## Canadian Technical Report of Fisheries and Aquatic Sciences 1907

## Canadian Technical Report of Fisheries and Aquatic Sciences

Technical reports contain scientific and technical information that contributes to existing knowledge but which is not normally appropriate for primary literature. Technical reports are directed primarily toward a worldwide audience and have an international distribution. No restriction is placed on subject matter and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Technical reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Number 1-456 in this series were issued as Technical Reports of the Fisheries Research Board of Canada. Numbers 457-714 were issued as Department of the Environment, Fisheries and Marine Service, Research and Development Directorate Technical Reports. Numbers 715-924 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Technical Reports. The current series name was changed with report number 925 .

Technical reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport technique canadien des sciences halieutiques et aquatiques

Les rapports techniques contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui ne sont pas normalement appropriés pour la publication dans un journal scientifique. Les rapports techniques sont destinés essentiellement à un public international et ils sont distribués à cet échelon. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports techniques peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports techniques sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annuel des publications scientifiques et techniques du Ministère.

Les numéros 1 à 456 de cette série ont été publiés à titre de rapports techniques de 1'Office des recherches sur les pêcheries du Canada. Les numéros 457 à 714 sont parus à titre de rapports techniques de la Direction générale de la recherche et du développement, Service des pêches et de la mer, ministère de l'Environnement. Les numéros 715 à 924 ont été publiés à titre de rapports techniques du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 925 .

Les rapports techniques sont produits à l'échelon régional mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

#### Abstract

Data gathered by the program to sample commercial mackerel catches are used to assess the status of this resource. These data are also analysed to improve our understanding of the dynamics of this species. During the sampling period, it was noted that the 1982 year-class was dominant in almost all samples. This year-class is characterized by a greater number of males and by smaller growth. Annual variations in some biological parameters are linked to the presence and development of this strong year-class. Results presented here may be used in more theoretical studies on the biology of this species.

## RÉSUMÉ

Les données recueillies dans le cadre du programme d'échantillonnage des captures commerciales de maquereau sont utilisées dans le processus d'évaluation de l'état de cette ressource. Ces données sont aussi analysées dans le but d'améliorer nos connaissances sur la dynamique de cette espèce. Lors de la période d'échantillonnage, il s'est avéré que la classe d'âge de 1982 était dominante dans presque tous les échantillons. Cette classe se caractérise par un plus grand nombre de mâles et par une croissance plus faible. Les variations annuelles de certains paramètres biologiques sont reliées à la présence et à l'évolution de cette forte classe d'âge. Les résultats qui sont présentés ici pourront être utilisés dans le cadre d'études plus théoriques sur la biologie de cette espèce.

## INTRODUCTION

Assessing the abundance of a resource is one of the fundamental phases of managing a fishery. The assessment involves not only quantifying a biomass but also predicting the reactions of this biomass to different management options (Hilborn and Walters 1992). Since it is not possible to determine the size of an entire stock, a representative sample must be taken. Under ICNAF, member countries were responsible for taking their own samples. Catch sampling techniques and frequency thus varied from one country to another. Sampling protocols were standardized in 1974; however, since the extension of its jurisdiction over fisheries in 1977, the frequency and quality of sampling by Canada have increased considerably (Stevenson 1983). A large number of species, including Atlantic Mackerel (Scomber scombrus L.), are now included in a vast sampling program along Canada's coasts.

Such a large-scale program is justified by the fact that data from the sampling of commercial catches may be used as base calculations for making assessments of abundance. These data are used for example in analyses of catches at age using the methods of Paloheimo or Doubleday (Hilborn and Walters 1992), of virtual populations (Gulland 1965; Pope 1972) or those based on the decrease in abundance such as the methods proposed by Leslie or DeLury (Ricker 1975). For mackerel, the main data taken from samples are fork length, weight, gonad weight and maturity stage, sex and age. Annual weight-length relationships are used to determine the weight of fish samples measured. Age is used to determine growth, age structure and the construction of age-length keys to be used to convert length frequency distributions to age frequency distributions. In mackerel, these frequencies are not currently being used in analyses of virtual populations due to the low fishing mortality rate and the lack of a valid index of stock size (Gregoire 1992a). Assessment of the mackerel in the Gulf of St Lawrence is done by the total egg production method (Grégoire 1992b). This method requires knowledge of the weight of gonads and of females ready to release eggs.

This study analyses biological data collected between 1983 and 1991 by the sampling program for commercial catches of mackerel. The main objective is to update these data and observe annual variations. The main results presented here may be used as the basis for future studies on more theoretical aspects of the biology of this species.

## MATERIALS AND METHODS

Mackerel were sampled at the wharf in the main landing ports. Sampling frequency depended on the intensity of fishing activity. The sampling protocol currently used requires that, if possible, a maximum of 250 fish chosen at random be measured to the nearest 0.5 cm . Of this number, two fish per 0.5 cm class were taken for laboratory analyses. Tables 1 and 2 show for each year the number of fish sampled per month, by Northwest Atlantic Fisheries Organization (NAFO) division (Figure 1) and subdivision. The number of fish caught and measured has decreased in recent years. This phenomenon is more pronounced in some areas, such as the Scotian Shelf for example, and requests have recently been presented for corrections to the sampling effort (Grégoire 1991, 1992b).

Age was determined by sagitta (otolith) readings, the use of which has been validated in mackerel (Steven 1952; MacKay 1967). Although the true birth date falls towards the end of June, it is considered by convention that this date is January 1. Thus, a fish born in a given year will be classified in Age Group One on the following January 1. For mackerel, it is relatively simple to determine age before age 12. Subsequently, readings become more difficult due to the curve of the margin and the narrowness of layers deposited. Poor calcification at the margin is also responsible for a decrease in the contrast observed between the hyaline and opaque layers (Dery 1988). Readings were taken at more than one location around the otolith to avoid considering growth anomalies as true annuli. Particular attention was paid to the rostrum since the spacing between the hyaline zones is greatest there. Delayed deposit was seen in fish from the age of three or four. A delay was also observed in fish of all ages from the east coast of Newfoundland.

Otolith readings were also used to obtain information on life-span and variations in recruitment, as well as on growth, which was estimated using the von Bertalanffy model (Ricker 1975) for length and weight at age. The parameters of the model were defined using the SAS NLIN procedure (SAS/STAT 1990), which uses the DUD iteration method. The growth model was calculated using all data and the Fisher test (Zar 1974) was used on residues to determine whether there were any differences in growth between males and females. The instantaneous growth rate for the 1982 to 1986 year-classes was calculated on the basis of linear relationships between the weight and age logarithms. These classes were chosen because of the presence of the earlier age groups for which growth is rapid and the desire to make calculations using at least five values to prevent biased results. A year-class is defined here as the birth year of a fish and is calculated as being the year of capture less the age of the fish. The mean lengths and weights for each age group were compared on an annual basis and between the dominant year-classes by a variance analysis (Kirk 1982). The instantaneous growth rate and the proportions of immature fish by age and by length class were calculated and compared between the most recent classes. Weight-length relationships were calculated and expressed logarithmically for each year. Equality of slopes and ordinates at the origin of relationships were compared (Zar 1974) with a view to checking whether it was possible to use only one relationship for all data.

Sex was determined by visual examination of gonads, since sex in mackerel cannot be determined, as in some species, on the basis of external morphological criteria. Once each specimen was thawed, the gonads were carefully removed and weighed. Equality in the sex ratio was checked for each age group with a chi-square test (Zar 1974). Fish over 12 years old were not included in these analyses due to uncertainty related to age determination. The hypothesis that each age group came from the same statistical population was verified by the chi-square heterogeneity test (Zar 1974).

The degree of gonad maturity was established on the basis of criteria proposed by Parrish and Saville (1965) for herring (Clupea harengus harengus L.). These criteria were adapted for mackerel and eight stages established. The fifth corresponded to fish about to release eggs. It is at this stage that gonads reach their maximum size. The colour and relative size of male and female gonads in the abdominal cavity as well as the form, colour and size of ovules were the main criteria used to determine sexual maturity.

The mean values calculated for length and weight of fish, weight of gonads and the gonadosomatic index are presented for each stage of maturity. The purpose of this is to describe the variation patterns in these variables and determine which might enable us to best describe each stage of maturity without using the Parrish and Saville (1965) scale. The gonado-somatic index is also used to describe spawning seasons. Size at maturity as well as the degree of maturation between males and females were calculated for NAFO divisions where data is sufficient.

Length frequencies recorded annually were first sorted by month in order to present possible variations in size linked to seasonal migration of mackerel. Frequencies were also classified by type of gear (net, fixed or trap, line and seine) to describe and compare the main sizes caught by each.

## RESULTS

## SEX RATIO AND AGE STRUCTURE

The hypothesis of equality in the sex ratio was rejected on several occasions for some age groups (Table 3). In most cases, these groups were from the 1982 year-class when a larger number of males were observed. The presence of these significant differences in the sex ratio did not justify the use of the chi-square heterogeneity test. For other age groups where the equality hypothesis was rejected, there were almost as many cases where each of the sexes dominates alternately.

Age distributions of samples analysed in the laboratory were characterized by the dominance of the 1982 year-class (Figure 2). This class became the largest in the fishery from the age of two on. Despite the presence of other major classes, those of 1987 and 1988, the 1982 year-class was still the dominant year-class in samples in 1991. The presence and development over the years of these major classes also enabled us to compare and validate age readings. For example in 1986, summer growth in the 1982 class, then in Age Group 4, was very slow. The corresponding opaque zone, i.e. the fifth since birth, was almost invisible. A similar phenomenon was observed by MacKay (1979) for the 1959 year-class. Detection of this anomaly was only possible through annual monitoring, which would have led to an underestimation of true age and biasing of growth estimates.

Several modes were found in the size structure of fish aged in the laboratory, each of which corresponded to a year-class (Figure 3). When one class dominates significantly, like that of 1982 between 1985 and 1988, only one main mode was observed. Conversely, a multimodal distribution reflected the presence of several year-classes. Overlapping of modes encountered towards the end of distributions was due to a decline in growth encountered in older fish.

## LENGTH AND WEIGHT AT AGE

Growth in mackerel, expressed in terms of length or weight at age, was very rapid during the early years (Figures 4 to 9). Towards age four, an annual difference in size was observed between males and females. In all cases, females had a length and weight at age significantly greater than males (Fisher Test, $\mathrm{P}<0.0001$ ). Brody growth coefficients calculated for both sexes decreased gradually between 1983 and 1988 (Tables 4 and 5). During this period, the 1982 yearclass was increasingly found in both the fishery and in samples. These variations in values of Brody coefficients resulted in a decrease and an increase in the curve of corresponding growth relationships (Figures 5, 6, 8 and 9). The higher the Brody coefficient, the faster the decrease in the exponential growth which appeared at a certain point. In other words, this coefficient does not necessarily give an adequate indication of true growth. Moreover, since the growth relationships expressed by the von Bertalanffy model varied widely from year to year, a single model for each sex based on all data would not be appropriate, and growth in the population should be expressed using the most recent model.

Lengths and weights at age showed significant annual differences (Figures 10 and 11). No particular pattern was observed in annual changes in mean length at age. However, for certain years, a decrease then an increase were observed in mean weight at age for age groups 4 to 6 . The lowest mean weight values for these ages were always found in the 1982 year-class.

## WEIGHT/LENGTH RELATIONSHIPS

Annual weight-length relationships lined up exponentially (Figure 12). A logarithmic transformation was used to express these relationships, for males and females, using a linear regression (Table 6). The relationships were all significant ( $\mathrm{P}<0.0001$ ) and in most cases, there was no difference between the two sexes in weight changes based on length (Table 6). There is thus no justification for making a distinction between the two sexes when calculating ratios. The slopes of annual relationships, males and females combined, were all significantly different ( $\mathrm{F}=143.77, \mathrm{P}<0.0001$ ) (Figure 13). The weight of samples taken at the wharf can thus not be calculated based on a relationship including data for all years. By convention, the weight of samples for a given year should be calculated based on the previous year's ratio then adjusted once the biological data for the current year were analysed. The relationship must accordingly be calculated annually.

During this study, visual examination of weight-length relationships enabled us to detect any major errors made in base files when collecting or entering data.

## MATURITY AND WEIGHT OF GONADS

The mean length by stage of maturity increased rapidly from the first stage to Stage 3 and then stabilized (Figure 14). This pattern, which is similar from one year to another, is linked to the rapid growth in the early years. Although there were not enough Stage 1 fish to draw conclusions, the size of immature Stage 2 fish in 1983 was larger than 300 mm . For subsequent years, it was around 250 mm , rising in 1991 to a value greater than 300 mm . A similar change was also observed in the case of mean weight (Figure 15). Thus at the time when the 1982 yearclass was dominant, the size and weight of immature fish were smaller.

The mean weight of male and female gonads increased from Stage 1 to Stage 5 (Figures 16 and 17). It subsequently decreased because of the onset of spawning. Variances in mean values were higher for Stages 4 to 6 . As opposed to the earlier stages, these variances were due to the presence of fish with a wider range of sizes. These high variances may also have been due to a difference in the length of each stage and possibly to errors in classification. Variances were much narrower in the case of the gonado-somatic index (Figures 18 and 19). The profile of variations in the index could be used to confirm the degree of maturity of a gonad.

At the beginning of each sampling season, values of the gonado-somatic index in males and females were greater than $10 \%$ (Figures 20 and 21). These values, which corresponded to Maturity Stage 5 (Figures 18 and 19), then decreased rapidly. This decrease in the index was due to the onset of spawning activities and variations observed may have corresponded to regional differences in spawning schedules. Spawning was basically over by Day 210, i.e. July 29, and the value of the index remained low until the end of the sampling season. Sampling carried out towards the end of the winter along the American coast and in early spring south of Nova Scotia might enable us to complete the ascending part of the cycle.

The profile of daily changes in the gonado-somatic index in 1983 was very different from that of other years (Figures 20 and 21). An attentive examination of the data base for 1983 enabled us to detect errors in the weight of gonads of fish sampled in Divisions 3K and 3L on the east coast of Newfoundland. The profile of values of the gonado-somatic index calculated using these data suggest a delay or cessation in the spawning process. This seems to be indicated by the high, stable values observed in the index towards the end of the season. Even though fish may be found late in the season with gonads of a certain size, as in the Magdalen Islands in September 1992 (Carole Turbide, pers. comm.), it would be unwise to suggest that such a striking delay in spawning really occurred in 1983.

In Stage 5 fish, i.e. those ready to spawn, it was often found that the median size of males was smaller than that of females (Figure 22). This was observed in 1983, 1984, 1987, 1988, 1989 and 1990 and is also in line with differences observed during these same years in growth between males and females.

The median length of Stage 5 male and female gonads decreased gradually from 1983 to 1988, i.e. during the passage of the 1982 year-class, increased until 1990 and then decreased once again
in 1991 with the arrival of another probably significant class, that of 1988. In addition, the small number of observations made it impossible to present adequate conclusions on the speed of maturation between the sexes (Figures 23, 24 and 25).

## PRELIMINARY DESCRIPTION OF YEAR-CLASSES

In the samples taken between 1983 and 1991, it was possible to find fish from year-classes as old as those of 1966 and 1967, that is, fish aged 16 and 17 at the time they were caught. The representativeness of these older year-classes was often biased because it has proved difficult to determine the age of fish older than 12 years. Since the first samples dated from 1983, year-old fish taken during this year were from the 1982 year-class (Tables 7 and 8 ).

Mean lengths at age (Table 7) and mean weights at age (Table 8) were, in most cases, significatively different from one year-class to another. With the exception of ages four and five, no trend in the profile of mean length variations was observed. In the case of these last two age groups, mean length decreased to the 1982 class and then increased. This profile is more pronounced in the case of mean weight at age. For Age Group 4, mean weight by class decreased from the 1979 year-class to that of 1982. It then increased until the 1986 class and declined again for that of 1987. For Age Group 5, mean weight decreased from the 1978 yearclass to that of 1982 and then increased to the 1986 year-class. These variations between yearclasses explain the variations in weight or length already observed in figures 10 and 11. In fact, the same fish were compared on the basis of year of capture or year-class.

Variations in length or weight of the main year-classes in a given year fluctuated widely (Figures 26 and 27). A decrease in length or weight could even be observed in the course of a year. The sampling may be responsible for this. It was carried out at the same time and at different locations and at the same location at different times. For example, a reduction in weight might be due to a reduction in the weight of gonads at spawning. Moreover, samples were taken from catches using different types of gear each with its own particular selectivity.

The linear relationships between logarithms of weight and age were all significant ( $\mathrm{P}<0.001$ ) . Instantaneous growth rates, i.e. the slopes of each linear relationship, increased from the 1982 year-class to that of 1986 (Figure 28). Growth rates were almost significantly different from one another ( $\mathrm{F}=2.55, \mathrm{P}<0.0642$ ). The covariance analysis was also significant ( $\mathrm{F}=2.81, \mathrm{P}<$ 0.0435 ). The number of observations decreased from one class to another and growth rates could again be compared with the addition of new annual values. Other growth models could also be used.

The mean lengths and weights of mature fish (Stage 5) in certain age groups were, in the case of 1982 year-class, smaller compared to the 1980, 1981, and 1983 to 1989 classes (Table 9). In all these classes, there does not appear to be a relationship between the proportion of immature or mature fish and age (Table 10). Conversely, it would appear that there is a relationship
between the proportion of immature and size (Shaded areas, Table 11). For the 1982 year-class, the degree of maturity was more advanced in the smaller size fish.

## LENGTH FREQUENCIES

Annual length frequency distributions recorded since 1984 show two different patterns. The first, found in 1984, 1990 and 1991 was characterized by multimodal distribution (Figure 29). The second pattern, found in other years, instead showed a unimodal distribution. Based on the characteristics observed in Figure 3, the form of length frequency distributions appears to be caused by the presence of one or more relatively dominant year-classes.

From May to June, there is a movement of the main modes towards smaller sizes (Figures 30 to 37). This observation, which was more pronounced in some years than in others, was noted by Hunt (1975) and MacKay (1979). Larger fish are thus caught early and late in the season. This may be due to the fact that mackerel movements are linked to size. The larger fish enter the Gulf first in the spring and leave it last in the fall.

Length frequency distributions, once classified by type of gear, were also characterized by the presence of one or more modes (Figure 38). When the distribution of frequencies for a given year showed only one mode, for example, the distributions encountered for each type of gear for this year showed a unimodal aspect. However, nets caught more larger fish. When there was more than one major mode, certain categories of gear such as fixed gear and lines caught smaller fish than others. The selectivity of fishing gear is also linked to different fishing activities and the migratory aspect of mackerel. For example, purse seines are used in the fall on the west coast of Newfoundland. At that time of year, this region is mainly characterized by the presence of large fish en route to the outer Gulf. The sizes found will not be representative of the range of sizes that can be caught with this type of gear.

## DISCUSSION

The Atlantic Mackerel population in the Gulf of St Lawrence is characterized by the more or less regular appearance of a dominant year-class (1959, 1967, 1974, 1982). The strength of such a class may persist over several years. For example, that of 1959 was still being felt in 1973 (MacKay 1979). Dominance is such that the class may alone represent the majority of commercial catches over a certain number of years (Grégoire 1992b). What is observed annually in the population is closely related to the presence of such a class. During this study, it was found that variations in the sex ratio, mean length and mean weight at age, length frequency distributions and the selectivity of fishing gear were closely related to the presence and development of the 1982 year-class. Fish of this class showed lower growth at age. This observation was also noted by Overholtz (1989) for samples taken during research cruises, sport and commercial fishing (Polish) along the U.S. coast. The decline in growth was also seen in otoliths. The radius of the first annulus calculated for a certain number of otoliths from this
class shows a smaller mean value than that calculated for other classes ( F . Grégoire, unpublished data).

Maturity of a dominant year-class should be delayed because of the decline in growth. For example, the first fish in the 1959 year-class to mature did so only when they were three years old. Moreover, it was only at age five that all fish in this year-class and that of 1967 were mature (MacKay 1979). A relationship between density, growth and maturity was observed by Agnalt (1989) for North Sea mackerel. An increase in growth, together with an increase in fishing effort due to the arrival of modern seiners and a reduction in the biomass were responsible for this decrease in age at maturity. Length at maturity nevertheless remained the same. Maturity thus appears to be independent of age but dependent on size. The present data yield no such clear conclusions on the relationship between the age, growth and maturity of the 1982 year-class. The classes that preceded were represented only by older age groups, and it is impossible to assign them a median age or median size at maturity. For year-classes after 1982, the number of age groups decreased from one class to another and it is then difficult to make comparisons. Maturity could even be determined by a complex interaction between size and age. This study of maturity could be supplemented by the addition and analysis of new data from the annual sampling program.

## ACKNOWLEDGEMENTS

The author wishes to express his heartfelt gratitude to all the samplers who have participated in the collection of mackerel samples over the years. Thanks are also due to Dr Martin Castonguay and to Alain Fréchet and Daniel Gauthier for reviewing this report.
