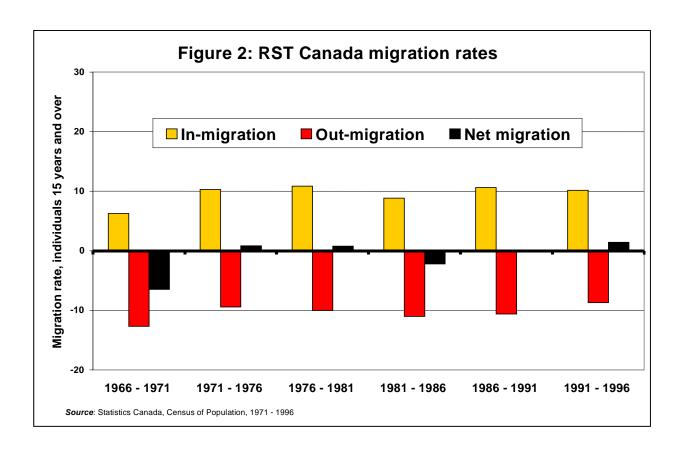

The data for the first part of the 1990s indicated a return to the pattern of the 1970s with **rural NET IN-migration**. However, the components of this net rural in-migration differed from the situation of the 1970s. Similar to the American situation, rural in-migration did not increase. Rather, the net rural in-migration was due to:

• lower out-migration (i.e. higher rural retention).

Interestingly, for twenty years from 1971 to 1991, the RST to LUC flow (i.e. gross rural outmigration) was relatively stable in absolute terms (between 554,000 and 600,000 over each five year period). The reduced outflow in the 1991 to 1996 period (470,000, which is 84,000 less than in any other period since 1971) was the major factor that provided rural NET IN-migration in this period.

Since 1971, the LUC to RST flow (i.e. gross rural in-migration) was over 545,000 in all periods except in the 1981 to 1986 period when the flow was 451,000 (94,000 less than any other period since 1971). This reduction in inflow was the major factor that provided rural NET OUT-migration between 1981 and 1986.

Throughout most of the study period, relatively small changes in the rate of RST in-migration caused the swings in the rate and direction of net migration. The exception to this was the 1991 to 1996 period when a reduction in the rate of out-migration resulted in RST NET IN-migration.

Note: RST In-migration rate = (LUC-to-RST) / (RST non-movers)+(RST-to-LUC) * 100

RST Out-migration rate = (RST-to-LUC) / (RST non-movers)+(RST-to-LUC) * 100

LUC In-migration rate = RST-to-LUC / (LUC non-movers)+(LUC-to-RST) * 100

LUC Out-migration rate = (LUC-to-RST) / (LUC non-movers)+(LUC-to-RST) * 100

5. Provincial migration patterns, 1966 to 1996

5.1 Provincial Out-migration

Provinces with low RST out-migration rates tended to have relatively low RST out-migration rates in all periods (Table 2). After 1971, the four Atlantic Provinces consistently displayed the lowest rates of out-migration from RST areas. The only exception was Newfoundland and Labrador, in the 1991 to 1996 period, when it had the fourth highest out-migration rate.

Provinces with high RST out-migration rates presented a more confusing picture. In the 1986 to 1996 period, British Columbia and Alberta have had the highest rates. However, Alberta had much lower relative figures in the 1971 to 1981 period. British Columbia retained a relatively high rate between 1976 and 1981, but had a relatively lower rate between 1971 and 1976.

After 1966, two-thirds of the highest RST out-migration provinces were western provinces. Thus the typical out-migration pattern is:

- Atlantic Provinces have relatively lower RST out-migration rates
- Quebec and Ontario have mid-range RST out-migratin rates; and
- Western Provinces have relatively higher RST out-migration rates.

5.2 Provincial In-migration

Provinces with low rates of RST in-migration tended to have relatively low rates of in-migration in all periods (Table 3). The Atlantic Provinces and Saskatchewan had low rates of in-migration throughout the study period, with Newfoundland consistently experiencing the lowest rates of all.

Unlike the out-migration rates, the provinces with high in-migration rates presented a more consistent pattern. In each period, British Columbia, Ontario and Alberta had the highest rates of RST in-migration.

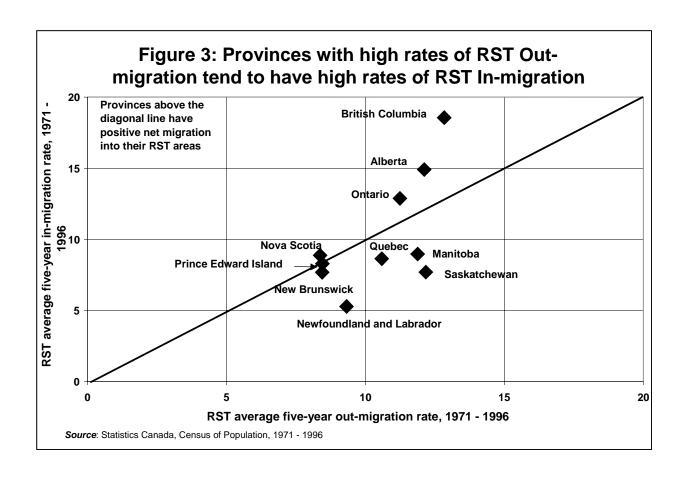

| Table 3: | Table 3: RST areas of provinces ranked by rate of in-migration (percent) | | | | | | | | | | | | |

| Source: Statis | stics Cana | ada, Census | of Population | on, 1971 - 19 | 96 | | | | | | | | |

Provinces with the highest rates of RST out-migration also tended to have the highest rates of RST in-migration. Figure 3 shows the provinces plotted by their average rate of out-migration³ (i.e. the last column of Table 2 is plotted on the horizontal axis) and by their average rate of in-migration (i.e. the last column of Table 3 is plotted on the vertical axis).

There was a strong correlation between rates of RST out-migration and rates of RST inmigration. The provinces with the highest turnover rates (i.e. high rates of in-migration and outmigration) were British Columbia, Alberta and Ontario. The provinces with the lowest turnover rates were the Atlantic Provinces.

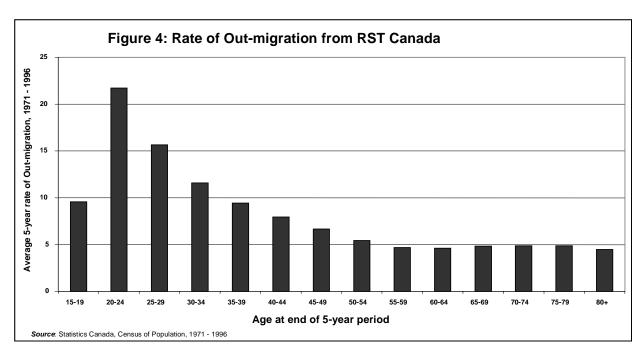

In Figure 3, provinces above the diagonal had, on average, rural NET IN-migration - British Columbia, Alberta and Ontario. The RST areas of these provinces gained population through migration. On the other hand, the RST areas of Newfoundland and Labrador, Saskatchewan, Manitoba and Quebec fared relatively poorly. Their position below the diagonal line indicated that they lost RST population through internal migration. RST Prince Edward Island, Nova Scotia and New Brunswick had low in-migration and low out-migration (i.e. they occupy the lower left position in Figure 3). Their position close to the diagonal line indicates that internal migration did not have a significant positive or negative effect on their RST population.

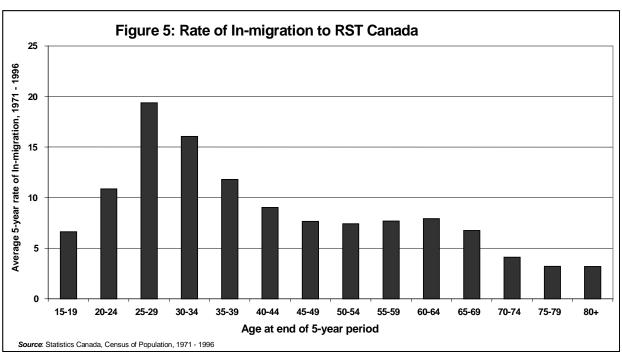

³ Please note that this chart starts with the 1976 census data. This means that only migration from 1971 onwards is included. As already explained, each census looks back over the previous 5 years of migration. The 1971 data (and, thus, the 1966 to 1971 migration figures) were omitted from the analysis as these were at variance with the more general pattern that appeared in the later years.

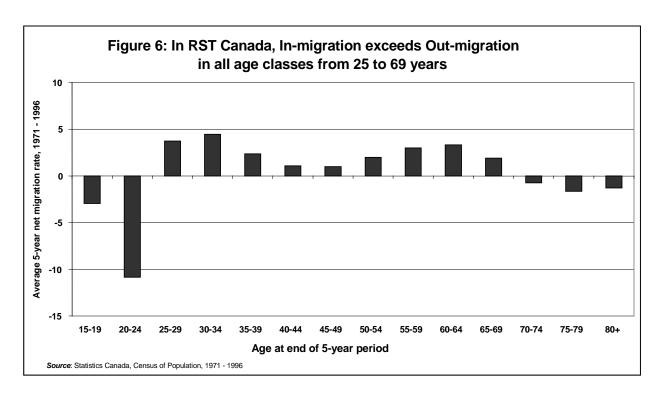

6. Migration Patterns by Age, 1971 to 1996

In general, youth were the most mobile throughout the period 1971 to 1996. Out-migration (Figure 4) was highest in the 20 to 24 year age class. Individuals in their early twenties have high rates of education-related migration compared to the other age groups. Some level of education is necessary for most types of employment and some RST residents must migrate in order to continue their schooling. The rate of in-migration (Figure 5) was highest for the 25 to 29 year age class. These individuals may have been returning after some post-secondary education or they had obtained some employment experience and were returning to a rural area to start a family. Migration rates were generally lower for each older age group.

RST areas were net losers of youth (under 25 years of age) but net gainers of individuals in all age classes from 25 to 69 years of age (Figure 6). Thus, RST areas appeared competitive in attracting migrants in all age classes from 25 to 69 years of age. Note that there was a small but noticeably higher rate of RST in-migration for individuals who may be classified as "early retirees" (in the 55 to 64 year age classes). For individuals 70 years of age and older, more individuals moved out of RST areas than moved into RST areas, although the net rates of migration were relatively small on average. Once again, the 1966 to 1971 migration rates have been excluded from these charts as these figures appear inconsistent with the later data.

In general, the pattern across age groups held in all intercensal periods. Also, within each age group, the rate of migration varied according to the overall pattern of migration (as discussed above). For all age groups (Figure 2, above), the highest rate of out-migration was in the 1981 to 1986 period. However, the highest rate of out-migration for rural youth was in the 1986 to 1991 period (Figure D1 in Appendix D).

Recall that reduced in-migration was the reason for RST NET OUT-migration in the 1981 to 1986 period. The decline in the rate of in-migration in the 1981 to 1986 period was noticeable within each age class (Figure D2). Also, increased in-migration rates since 1986 were evident for all age classes and were particularly evident in the "early retiree" age classes (55 to 64 years).

The return to positive RST net migration in the early 1990s was attributable to increased rural retention rates (i.e. lower out-migration rates). The lower out-migration rate in the 1991 to 1996 period was particularly evident for rural youth and rural young adults (Figure D1).

Within each age group, net migration rates varied significantly across all intercensal periods since the 1971 to 1976 period (Figure D3). In general, for each intercensal period, the conclusion can be restated that RST Canada gains more than it loses from migration for each age class from 25 to 69 years of age. However, the relatively low rate of in-migration in the 1981 to 1986 period caused negative net migration rates for age classes up to 49 years of age. Also, higher in-migration of "early retirees" (aged 55 to 64 years of age) after 1986 boosted their net in-migration rates to a level approaching that of young adults. Thus, in recent periods, rural communities have been attracting young adults (age 25 to 34) and "early retirees" at about the same rate.

7. Provincial migration patterns by age, 1971 to 1996

It was noted above (Figure 3 and Tables 2 and 3) that there were substantive differences among the provinces <u>and</u> these differences appeared to be broadly consistant over time. In this section, the migration pattern of each province will be described in the order suggested by Figure 3. Again, please note that the description covers only internal migration from the 1976 census (and, therefore, migration from 1971) onwards. Throughout the following discussion the time periods refer to the time of migration not to the census dates.

7.1 British Columbia

British Columbia had the highest rates of RST out-migration (Table 2) and the highest rates of RST in-migration (Table 3). There was strong RST NET IN-migration in from 1976 to 1981 (forming part of Canada's rural 'population turnaround'). However, there was NET OUT-migration in the 1981 to 1986 period (again, as part of the 'turnaround of the turnaround' that was evident at the Canada level) (Figure A10 and Table A10 in Appendix A). After 1986, there was a return to RST NET IN-migration.

Within each age group, rates of out-migration increased for most age classes in each intercensal period from 1971 to 1991 and then declined somewhat in the 1991 to 1996 period (Figure C28 in Appendix C). In-migration rates were relatively low in the 1981 to 1986 period (paralleling the Canada-level observation) and have increased since then (Figure C29). As a result, NET migration was negative in the 1981 to 1986 period for most age groups (the exceptions were the groups between 45 and 69 years of age). However, in the period 1986 to 1996, NET IN-migration increased markedly. Interestingly, RST British Columbia had NET IN-migration for the 20 to 24 year age class between 1971 and 1981.

7.2 Alberta

Alberta had the second-highest rate of turnover in RST areas (Figure 3 and Tables 2 and 3). The province had RST NET IN-migration from 1971 to 1981 followed by a period of small NET OUT-migration from 1981 to 1991. Net migration turned positive again between 1991 and 1996.

Across the age groups, on average, RST areas in Alberta gained more persons than they lost from net migration for each age group from 25 to 64 years of age (Figure C27). These gains were particularly marked in the 1971 to 1981 period for the 25 to 44 years age classes and were due to a combination of relatively low out-migration (Figure C25) and relatively high in-migration (particularly between 1976 and 1981) (Figure C26). The net gain of any group over 40 years of age was small. Also, there was NET IN-migration for the 20 to 24 year age class in the 1976 to 1981 period.

7.3 Ontario

Ontario had the third-largest rate of turnover in RST areas (Figure 3 and Tables 2 and 3). RST Ontario had similar internal migration patterns to that of Canada as a whole (Figure A6 and Table A6). The exceptions were the 1976 to 1981 period (where strong RST out-migration resulted in NET OUT-migration), and the 1986 to 1991 period (where strong in-migration caused NET IN-migration to RST Ontario).

Across the age groups, migration patterns were similar to the Canadian pattern (Figures C16, C17 and C18), except that in-migration by 'early retirees' (those 55 to 64 years) was stronger in the later periods. This was particularly evident in the 1986 to 1991 period.

7.4 Saskatchewan and Manitoba

Saskatchewan and Manitoba were similar in that both, on average, experienced RST NET OUT-migration (Figures A7 and A8 and Tables A7 and A8). RST areas in Saskatchewan experienced the strongest NET OUT-migration of any province (in Figure 3, Saskatchewan is the province that is furthest below the diagonal).

Across the age groups, both Manitoba and Saskatchewan were dissimilar to the overall Canadian pattern with all age classes except those between 25 and 34 years and (in Manitoba, those between 55 to 64 years) having NET OUT-migration (Figures C21 and C24). Saskatchewan also had the highest out-migration rate of any province in the 20 to 24 year age class (Figure C22).

7.5 Quebec

RST Quebec had NET OUT-migration in every period, except for the 1991 to 1996 period. During this period higher RST retention caused a small RST NET IN-migration (Figure A5 and Table A5).

Across the age classes, there was NET OUT-migration for youth under 24 years of age and virtually a zero rate of net migration for all other age groups (Figure C15). In the 1991 to 1996 period, there were marginally higher rates of in-migration for young adults (25 to 34 years of age) (Figure C14) and lower rates of out-migration across all age classes (Figure C13). This resulted

in higher NET IN-migration to RST areas (or, in the case of youth and those aged 70 years and above, reduced NET OUT-migration).

7.6 The Maritime Provinces (Prince Edward Island, Nova Scotia and New Brunswick)

The Maritime Provinces had similar patterns of RST migration, characterised by low rates of RST out-migration, low rates of RST in-migration, and low rates of NET migration (Figures A2, A3 and A4 and Tables A2, A3 and A4). All three provinces had NET IN-migration between 1971 and 1976, principally due to slightly higher in-migration rates during this period. New Brunswick had low NET OUT-migration for the remaining intercensal periods. Apart from the 1986 to 1991 period, Nova Scotia had a small amount of NET IN-migration from 1976 to 1996. Prince Edward Island had NET OUT-migration between 1976 and 1991 before showing a small NET IN-migration between 1991 and 1996.

Across the age groups, in all three provinces, the migration pattern followed that of RST Canada as a whole. RST areas gained more than they lost from migration for each age class from 25 to 69 years of age. In general, for each group, the rates of in- and out-migration and the resulting net migration rates were relatively small (Figures C4 through C12).

7.7 Newfoundland and Labrador

RST areas in Newfoundland and Labrador had the lowest rate of RST in-migration among all provinces in all time periods (Figure 3 and Table 3). These rates were about one quarter of the in-migration rates in British Columbia. These persistent low rates of in-migration were the main reason for NET OUT-migration in each time period since 1971 (Figure A1 and Table A1).

Across the different age classes, the low rates of in-migration were evident in each age class (Figure C2). With just a few exceptions, RST Newfoundland and Labrador reported NET OUT-migration for every age class in every intercensal period (Figure C3).

8. Migration rates for Rural and Small Town Canada by selected characteristics

8.1 Education: rural brain drain or rural brain gain

It has already been seen that individuals aged 15 to 24 had high rates of out-migration from RST areas of Canada. A primary reason for this out-migration of youth is the fact that many must migrate in order to pursue higher education in an urban area. Education is important to migration not only because rural youth migrate to seek educational opportunity but also because there is a positive relationship between educational attainment (box 2) and migration rates. The rate of out-migration from RST areas is higher for each level of educational attainment (Figure 7).

Within each class of educational attainment, the rate of out-migration has remained very similar since 1971. The exception was the most recent period (1991 to 1996) where higher RST retention (i.e. lower out-migration rates) was evident in all groups of educational attainment.

Box 2 Definition of Educational Attainment

Less than grade 9:

Individuals aged 15 years and over who have not completed grade 9.

Grade 9 to 13:

Individuals without post-secondary education who have completed any year between grade(s) 9 and 13.

Post-secondary:

Individuals who possess a non-university certificate or trade certificate or who have some other post-secondary non-university education.

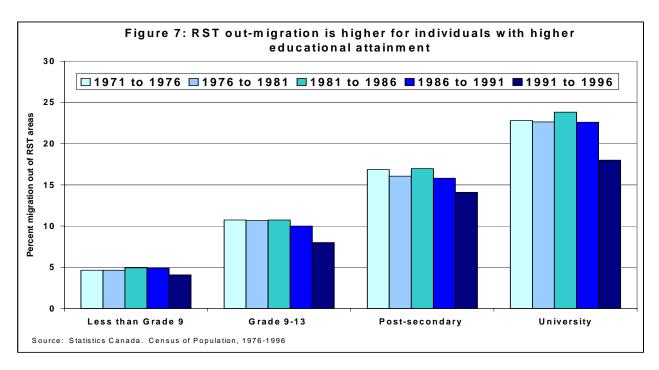

University:

Includes individuals who have completed university and possess a degree, those who were still attending university at the time of the census, and those who did not complete university.

Source: Statistics Canada, 1999.

Surprisingly, RST areas also show a higher in-migration rate for individuals with a higher educational attainment (Figure 8). Individuals with a university education had the largest rate of in-migration (3 times the rate for individuals with less than grade nine). Recall that the 1981 to 1986 period had an overall low rate of RST in-migration. This low rate of in-migration was apparent in each educational attainment group.

Thus, individuals with a higher level of educational attainment are more mobile. Both RST outmigration rates and RST in-migration rates are higher for individuals with a higher level of educational attainment. However, do RST areas gain or lose human capital due to migration. Is there a rural brain drain or a rural brain gain?

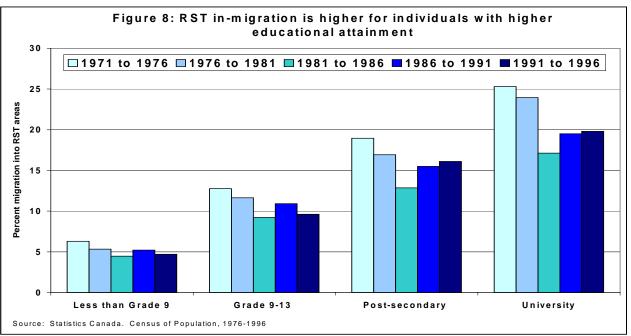

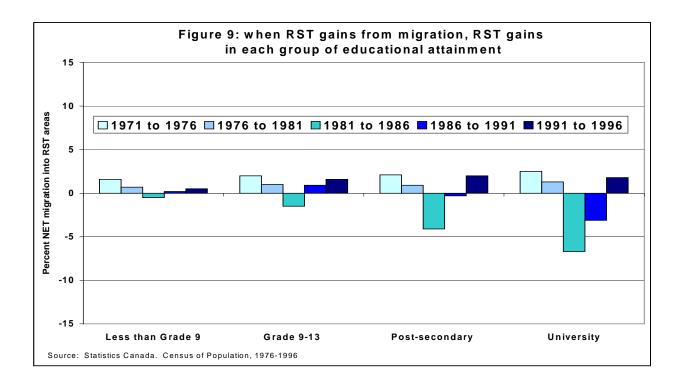

Figure 9 shows the NET migration rates for each educational attainment group. There was a small positive trend for each period from 1971 to 1996 with two exceptions. The first exception was the 1981 to 1986 period. Here, low in-migration rates caused RST NET OUT-migration in each education attainment group. Further, this NET OUT-migration rate was larger in the groups

with higher educational attainment. Second, the 1986 to 1991 period showed small net out-migration rates for the post-secondary and university groups.

In periods with overall RST NET IN-migration (i.e. the 1971 to 1981 period and the 1991 to 1996 period), there was also RST NET IN-migration in each group of educational attainment. RST areas were therefore competitive in attracting individuals with higher educational attainments. In this sense, there is a rural brain gain.

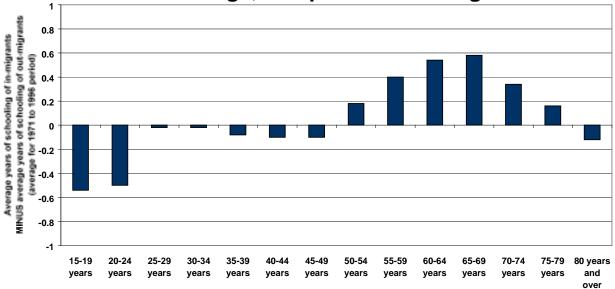

Interestingly, the average person who moves to RST areas has fewer years of schooling (12.4 years in 1991) compared to the average person who moves to a LUC (12.6 years of schooling). This observation held within each group of educational attainment⁴ (data not shown).

When years of schooling were broken down by age an interesting discrepancy was revealed. Each age group up to 50 years of age followed the overall pattern with RST in-migrants having more years of schooling (Figure 10). However, for age-classes between 50 years and 80 years of age the reverse pattern was apparent. The "early retirees" and older individuals migrating to RST areas had more years of schooling than RST out-migrants in the same age class.

18

⁴ Although by definition the individual had the same level of educational attainment, within the group we find that RST in-migrants required marginally fewer years of schooling to attain that level compared to RST out-migrants.

Migrants to RST areas aged 50 to 79 years of age have more years of schooling, on average, compared to out-migrants

Source: Statistics Canada. Census of Population, 1976-1996. Larger Urban Centres (LUC) refers to Census Metropolitan Areas and Census Agglomerations, which are urban cores of 10,000 or more plus neighbouring municipalities where more than 50 percent of the workforce commutes to the urban core. Rural and Small Town (RST) is thus the area outside the commuting zone of LUCs.

To summarise, the average out-migrant had more years of schooling than the average in-migrant. However, during periods of general net in-migration to RST areas there was NET IN-migration in each class of educational attainment. This observation was used to conclude that RST areas experienced a rural brain gain.

8.2 Labour force activity

Labour force activity (box 3) is important as the need to find employment is a major impetus for migration. The migration pattern of the employed and unemployed in RST areas provides two interconnected insights. First, it can give a sense of the economic conditions existing in rural areas. Second, it gives an indication of the level of human capital that is entering or leaving rural areas.

Box 3 Definition of employed, unemployed and "not in labour force"

Employed:

Individuals who, during the reference week of the survey, worked for pay or profit, or performed unpaid family work or who had a job but were not at work due to own illness or disability, personal or family responsibilities, labour dispute, vacation, or other reason. Those persons on layoff and those persons without work but who had a job to start in the future are not considered employed.

Unemployed:

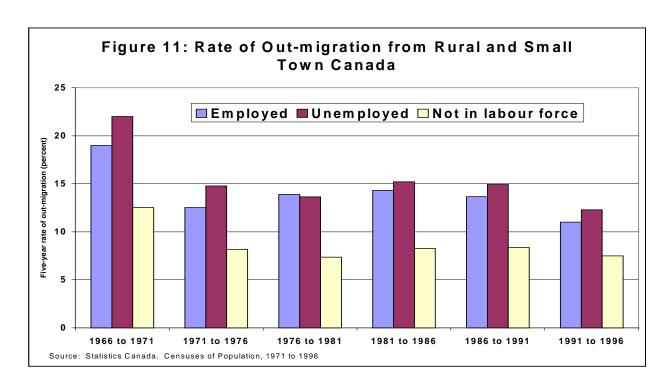

Individuals who, during the reference week of the survey, were without work, had actively looked for work in the past four weeks, and were available for work. Those persons on layoff or who had a new job to start in four weeks or less are considered unemployed.

"Not in Labour Force":

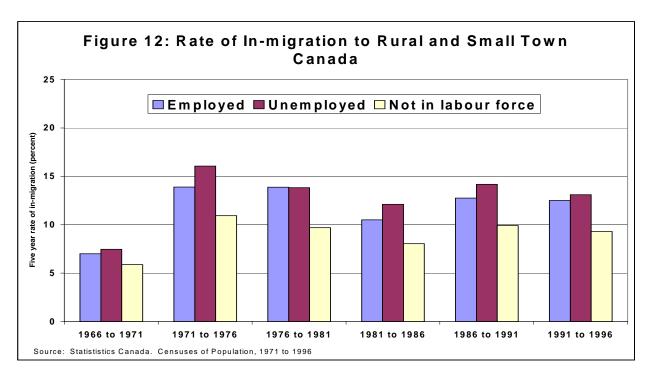

Civilian, non-institutionalized persons, 15 years and over who, during the reference week of the survey, were neither employed nor unemployed.

Source: Statistics Canada, 1999.

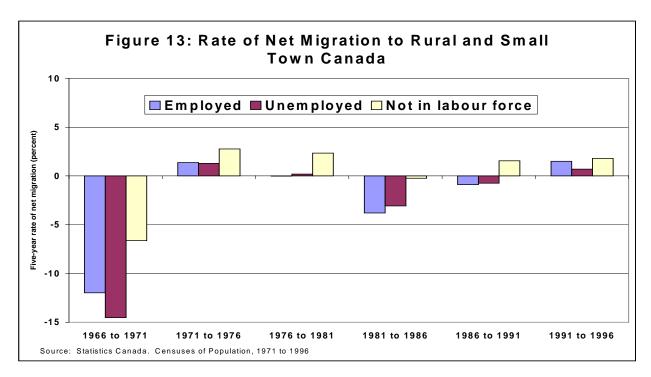

The pattern of out-migration of employed and unemployed individuals (Figure 11) showed the same pattern as the overall population (Figure 2) There were essentially stable rates of out-migration from 1971 to 1991 and slightly lower rates in the 1991 to 1996 period (Figure 11). In 5 out 6 inter-censal periods since 1966, unemployed persons had had a slightly higher propensity to leave RST areas.

The pattern of in-migration of employed and unemployed individuals (Figure 12) also showed the same pattern as that of the overall population (Figure 2). The lowest rates of in-migration after 1971 were recorded in the 1981 to 1986 period.

NET IN-migration of the employed and unemployed occurred in the 1971 to 1976 period, principally caused by higher in-migration. RST NET IN-migration also occurred in the 1991 to 1996, but this time as a result of lower out-migration (Figure 13). There was NET OUT-migration in the 1966 to 1971 period and 1981 to 1986 period. In both periods this was principally due to low in-migration.

The picture for individuals "not in the labour force" (e.g. students, retirees, etc.) was different in the sense that the "not in the labour force" persons had higher NET IN-migration (or lower NET OUT-migration) rates. Although the age distribution of these individuals was not specifically examined, it is likely that the low out-migration rates and relatively high in-migration rates of these individuals were mainly caused by the movement of retired persons.

9. Summary and conclusions

Patterns of migration into and out of rural and small town Canada were similar to the patterns reported in the USA. In the 1970s, there was a **turnaround** of the long-standing pattern of rural NET OUT-migration due to higher in-migration and lower out-migration. In the 1980s, the **turnaround of the turnaround** was evident. Here, the historical pattern of rural NET OUT-migration returned, caused by lower in-migration. Again in the early 1990s, there was a return to the pattern of the 1970s, namely, rural NET IN-migration, but this time due solely to higher RST retention (lower out-migration).

There were marked differences amongst the provinces in terms of RST migration. Moreover, these differences were broadly consistent through time. Ontario, Alberta and British Columbia had systematically higher rates of both RST in-migration and out-migration. These provinces experienced NET IN-migration into their RST areas. RST areas of Manitoba, Saskatchewan and, to a lesser extent, Quebec approached Ontario, Alberta and British Columbia in terms of their out-migration rate but had much lower in-migration rates. These provinces had NET OUT-migration from their RST areas. RST areas of Prince Edward Island, Nova Scotia and New Brunswick had systematically lower rates of both in-migration and out-migration and, in consequence, experienced relatively low levels of NET migration. RST areas of Newfoundland and Labrador experienced particularly low rates of in-migration and this was the main reason that this province displayed RST NET OUT-migration throughout the whole study period.

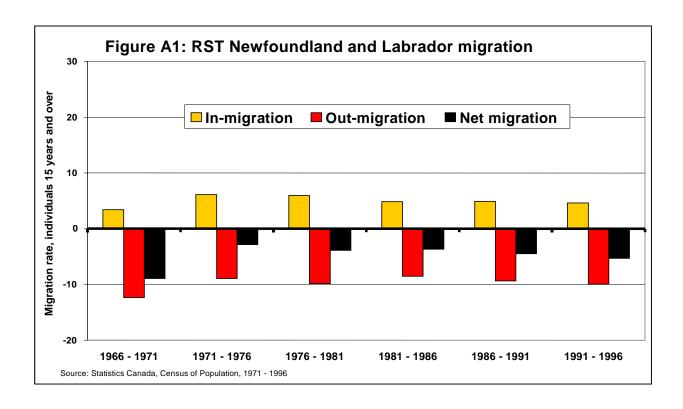

Young adults (those aged 20 to 29 years) were the most mobile during the study period. Those aged 20 to 24 years had the highest rates of RST out-migration, while those aged 25 to 29 years had the highest rates of RST in-migration. In terms of NET migration, RST areas were net losers of individuals aged 20 to 24 years but net gainers of individuals aged between 25 and 69 years. RST areas therefore appeared competitive in attracting migrants of all age classes from 25 to 69 years.

Overall, the average person leaving RST Canada had more years of schooling than the average person moving to RST Canada. Interestingly, in age groups between 50 years and 80 years of age, this pattern was reversed. For this group, the average person moving to RST Canada had more years of schooling. However, in periods of overall RST NET IN-migration, RST areas gained more individuals in each education class than it lost. In this sense RST areas experienced a brain gain, not a brain drain.

The migration patterns of the RST employed and unemployed tended to follow that of RST Canada as a whole. The unemployed in RST areas had a slightly higher rate of both out- and inmigration than did the employed. Individuals "not in the labour force" had a higher net inmigration rate (or lower net out-migration rate) compared to the employed and unemployed. This was probably due to the preponderence of retired individuals that are "not in the labour force".

Source: Statistics Canada. Census of Population, 1971 - 1996.

Note: Rural in-migration rate = urban-to-rural/(rural nonmovers + rural-to-urban)*100

Rural out-migration rate = rural-to-urban/(rural nonmovers + rural-to-urban)*100

Urban in-migration rate = rural-to-urban/(urban nonmovers + urban-to-rural)*100 Urban out-migration rate = urban-to-rural(urban nonmovers + urban-to-rural)*100

Figure B1 and Table B1 show that census rural⁵ lost population due to net migration during the 1966 to 1971 period. However, the gross rate of out-migration was consistent with subsequent periods (contrary to the conclusions from Figure 2 and Table 1) and the gross rate of in-migration was only somewhat lower than subsequent periods (contrary to Figure 2 and Table 1). To reconcile Figure B1 and Table B1 in Appendix B with the data in Figure 2 and Table 1, it should be noted that **census rural** has two components:

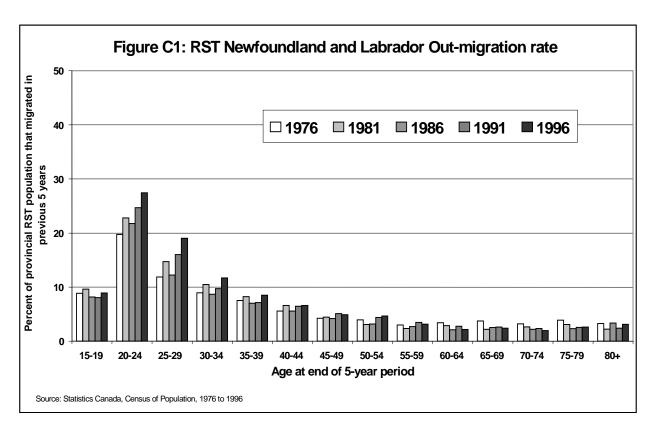

- Census rural outside CMA/CA boundaries; and
- Census rural inside CMA/CA boundaries, and **rural and small town** has two components:
- Census rural outside CMA/CA boundaries; and
- Small towns (with a population of 1,000 to 9,999)(outside CMA/CA boundaries).

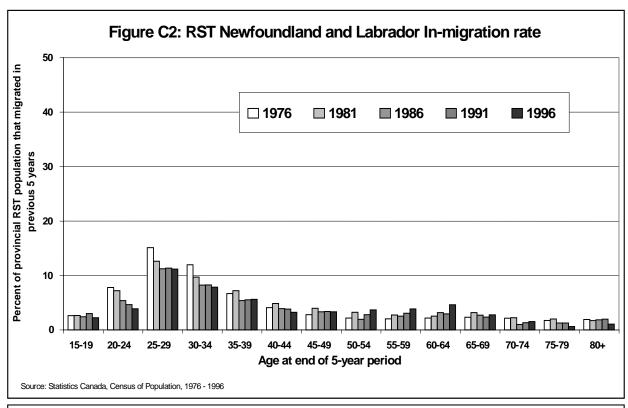

The migration patterns in **census rural** in the 1966 to 1971 period appear to be generally consistent with subsequent periods. This would seem to indicate that the divergent pattern in **rural and small town** migration patterns in the 1966 to 1971 period would be due to out-

⁵ "Census rural" refers to individuals living outside centres of 1,000 or more. One-third of the census rural population lives in the countryside within CMAs and Cas. For details, see du Plessis *et al.* (forthcoming).

migration from small towns (1,000 to 9,999) to the urban core of CMAs and CAs. Similarly, the observed RST net out-migration in the 1981 to 1986 period (Table 1 and Figure 2) may be reconciled with the census rural net in-migration (Table B1 and Figure B1) if there was considerable movement from census urban to census rural ("country estates") within CMAs and CAs during this period.
