## Note of appreciation

Canada owes the success of its statistical system to a long-standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.

#### Abstract

In order to provide a holographic or complete picture of low income, Statistics Canada implements an approach that uses three complementary low income lines: the Low Income Cutoffs (LICOs), the Low Income Measures (LIMs) and the Market Basket Measure (MBM). While the first two lines were developed by Statistics Canada, the MBM is based on concepts developed by Human Resources and Skill Development Canada. Though these measures differ from one another, they give a generally consistent picture of low income status over time. None of these measures is the best. Each contributes its own perspective and its own strengths to the study of low income, so that cumulatively, the three provide a better understanding of the phenomenon of low income as a whole. These measures are not measures of poverty, but strictly measures of low income.

The LICOs are based on the relationship between the incomes and the consumption patterns of Canadian households as observed in 1992. The LICOs have been very widely used in Canada since the 1970s. On the other hand, the LIM is based solely on the distribution of household income across the Canadian population and is intended as a reference for international comparisons. Statistics Canada has been producing the LIMs since 1991 and they are aligned with latest international standard. Finally, the MBM defines low income in relation to the cost of a predefined set of goods and services. The price of this "basket" of goods and services takes regional differences in the cost of living into account.

This publication incorporates a detailed description of the methods used to arrive at each of these measurements. It also explains how base years are defined and how LICOs are updated using the Consumer Price Index. Because the LICOs only depend on the annual Consumer Price Index, they can be produced as soon as the CPI is available (January following the reference year). The LIMs and the MBM depend on other survey products that are available much later. Consequently, they can only be produced 16 to 18 months after the end of the reference year. For these reasons, this report contains LICOs up to 2011, but LIMs and MBM up to 2010 only.

## Introduction

Statistics Canada has a long history of publishing data on the low income of Canadians. The low income cut-offs (LICOs) were first published in 1967 as part of the 1961 Census monograph series and are by far Statistics Canada's most established and widely recognized approach to estimating low income cut-offs. LICOs are income thresholds below which families devote a larger share of income to the necessities of food, shelter and clothing than the average family would.

Following the practice of many international organizations, Statistics Canada began to publish before- and after-tax low income measures (LIMs) in 1991. LIMs are particularly convenient for making international comparisons, since estimating the cut-offs requires only data on household incomes within a country. As such, they require no adjustments using exchange rates or purchasing power parity indexes as would be necessary to make meaningful comparisons of absolute levels of income between countries.

The Market Basket Measure (MBM) was developed by Human Resources Development Canada (HRSDC) to represent a standard of living that is a compromise between subsistence and social inclusion that reflects differences in living costs across the country (Hatfield, Pyper and Gustajtis 2010). The thresholds are produced for a reference family of two adults and two children for all sizes of area of residence in each province and for several cities. While HRSDC is responsible for defining the components of the basket and the related concepts, Statistics Canada is responsible for the costing of the components and producing low income statistics.

Media, researchers and policy-makers interested in measures of low income are typically concerned with the extent to which individuals in the population are living in poverty. Unfortunately, defining poverty is far from straightforward. The underlying difficulty is that poverty is a question of social consensus, defined for a given point in time and in the context of a given country. Decisions on what defines poverty are subjective and ultimately arbitrary (Statistics Canada, 1999 and Skuterud et al., 2004). Given this, Statistics Canada has always referred to the low income lines as indicators of the extent to which some Canadians are less well-off than others based solely on income and, as such, are low income and not poverty measures.

Other statistical organizations are also sensitive to the use of the word 'poverty'. Eurostat refers to its measure (similar to the LIM) as an 'at risk of poverty' measure. In the United States, where an official poverty measure exists, the poverty rates are qualified as being calculated according to a specified definition, allowing that other measures are possible.

The purpose of this document is to provide the dollar cut-offs used to define the low income population. Low income status can be determined using family or household income. The family concept used is the economic family, that is, all persons living in the same dwelling and related by blood, marriage, common-law relationship or adoption. A household is defined as a person or group of persons residing in a dwelling.

## Historical Revision of 2006 to 2009

This release is accompanied by an historical revision for 2006 to 2009. Beginning in 2006, survey estimates from the Survey of Labour and Income Dynamics are produced on the basis of population counts based on the 2006 Census of Population, instead of the 2001 Census. As a consequence, the Low Income Measures (LIMs), low income rates and low income gap ratios, as well as all estimates in the CANSIM 202 series were revised for that period. While the actual levels of the estimates have changed in many situations, broadly speaking, the trends shown by the data remain very similar. For more information about the impact of this revision, please refer to the "What's new" section of the 2010 SLID Survey Overview (Statistics Canada, 2012). Note that survey estimates prior to 2006 were not revised.

## Low income cut-offs

## What are the LICOs?

The low income cut-offs (LICOs) are income thresholds below which a family will likely devote a larger share of its income on the necessities of food, shelter and clothing than the average family. The approach is essentially to estimate an income threshold at which families are expected to spend 20 percentage points more than the average family on food, shelter and clothing. ${ }^{1}$ The first set of published LICOs used the 1959 Family Expenditure Survey to estimate five different cutoffs varying between families of size one to five. These thresholds were then compared to family income from Statistics Canada's major income survey, the Survey of Consumer Finances (SCF) ${ }^{2}$, to produce low income rates.

Today, Statistics Canada continues to use precisely this approach to construct LICOs, with the exception that cut-offs now vary by 7 family sizes and 5 different populations of the area of residence. ${ }^{3}$ This additional variability is intended to capture differences in the cost of living amongst community sizes. ${ }^{4}$

## How are LICOs calculated?

As mentioned previously, a LICO is an income threshold below which a family will likely devote a larger share of its income to the necessities of food, shelter and clothing than an average family would. According to the most recent base for LICOs, the 1992 Family Expenditures Survey, the average family spent $43 \%$ of its after-tax income on food, shelter and clothing. Figure 1 shows the calculation of a LICO using the example of a family of four living in a community with a population between 30,000 and 99,999. The 63\% line represents the average proportion of after-tax income that all families (regardless of size) spent on food, shelter and clothing in 1992 (i.e. 43\%) plus the

[^0]20 percentage point margin. The dots on the chart show the actual observed proportion of income spent by four-person families in that community size on necessities, according to the 1992 Family Expenditure Survey. A regression line is fitted to this distribution and the intersection of that curve and the $63 \%$ line gives the LICO—in this case, $\$ 21,359 .{ }^{5} 67$

This process is carried out for seven family sizes and five community sizes and results in a table of 35 cut-offs. This operation is done twice: once for before-tax cut-offs, once for after-tax cut-offs.

Figure 1

## Calculation of an after-tax LICO

Source: Survey of Family Expenditures (Famex), 1992.

## Rebasing and indexing the LICOs

Over time, Canadian families have spent a smaller percentage of their income on the necessities of food, shelter and clothing. This relationship between families' income and spending is associated with a specific point in time, i.e. the year of the expenditure survey used to derive the cut-offs. That particular year is referred to as the base year for the set of cut-offs. In order to account for changing spending patterns, Statistics Canada has in the past recalculated new LICOs after each subsequent Family Expenditure Survey. This process is referred to as rebasing and includes recalculating new LICOs using the method described in "How are low income cut-

[^1]offs calculated?" and the new spending data. In addition to the 1992 base, LICOs have also been based on the 1986, 1978, 1969 and 1959 Family Expenditure Surveys; although cut-offs based on 1992 are the most commonly used and are available for the income reference years from 1976 onwards. ${ }^{8}$

After having calculated LICOs in the base year, cut-offs for other years are obtained by applying the corresponding Consumer Price Index (CPI) inflation rate to the cut-offs from the base year the process of indexing the LICOs. The CPI are provided at the end of this document. For example, continuing with the 1992 after-tax LICO for a family of four living in a community with a population between 30,000 and 99,999; to calculate the corresponding LICO for 2011, the Consumer Price Index is used as follows:
$\mathrm{LICO}_{2011}=\mathrm{LICO}_{1992} \times \mathrm{CPI}_{2011} / \mathrm{CPI}_{1992}=21,359 \times 119.9 / 84.0=30,487$

Thus for 2011, the 1992 based after-tax LICO for a family of four living in a community with a population between 30,000 and 99,999 is $\$ 30,487$, expressed in current dollars.

Because the LICOs only depend on the annual Consumer Price Index, they can be produced as soon as the CPI is available, that is January following the reference year.

Note that using the CPI to update the cut-offs takes inflation into account, but does not reflect any changes that might occur over time in the average spending on necessities.

## Use of after-tax and before-tax LICOs

The average proportion of income that families spend on food, shelter and clothing, which figures prominently in the low income cut-offs, is undoubtedly a useful gauge of economic well-being no matter which income concept is used. The choice of after-tax income, total income or market income depends on whether one wants to take into account the added spending power that a family gets from receiving government transfers or its reduced spending power after paying taxes.

Statistics Canada produces two sets of low income cut-offs and their corresponding rates-those based on total income (i.e., income including government transfers, before the deduction of income taxes) and those based on after-tax income. Derivation of before-tax versus after-tax low income cut-offs are each done independently. There is no simple relationship, such as the average amount of taxes payable, to distinguish the two types of cut-offs.

Although both sets of low income cut-offs and rates continue to be available, Statistics Canada prefers the use of the after-tax measure.

The choice to highlight after-tax rates was made for two main reasons. First, income taxes and transfers are essentially two methods of income redistribution. The before-tax rates only partly reflect the entire redistributive impact of Canada's tax/transfer system because they include the effect of transfers but not the effect of income taxes. Second, since the purchase of necessities is made with after-tax dollars, it is logical to use people's after-tax income to draw conclusions about their overall economic well-being.

[^2]
## Differences in after-tax and before-tax rates

The number of people falling below the cut-offs has been consistently lower on an after-tax basis than on a before-tax basis. This result may appear inconsistent at first glance, since incomes after tax cannot be any higher than they are before tax, considering that all transfers, including refundable tax credits, are included in the definition of "before-tax" total income. However, with a relative measure of low income such as the LICO, this result is to be expected with any income tax system which, by and large, taxes those with more income at a higher rate than those with less. These "progressive" tax rates compress the distribution of income. Therefore, some families in low income before taking taxes into account are relatively better off and not in low income on an after-tax basis.

## Low income measures

## What is the LIM?

For the purpose of making international comparisons, the LIM is the most commonly used low income measure. The use of the low income measure (LIM) was suggested in 1989 in a discussion paper written by Wolfson, Evans, and the OECD ${ }^{9}$ which discussed their concerns about the LICOs. In simple terms, the LIM is a fixed percentage (50\%) of median adjusted household ${ }^{10}$ income, where "adjusted" indicates that household needs are taken into account. Adjustment for household sizes reflects the fact that a household's needs increase as the number of members increases. Most would agree that a household of six has greater needs than a household of two, although these needs are not necessarily three times as costly.

The LIMs are calculated three times; with market income, before-tax income, and after-tax income using the Survey of Labour and Income Dynamics (SLID). They do not require updating using an inflation index because they are calculated using an annual survey of household income. Unlike the low income cut-offs, which are derived from an expenditure survey and then compared to an income survey, the LIMs are both derived and applied using a single income survey.

## How is the LIM calculated?

In order to calculate the LIMs ${ }^{11}$, first calculate "equivalent household income" for each household by dividing household income by its "adjusted size", that is the square root of the number of persons in the household. Next, assign this adjusted household income to each individual in the population. Then determine the median of this "equivalent household income" over the population of individuals, that is the amount where half of all individuals will be above it and half below. The LIM for a household of one person is $50 \%$ of this median "equivalent household income", and the LIMs for other sizes of households are equal to this value multiplied by their "equivalent household size".

[^3]As described in the above section on the Historical Revision, the LIMs for 2006 to 2009 have been recalculated (Table A).

Table A
Low income measures, for household size of four persons (current dollars)

|  | Market income |  | Before tax |  | After tax |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | Pre-revision | Post-revision | Pre-revision | Post-revision | Pre-revision | Post-revision |
| 2006 | 34,170 | 34,232 | 38,726 | 38,806 | 33,470 | 33,578 |
| 2007 | 35,722 | 35,906 | 40,506 | 40,630 | 35,404 | 35,512 |
| 2008 | 37,644 | 37,736 | 42,378 | 42,596 | 37,164 | 37,336 |
| 2009 | 37,068 | 37,300 | 42,256 | 42,500 | 37,360 | 37,562 |

## Market Basket Measure (2008 base)

## What is the MBM?

The MBM is based on the cost of a specific basket of goods and services representing a modest, basic standard of living. It includes the costs of food, clothing, footwear, transportation, shelter and other expenses for a reference family of two adults aged 25-49 and two children (aged 9 and 13). It provides thresholds for a finer geographic level than the LICO, allowing, for example, different costs for rural areas in the different provinces. These thresholds are compared to disposable income of families to determine low income status. Disposable income is defined as the sum remaining after deducting the following from total family income: total income taxes paid; the personal portion of payroll taxes; other mandatory payroll deductions such as contributions to employer-sponsored pension plans, supplementary health plans, and union dues; child support and alimony payments made to another family; out-of-pocket spending on child care; and noninsured but medically prescribed health-related expenses such as dental and vision care, prescription drugs, and aids for persons with disabilities.

The MBM and the MBM disposable income were designed by a working group of Federal, Provincial and Territorial officials, led by HRSDC between 1997 and 1999 (Hatfield 2002; Michaud, Cotton and Bishop 2004). During 2009 and early 2010, it underwent a comprehensive review of both content and methodology (Hatfield, Pyper and Gustajtis 2010). The consultation process, led by HRSDC, involved officials from Provincial and Territorial governments, other federal governments and agencies including Statistics Canada and a panel of experts in low income measurement. This review process led to a rebased series of thresholds (MBM 2008 base), revised historically to 2000, the beginning of the MBM time series. ${ }^{12}$

[^4]
## How are MBM thresholds calculated?

The MBM thresholds are calculated as the cost of purchasing the following items:

- A nutritious diet as specified in the 2008 National Nutritious Food Basket (Health Canada 2009).
- A basket of clothing and footwear required by a family of two adults and two children
- Shelter cost as the median cost of a two- or three-bedroom units including electricity, heat, water and appliances
- Transportation costs, using public transit where available or costs associated with owning and operating a modest vehicle where public transit is not available.
- Other necessary goods and services.

## Low income rate and low income gap ratio

To determine whether a person is in low income, the appropriate low income line (LIL) is compared to the income of the person's family ${ }^{13}$ (or household) ${ }^{14}$. If their income is below the cut-off, the individual is considered to be in low income. In other words, "persons in low income" should be interpreted as persons who are part of low income families (or households), including persons living alone whose income is below the cut-off. Similarly, "children in low income" means "children who are living in low income families (or households)". Overall, the low income rate for persons can then be calculated as the number of persons in low income divided by the total population. The same can be done for various sub-groups of the population; for example, low income rates by age, sex, or province.

After having determined that an individual is in low income, the low income gap ratio can be analysed by using the amount that the person's family (or household) income falls short of the relevant low income cut-off, expressed as a percentage of the relevant low income cut-off ${ }^{15}$. For example, an individual living in a family (or household) with an income of $\$ 15,000$ and a low income cut-off of $\$ 20,000$ would have a low income gap of $\$ 5,000$. In percentage terms, the "gap ratio" would be $25 \% .{ }^{16}$ The average (or median) gap ratio for a given population is the average (or median) of these values as calculated for each person.

As described in the above section on the Historical Revision, the low income rates and low income gap ratios for 2006 to 2009 have been recalculated for all low income lines.

## Notes:

1. To convert to other family sizes, divide these values by 2 (the square root of the reference family size of four persons) and then multiply by the square root of the desired family size.

For example, if the 2008 MBM threshold for a given region is $\$ 27,500$ for the reference family of two adults and two children:

To convert this threshold to a three-person family, the following calculation is made:
$(\$ 27,500 \div 2) \times($ square root of 3$) \Rightarrow \$ 13,750 \times 1.732 \Rightarrow \$ 23,816$
To covert the threshold to two-person family, the following calculation is made:
$(\$ 27,500 \div 2) \times($ square root of 2$) \Rightarrow \$ 13,750 \times 1.414 \Rightarrow \$ 19,445$
To convert the threshold to a single-person family, the following calculation is made:
$(\$ 27,500 \div 2) \times($ square root of 1$) \Rightarrow \$ 13,750 \times 1 \Rightarrow \$ 13,750$
2. The shelter component of the MBM thresholds is being reviewed by HRSDC.
3.

Rural: rural areas located outside a Census Metropolitan Area or Census Agglomeration. Can include some small population centres.

Less than 30,000: Census Agglomeration or population centres less than 10,000 inhabitants.
30,000-99,999: Census Agglomeration between 30,000-99,999 inhabitants.
100,000 - 499,999: Census Metropolitan Area between 100,000 - 499,999 inhabitants.
Specific city name refers to the population within the CMA or CA.

# Annex: <br> Historical low income cut-offs (LICOs) for the base years 1959 (for 1969), 1969, 1978, and 1986

Wolfson, M.C., J. M. Evans and Organization for Economic Co-operation and Development (1989). "Statistics Canada's Low Income Cut-offs, Methodological Concerns and Possibilities", Statistics Canada, A Discussion Paper.

[^0]:    1. Twenty percentage points are used based on the rationale that a family spending 20 percentage points more than the average would be in "straitened circumstances".
    2. Starting with data for 1996, the Survey of Labour and Income Dynamics (SLID) replaces the Survey of Consumer Finances (SCF).
    3. As of the Low Income Lines 2009-2010 release, a new naming convention for the geographic classification was introduced for the LICOs grouping them by five community sizes according to Rural areas outside of Census Metropolitan Areas (CMAs) and Census Agglomerations (CAs), and size of CMAs and CAs. The MBM uses these same sizes on a provincial level in addition to several CMAs and CAs. Please refer to Tables A and B of the Low Income Lines 2009-2010 release (Statistics Canada, 2011b).
    4. The LICOs were revised in early 2005 to incorporate revised weights from the 1992 Family Expenditure Survey, which were part of the 2003 Survey of Household Spending historical revision.
[^1]:    5. The model is the following: the logarithm of spending on food, shelter and clothing is a function of the logarithm of income, family size, population of the area of residence and region.
    6. It can clearly be seen that as income increases, the proportion spent on food, shelter and clothing decreases. In this case, points to the left of the intersection point between the regression curve and $63 \%$ line represent situations where more than $63 \%$ of after-tax income is spent on necessities.
    7. All dollar values are expressed in current dollars.
[^2]:    8. In 1997, the Family Expenditure Survey was replaced by the Survey of Household Spending, an annual survey. Therefore, theoretically new rebased LICOs could be produced annually (see Cotton, Webber, Saint-Pierre (1999) for more details).
[^3]:    9. 'Statistics Canada's Low Income Cut-offs: Methodological Concerns and Possibilities' (Wolfson, Evans, and OECD).
    10. A household is defined as a person or group of persons residing in a dwelling.
    11. The methodology utilized for calculating the LIMs changed substantially beginning with the release of "Low Income Lines, 2008-2009" and the 2008 Survey of Labour and Income Dynamics. These changes relate to the accounting unit utilized, the unit of analysis and the equivalence scale. For a complete description of the changes, please see "Low Income Lines, 2008-2009".
[^4]:    12. The shelter component of the MBM thresholds is being reviewed by HRSDC.
[^5]:    13. The family concept used is the economic family, that is, all persons living in the same dwelling and related by blood, marriage, common-law relationship or adoption.
    14. When using the LICO or the MBM, the economic family is the appropriate unit. When using the LIM, the household is the appropriate unit.
    15. See "What you should know" section of the 2009 Income in Canada release for a more detailed explanation (Statistics Canada, 2011a).
    16. For the calculation of this low income gap, negative incomes are treated as zero.
[^6]:    1. Can include some small population centres.
