This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the Secretariat.

This document is available on the Internet at:

www.dfo-mpo.gc.ca/csas-sccs

Région de Terre-Neuve et Labrador

**État des stocks de saumon atlantique
(*Salmo salar L.*) dans la région de Terre-
Neuve-et-Labrador (ZPS 1-14A) en 2010**

La présente série documente les fondements scientifiques des évaluations des ressources et des écosystèmes aquatiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

Ce document est disponible sur l'Internet à:

ABSTRACT

The year 2010 marks the 19th year of the commercial Atlantic salmon fishery moratorium in insular Newfoundland and the 13th year for the Labrador portion of the region. Returns of small salmon in 2010 increased relative to 2009 in 88 % of assessed rivers (14 of 16) and decreased in Campbellton River (SFA 4) and Conne River (SFA 11). Large salmon returns also increased in 2010 in 75 % of assessed rivers (12 of 16). Overall abundance of small salmon in insular Newfoundland (SFA 3-14A) reached record low levels in 2001 and 2007 and very low levels in Labrador in 2009 and 2010. Peaks in small salmon abundance, approaching pre-moratorium levels, occurred in 2004 and 2008 and 2010 in insular Newfoundland 2005-08 in Labrador. In insular Newfoundland these large variations in small salmon abundance have resulted in a long term moratorium mean (1997-2009) that is similar to the initial five year moratorium mean (1992-96) and below pre-moratorium levels (1984-91). In insular Newfoundland as was expected, overall abundance of large salmon returns increased steadily following the commercial moratorium from 1992 to 1998. However, as with small salmon, returns of large salmon experienced low levels in 2001 and 2007 but increased little in 2008. Large salmon returns increased in 2010. Within the Labrador portion of the region large salmon stock abundance has trended downwards since the late 1980's and the 2010 abundance is the lowest observed. Marine survival of smolts continues to vary widely from 11.2 % to 2.5 % in recent years. During the 2010 angling season there were no closures of the recreational fishery for environmental reasons.

RÉSUMÉ

L'année 2010 a marqué le 19^e anniversaire de l'imposition d'un moratoire sur la pêche commerciale au saumon atlantique dans l'île de Terre-Neuve et le 13^e anniversaire pour la portion du Labrador de cette région. Les remontes de petits saumons observées en 2010 ont augmenté par rapport à celles de 2009 dans 88 p. 100 des cours d'eau évalués (14 sur 16) et ont diminué dans la rivière Campbellton (ZPS 4) et la rivière Conne (ZPS 11). Les remontes de grands saumons ont également augmenté en 2010 dans 75 p. 100 des cours d'eau évalués (12 sur 16). L'abondance globale des petits saumons dans l'île de Terre-Neuve (ZPS 3-14A) a atteint des creux records en 2001 et en 2007, et des niveaux très bas au Labrador en 2009 et en 2010. Des crêtes dans l'abondance des petits saumons avoisinant les niveaux observés avant l'imposition du moratoire sont survenues en 2004, en 2008 et en 2010 dans l'île de Terre-Neuve, et de 2005 à 2008 au Labrador. Dans l'île de Terre-Neuve, ces grandes variations de l'abondance des petits saumons font en sorte que la moyenne à long terme pendant tout le moratoire (1997-2009) est semblable à la moyenne des cinq premières années d'imposition du moratoire (1992-1996) et inférieure aux niveaux antérieurs au moratoire (1984-1991). Comme on s'y attendait dans l'île de Terre-Neuve, l'abondance globale des remontes de grands saumons s'est accrue de façon constante de 1992 à 1998, après l'entrée en vigueur du moratoire sur la pêche commerciale. Cependant, comme dans le cas des petits saumons, les remontes de grands saumons ont été faibles en 2001 et en 2007, mais ont augmenté légèrement en 2008. Les remontes de grands saumons ont augmenté en 2010. Dans la portion du Labrador de cette région, l'abondance des stocks de grands saumons affiche une tendance à la baisse depuis la fin des années 1980, mais l'abondance de 2010 a atteint le niveau le plus bas observé. La survie des saumoneaux en mer a continué de varier considérablement de 11,2 à 2,5 p. 100 au cours des dernières années. Au cours de la saison de pêche à la ligne 2010, il n'y a pas eu de fermeture des pêches sportives pour des raisons environnementales.

INTRODUCTION

A five year Atlantic Salmon Management Plan was introduced in 1984 to rebuild depressed stocks in mainland Canada and southwestern Newfoundland. The main focus of the 1984 plan was to reduce fishing mortality of large salmon (mainly virgin multi-sea-winter salmon) through season changes in the commercial fishery, catch restrictions in the recreational fishery (e.g., grilse-only retention) and a commercial licence retirement program (O'Connell et al. 1992a; May 1993). In an effort to further reduce commercial catches, a quota management system was used in 1990 and 1991 (O'Connell et al. 1992b; May 1993). In general, restrictions in the commercial fishery did not result in increased numbers of Atlantic salmon spawners (grilse and large salmon) in Newfoundland or Labrador (O'Connell et al. 1992a) and only 58 % of the 1991 commercial quota was caught (O'Connell et al. 1992b).

In 1992, several major changes were introduced to the management of Atlantic salmon (*Salmo salar* L.) in Newfoundland and Labrador. A five-year moratorium was placed on commercial salmon fishing in the island portion of the province. A quota on the number of small salmon (<63 cm fork length, FL) that could be retained in the recreational fishery was introduced in each Salmon Fishing Area (SFA) in 1992 and 1993. Once the quota had been reached only catch-and-release fishing was permitted. Quotas were eliminated in 1994 and the seasonal bag limit for the retention of small salmon was lowered from eight to six fish. In Labrador two of the six fish retained could be large and in 1996 retention of large salmon was reduced to one in Labrador.

As well in 1992 quotas for the Labrador commercial fishery, first introduced in 1990, were further reduced and a voluntary retirement of commercial salmon licenses was instituted for the entire province. Beginning in 1997, the commercial fishery was closed in the Straits area of Labrador in Salmon Fishing Area (SFA) 14B and then in 1998, it was closed in the remaining SFAs 1 and 2 (Fig. 1). Fishers were offered a buyout which most accepted.

In 1997 further restrictions were implemented to manage the recreational Atlantic salmon fishery. Returns of small salmon too many rivers in insular Newfoundland were substantially lower than expected (Dempson et al. 1998; O'Connell et al. 1998a). As a result of this and uncertainties regarding levels of future returns, the 1998 management plan was much more conservative than for previous years. The seasonal bag limit for small salmon in insular Newfoundland was initially reduced to one and increased to an additional three following an in-season review. The use of barbless hooks for all angling on scheduled salmon waters was initiated in July 1998 for insular Newfoundland and in 1999 for Labrador. The retention of large salmon (≥ 63 cm FL) has remained prohibited in all of insular Newfoundland since 1985. Large salmon in insular Newfoundland are comprised mainly of repeat spawning grilse, with the exception of some rivers in SFA 13 (O'Connell et al. 2006a).

In 1999, a three year Atlantic salmon management plan introduced an Adaptive Management Strategy and a River Classification System. The classification system was used to develop retention levels based on the health of individual salmon stocks, without jeopardizing conservation goals. This was a major departure from managing salmon on a more regional or SFA basis. Details of the three year plan and a description of the River Classification System are provided in DFO (1999). Five year management plans were introduced in 2002 (DFO 2002) and 2007 (DFO 2007), wherein the River Classification System, though variously modified, was retained. Management measures also included environmental protocols for closures and special management plans developed in consultation with local watershed and stewardship groups (DFO 2007).

The failure of stocks to rebuild to expected levels resulted in a commercial fishery moratorium in 2000 for all eastern Canada.

In 2001, as part of a 2001-05 Management Plan, several additional rivers in southern Labrador crossed by the new Trans Labrador Highway were added to the list of scheduled rivers and restricted to individual bag limits of two small salmon retained.

In 2010 the retention of large salmon was prohibited in Labrador.

In response to the Supreme Court of Canada decision interpreting Section 35 of the Constitution Act of 1982, the Department of Fisheries and Oceans (DFO) provided resource access to Aboriginal groups for food, social and ceremonial purposes (FSC). In 1999-2004, a FSC or subsistence fishery of 10 t was available for members of the Labrador Inuit Association in the north as well as the Lake Melville area, both located in SFA 1. The Innu Nation also fish for salmon in Lake Melville and from the community of Natuashish. They generally restrict themselves to harvests of around 3 t. Beginning in 2000 residents of Labrador were able to fish in the sea for brook trout (*Salvelinus fontinalis* Mitchell) and Arctic charr (*Salvelinus alpinus* L.) with a permitted bycatch of four salmon. This bycatch was reduced to 3 salmon in 2011. In 2004, members of the Labrador Métis Nation (now the Nunatukavut Community Council) on the south coast of Labrador negotiated a subsistence fishery of 10 t with the Department of Fisheries and Oceans in the area between Fish Cove Point and Cape St. Charles (SFA 2).

The West Greenland commercial salmon fishery, which was closed for the 1993 and 1994 fishing seasons, was re-opened in 1995 and closed again in 1999, leaving only a small subsistence fishery in 2000. In 2001, the commercial Greenland fishery was opened with a structured quota system that depended on abundance based on in-season catches and historical averages to determine potential landings. Although there have been no recent tagging studies to document the distribution of Labrador salmon at sea, some Labrador origin multi-sea winter salmon may be caught in the Greenland fishery similar to what was shown for Labrador stocks in earlier studies by Pratt et al. (1974). In 2002-03, the Greenland fishery was restricted to a local fishery of 22 t and in 2004 it was reduced to a subsistence consumption fishery only, estimated to be around 20 t. Since then, landings have remained low averaging about 25 t per year.

The status of Atlantic salmon stocks in the Newfoundland and Labrador Region (SFAs 1-14A) (Fig. 1) are assessed annually based on trends in abundance of various life stages relative to historical values and percent conservation requirement achieved. For the purpose of these assessments, Atlantic salmon stocks have been defined at the individual river level. A summary of the life history and ecology of Atlantic salmon in eastern Canada can be found in O'Connell et al. (2006a).

METHODS

In 2010, the status of Atlantic salmon stocks of insular Newfoundland (SFAs 3-14A) were assessed using recreational fishery data derived from the License Stub Return System (O'Connell et al. 1996a, 1998b) and data collected at monitoring facilities. Given that recreational fishery data have not been finalized for 2010, data are preliminary where appropriate. In Labrador Conservation and Protection (C&P) staff and camp operator data are used for SFA 1. For SFA 2, a blend of License Stub Return System (LSRS) and camp operator data are used; whereby camp operator data are used for Eagle and Sand Hill rivers and LSRS data for all other rivers. The retained catches reported by these two methods were similar. For SFA 14B rivers, the catch statistics are derived from the License Stub Return System.

Numbers of small (<63 cm FL) and large (≥ 63 cm FL) Atlantic salmon were reported as direct counts from monitoring facilities as well as total returns that included angling removals below the count location. Smolts were assessed at six rivers using counting fences or mark-recapture methods (Dempson and Stansbury 1991; Schwarz and Dempson 1994).

Conservation requirements for Atlantic salmon rivers in insular Newfoundland were calculated based on accessible habitat area and threshold egg deposition rates (O'Connell and Dempson 1995; O'Connell et al. 1996b). Egg deposition rates for conservation were set at 2.4 eggs per m^2 of river rearing habitat and 368 eggs per hectare of lake habitat in SFAs 3-13. Lake habitat for SFA 14A was set at a lower rate of 105 eggs per hectare (O'Connell and Dempson 1995; O'Connell et al. 1997). Conservation requirements for Labrador rivers in SFAs 1-2 are based on 1.9 eggs per m^2 of river rearing habitat and in SFA 14B they are based on 2.4 eggs per m^2 of river rearing habitat and 368 eggs per hectare of lacustrine habitat.

Conservation requirements are considered to be a threshold reference point corresponding to a level at which populations should not be allowed to fall below. The consequence of egg depositions below conservation to the long-term sustainability of the stock are unknown but the likelihood of deleterious effects are greater when egg depositions are below conservation.

In most cases, 2010 data were compared to the appropriate pre-moratorium means, initial five year moratorium means, and previous five or six year means as appropriate. Major management changes to the commercial fishery should be kept in mind when evaluating pre-moratorium means (O'Connell et al. 1992a; 1992b). The initial five year moratorium mean corresponds to the period when fish otherwise caught in the commercial fishery were expected to return to rivers thereby increasing the total number of spawners.

In addition to examining salmon stock abundance in individual rivers, stocks from all monitored rivers were combined to derive composite indices of abundance for Newfoundland. This indices provide an overall perspective of trends in Atlantic salmon abundance for the region. Trends in abundance were analysed by fitting general linear models (GLM) separately to log_e transformed total returns of small and large salmon. Data were transformed to provide a standardized metric of relative changes in individual stock sizes. Therefore the unit for the abundance index is not an absolute abundance but is related to a geometric mean of individual river abundances. Details of the methodology used for the composite index are summarized in Dempson et al. (2004). Index values for the pre-moratorium period 1984-91 were adjusted to account for marine exploitation. In all cases, marine exploitation rates used

were the average of the median values obtained from nine rivers as described in Dempson et al. (2001) and were 45.3 % for small salmon and 74.2 % for large salmon.

RESULTS AND DISCUSSION

The most recent CSAS research document published for the status of Atlantic salmon stocks of insular Newfoundland was based on data to 2005 (O'Connell et al. 2006b). Therefore, much of the discussion in the current assessment summarized trends from 2006–09.

RECREATIONAL FISHERY DATA

Recreational fishery data were reported for the period 1994-2010. Fishing effort was presented as rod days, defined as any day or part of a day on which each angler fishes. Catch and effort data in 2010 were compared to the long term mean (1994-2010) as well as the previous 5/6 year means. The number of angler days lost due to river closures varies from year to year. This variability must be kept in mind when comparing yearly catch and effort information and is why rivers without monitoring facility counts are not routinely assessed. In 2010 there were no closures due to environmental conditions.

Catches of small and large salmon for the region (SFAs 1-14A) are presented in Appendix 1a-b for Labrador and insular Newfoundland respectively. Catch data was also divided into five subdivisions and presented in Appendix 1b-f for (i) Labrador (ii) Northern Peninsula East and Eastern (SFAs 3-8), (iii) South (SFAs 9-11), (iv) Southwest (SFAs 12-13), and (v) Northern Peninsula West (SFA 14A). Data for each individual SFA are shown in Appendix 1g-u. Catch per unit effort (CPUE) was calculated using all retained and released fish.

Labrador (SFAs 1-14B)

Since 2005, the catch of small salmon (retained and released) declined to 2007, peaked above the five year mean in 2008, declined again in 2009 and increased slightly in 2010 but remained below the previous five year mean (Fig. 3). The overall trend is one of decline for the last ten years since the peak in 2000. Effort (rod days) has declined since the peak in 2000 with the 2010 value being the lowest in the time series. CPUE trended upwards from 2000 to 2006 and has trended downwards since (Fig. 3).

Insular Newfoundland (SFAs 3-14A)

Since 2005, the catch of small salmon (retained and released) and large salmon (released) declined to 2007, peaked above the long term mean in 2008 and declined again in 2009, increased in 2010 but remained above the previous five year mean (Fig. 4). Effort (rod days) and CPUE followed similar trends (Fig. 4).

Subdivisions of Insular Newfoundland

The overall trend in the catch of small and large salmon observed in insular Newfoundland (Fig. 4) was similar for SFAs 3-8 and 9-11 and similar for SFAs 12-13 and 14A (Figs. 5-8).

Northern Peninsula East and Eastern (SFAs 3-8): The 2010 catch of small salmon declined from highs observed in 2008 but remained above the five year mean. Large salmon catch increased over the 2009 low and was similar to the previous five mean. Trends in Effort and

CPUE for SFAs 3-8 (Fig. 5) were similar to those observed for insular Newfoundland (Fig. 4) and were at or above the previous five year mean.

South SFAs 9-11: The 2010 catch of small salmon in SFAs 9-11 declined from the previous two years but was at the five year mean. Large salmon catch increased over the 2009 low and was similar to the previous five mean (Fig. 7). Effort declined in 2010 while CPUE for SFAs 9-11 increased above the previous five year mean.

Southwest (SFAs 12-13): Catch of small and large salmon in 2010 continues to fluctuate, and increased over 2009 being similar to the five year mean. Trends in Effort for SFAs 12-13 (Fig. 7) continued to decline from 2009 and remained below the five year mean. CPUE for SFAs 12-13 increased dramatically from 2009 and was above the five year average (Fig. 7).

Northern Peninsula West (SFA 14A): The catch in SFA 14A of small and large salmon increased substantially above the long term mean since 2005 (Fig. 8). Trends in Effort for SFA 14A (Fig. 8) increased over 2009 and were above the five year mean. CPUE for SFA 14A increased dramatically in 2010 and remains well above the long term average (Fig. 8).

Recreational Salmon Fishery Licences

The average number of recreational salmon fishery licences sold in Newfoundland and Labrador was 24,493 for the five year period preceding the commercial moratorium (1987-91) and 19,350 for the moratorium years (1992-2010) (Fig. 9). Since 2007, the number of licences sold has increased such that 2010 was the highest since 1997.

SUBSISTENCE FISHERY DATA

Atlantic salmon harvest

Table 8 details the harvest of Atlantic salmon in the 2010 subsistence fisheries for SFA's 1 and 2. The 2010 harvest was the second highest in the time series.

MONITORING FACILITY DATA

Smolt Production

In 2010, smolts were assessed on six rivers: Sandhill River (SFA 2), Campbellton River (SFA 4), Northeast Brook (Trepassey) (SFA 9), Rocky River (SFA 9), Conne River (SFA 11), and Western Arm Brook (SFA 14A). Counting fences were used at all sites except Conne River where a mark-recapture method was used (Dempson and Stansbury 1991; Schwarz and Dempson 1994). Smolt production increased for four watersheds namely Sandhill River, Campbellton River, Rocky River and Western Arm Brook (Table 1).

Smolt to Adult Survival (Small Salmon)

Smolt to adult survival for Sandhill River in Labrador is based on smolt to small salmon in year X and smolt to large salmon in year X + 1. For the 2009 year class of smolt the sea survival was 3.7 % up from 2008 but down substantially from 2007.

Smolt to adult survival (small salmon) for insular Newfoundland varied widely from 2006 to 2010 (Table 1, Fig. 10). Mean marine survival rates decreased from 7.2 % in 2006 to 3.3 % in 2007, increased to 7.6 % in 2008 and declined again to 4.8 % in 2009. Survival rates experienced during this time period included a record high of 15 % in Western Arm Brook (SFA 14A) in 2006 and a record low of 1.3 % in Rocky River (SFA 9) in 2007 (Table 1, Fig. 10) and a record high in Rocky River in 2010 of 6.8 %. In 2010 smolt to adult survival increased in 4 out of 5 monitored rivers; Conne River experienced one of the lowest values in the time series. Given that the number of small salmon would include a small portion of repeat spawners, marine smolt survival would be slightly underestimated.

Smolt to adult survival rates adjusted for commercial harvest (Dempson et al. 1998) were also included in Fig. 8 for Sandhill River, Conne River, Northeast Brook (Trepassey), and Western Arm Brook. Pre-moratorium marine survival rates approached 15 % for Conne River and Northeast Brook (Trepassey). Marine survival for both of these stocks fell throughout the late 1980s and early 1990s while Rocky River has experienced low survival for most years in the series.

MONITORING FACILITY ADULT COUNTS, TOTAL RETURNS, AND CONSERVATION REQUIREMENT

Total returns of small salmon (Table 2) and large salmon (Table 4) at monitoring facilities in 2010 are compared to the pre-moratorium mean, respective five/six year moratorium mean, and moratorium mean (Tables 4-5). Comparisons are made for proportion of total returns of large salmon (Table 6).

Percent conservation requirement achieved was compared to the respective pre-moratorium mean, 5/6 year moratorium mean, and moratorium mean.

Labrador (SFAs 1-14B)

Abundance Index: Figure 11 illustrates the indices of small and large salmon abundance for all of Labrador. When adjusted for marine exploitation, the highest abundances of small salmon occurred during pre-moratorium years (prior to 1998). Since then, overall abundance has increased in 2000, declined through 2004, increased 2005-08 to some of the highest levels observed in the series. The index value for 2008-09 is well below the previous six year mean. Large variations continue in small salmon abundance. There is a continuous declining trend in the abundance index for large salmon which commenced in the early 1980's. The 2010 abundance of large salmon is the lowest in the time series and is below the previous six year mean.

SFA 1

Total Returns: Information on total returns of small and large salmon (Tables 2-3, Fig. 13) in 2010 was available for English River. Returns of small salmon rose sharply following 2003 up to and including 2007 and since then have been in decline. The 2010 returns were below the six (previous generation) year mean however returns for 2010 are above the moratorium mean (Table 2). Large salmon returns in 2010 were down significantly from an upwards trend commencing in 2004. The 2010 returns of large salmon were similar to the previous six year and moratorium means.

The proportion of large salmon in total returns in 2010 was above the previous six year and moratorium means. English River does not have a large component of 2SW salmon in its stock composition, it is a grilse river.

Conservation Requirement: In 2010 English River achieved 86 % of its conservation requirement. The proportion of the conservation requirement achieved was above the moratorium average but below the previous generation average.

SFA 2

Total Returns: Information on total returns of small and large salmon (Tables 2-3, Fig. 13) in 2010 was available for Sandhill River and Southwest Brook. Returns of small salmon rose sharply following 2003 up to and including 2005 and increased in 2010 over 2009. The 2010 returns were below the previous 6 year mean. Large salmon returns in 2010 declined and were below the previous 6 year mean.

The proportion of large salmon in total returns declined in 2010 over 2009. For Southwest Brook the proportion of large salmon in the returns was below the mean whilst for Sandhill River the proportion was above the mean.

Conservation Requirement: In 2010 Southwest Brook and Sandhill River achieved 57 % and 54 % of their respective conservation requirements.

SFA 14B

There are no assessment facilities in this SFA.

Insular Newfoundland (SFAs 3-14A)

Abundance Index: Figure 12 illustrates the indices of small and large salmon abundance for all of insular Newfoundland. When adjusted for marine exploitation, the highest abundances of small salmon occurred during pre-moratorium years (1984-91). Since then, overall abundance has declined. The index value for 2005, small reversed a trend of steady increase that approached pre-moratorium levels in 2004. For small salmon, the abundance index continued to decline to a record low in 2007, peaked dramatically and returned to 2004 levels in 2008, and declined in 2009. Large variations in small salmon abundance from 1997 to 2008 resulted in a similar mean to that of 1992-96 and below pre-moratorium levels. In 2010 small salmon abundance peaked since the moratorium and approached the pre moratorium mean. As with small salmon, large salmon abundance declined from 2004 to 2007, but increased only slightly in 2008. Large salmon declined in 2009, reaching the lowest level since 1993. Large salmon abundance in 2009 was similar to the 1992-96 mean and below both the pre-moratorium and 1997-2008 means. The 2010 abundance of large salmon was above the previous five year mean.

Subdivisions of Insular Newfoundland:

SFA 4

Total returns: Information on total returns of small (Table 2, Fig. 15) and large (Table 3, Fig. 15) salmon in 2009 was available for Exploits River (Bishop's Falls), Gander River and Campbellton River. Total returns to Gander River have been estimated from counts at Salmon

Brook tributary since 2000. The confidence limits for the Gander estimates were included in (O'Connell et al 2001; O'Connell 2003). Returns of small salmon to these SFA 4 rivers experienced declines in the few years prior to 2007 (Exploits 2003-07, Campbellton 2005-07, Gander River 2004-07) and then increased above the previous 5 year mean in 2008 and 2009 (Table 2, Fig. 15). Small salmon returns to Exploits River and Campbellton River approached or exceeded record highs in 2008 and 2009 and remained greater than the pre-moratorium and 1992-1996 means (Tables 2 and 15). However, returns of small salmon to Gander River in 2009 were less than the 1992-1996 mean (Table 2). In 2010 returns of small salmon was above the five year and moratorium means.

Returns of large salmon to the Exploits River and Campbellton River have generally increased since the early 2000s and are above the pre-moratorium (1984-91 series available for Exploits only) and 1992-96 mean (Table 3, Fig. 15). However, returns of large salmon to the Gander River have declined since 2004 and are well below the 1992-96 mean (Table 3, Fig. 15). In 2010 returns of large salmon increased on all monitored rivers with Exploits and Campbellton being above the previous five and moratorium means whilst Gander was below the previous five year and moratorium means.

The proportion of large salmon in total returns (Table 6, Fig. 15) reflects changes in both the small and large salmon counts. For the Exploits River, the proportion of large salmon increased from 2005 to 2010. For Campbellton River the portion of large has trended upwards since 2005. In 2010, the proportion of large salmon in total return increased for the three monitored rivers. The proportion of large salmon in Gander River has steadily declined since 2006.

Conservation Requirement (Table 7): The percent conservation requirement on Exploits River declined from 49 % in 2005 to 44 % in 2007, and increased in both 2008 (60 %), 2009 (65 %) and 2010 (81 %). The Exploits River was also assessed in three sections. The Lower section has exceeded conservation requirement since 2006 and was 204 % in 2010, the second highest on record, 172 % in 2009. The Middle section declined to 27 % in 2007 and increased in 2008 (60 %) and 2009 (53 %). In 2010 the highest rate was achieved. The Upper section only achieved 1-5 % conservation requirement during the period 2006-10. Values for the Upper Exploits River pre-moratorium mean (1984-91) were the result of artificial stocking. Since 1991, spawning adults were moved through the Red Indian Lake fishway. The Exploits River was the site of major Atlantic salmon enhancement program that were conducted between the late 1950s and early 1990s (O'Connell et al. 1983; O'Connell and Bourgeois 1987; Bourgeois et al. 2001). Egg deposition on Campbellton River has exceeded conservation requirement in all years and reached record levels of 360 % in 2008 and 371 % in 2009 and 381 % in 2010. Conservation requirement on Gander River were not met in 2006 (87 %) or 2007 (72 %), but attained in 2008 (112 %) and 2009 (101 %). The 2010 conservation requirement was the highest in the time series of 131 %.

SFA 5

Total returns: Information on total returns of small (Table 2, Fig. 17) and large (Table 3, Fig. 17) salmon in 2010 was available for Middle Brook, Terra Nova River (Lower), and Northwest River (Port Blandford, Terra Nova National Park). Returns of small salmon to these SFA 5 rivers generally declined from 2004 to 2007, increased above the previous 5 year mean in 2008, declined in 2009 and increased in 2010 (Table 2, Fig. 17). In Middle Brook, small salmon returns in 2009 and 2010 remained above the previous 5 year mean, whereas, Terra Nova River and Northwest River fell below the previous 5 year mean in 2010 (Fig. 17).

Returns of small salmon to Northwest River in 2010 were amongst the highest observed but the 2009 were the lowest recorded since 2001. Small salmon returns to Middle Brook and Terra Nova in 2009 and 2010 were greater than the pre-moratorium mean (1984-1991) and the 1992-09 mean (Table 2) for all three monitored rivers. Large salmon returns to the three SFA 5 rivers increased in 2008 over 2007 but declined in 2009 below the 1992-1996 and previous 5 year mean (Fig. 17) and increased in 2010 to at the level or above the previous means.

The proportion of large salmon in total returns to Middle Brook declined from 2007 to 2010 (Table 6); for Terra Nova River it declined from 2007-09 but increased in 2010, but increased in Northwest Brook from 2007 to 2009 and declined in 2010. The proportions of large salmon for the three SFA 5 rivers are below the 1992-09 mean (Table 6) and the previous five year mean.

Conservation Requirement (Table 7): Middle Brook achieved conservation requirement in all years of the time series. The percent achieved declined from 2008 (232 %) to 2009 (170 %) and increased to 273 % in 2010. Terra Nova River has never attained egg requirement and the percent achieved declined from 2008 (61 %) to 2009 (40 %) and increased to 70 % in 2010. It should be noted that accessible habitat for anadromous Atlantic salmon in Terra Nova River more than doubled with the establishment of fish passage at Mollyguajeck Falls in 1985 (O'Connell et al. 2000). Initial enhancement activity on Terra Nova River started in 1952 with the construction of a fishway around impassable falls in the upper segment (O'Connell et al. 2000; Mullins et al. 2003). Northwest River has never attained egg requirement and the percent achieved declined from 2008 (92 %, second highest on record) to 2009 (37 %) and increased to 67 % in 2010. Enhancement activities have also taken place on Northwest River. In 1948, the area above Northwest Falls (3.2 km from the river mouth) was made accessible to anadromous salmon with the blasting of a fish passage (Cote et al. 2001).

SFA 9

Total returns: Information on total returns of small (Table 2, Fig. 19) and large (Table 3, Fig. 19) salmon to SFA 9 in 2010 was available for Northeast Brook (Trepassey) and Rocky River. As with the East Coast SFA 5 rivers, total returns of small salmon to Northeast Brook and Rocky River declined well below the previous 5 year mean in 2007, increased in 2008, declined in 2009 and increased again in 2010 (Table 2, Fig. 19). Small salmon returns to Northeast Brook in 2010 were below the pre-moratorium and above 1992-2009 means. A record high return of small salmon to Rocky River was recorded in 2010 and returns remained above all means. Returns of large salmon followed a similar pattern from 2007 to 2009, however, the previous 5 year mean has declined since 2005 and numbers are currently below the 1992-2009 mean (Table 3). The lowest return of large salmon to Northeast Brook was recorded in 2009 and the numbers have declined steadily since pre-moratorium years (Fig. 14).

The proportion of large salmon in total returns to Northeast Brook and Rocky River declined from 2007 to 2009 and are below the 1992-09 mean and the previous five year mean (Fig. 20v).

Conservation Requirement (Table 7): Northeast Brook (Trepassey) has achieved conservation requirement in all years. The percent achieved declined from 2008 (232 %) to 2009 (114 %) and increased in 2010 (188 %). Atlantic salmon enhancement initiatives occurred on Rocky River during the period 1984-96. A fishway was constructed to allow access beyond the

impassable waterfall at the river mouth (Bourgeois 1998; Mullins et al. 2003). The percent conservation requirement achieved for Rocky River reached a record high of 98 % in 2010.

SFA 11

Total returns: Information on total returns of small (Table 2 and Fig. 19) and large (Table 3 and Fig. 19) salmon is available for Conne River and Little River. As with the SFA 9 rivers, total returns of small and large salmon to Conne River declined below the previous 5 year mean in 2007, increased in 2008, declined again in 2009 and remained similar to 2009 in 2010 (Table 2 and 3, Fig. 19). Numbers of small and large salmon in Conne River remain below the pre-moratorium and 1992-09 means. Returns of small salmon to Little River declined in 2007 and increased in 2008-10. Large salmon have declined in Little River since 2006 and the lowest count was recorded in 2009 (Fig. 14).

The proportion of large salmon in total returns to Conne River and Little River increased in 2010 and are below the pre-moratorium, 1992-09 and five year means (Fig. 20).

Conservation Requirement (Table 17): Percent conservation requirement achieved for Little River increased from 31 % in 2008 to 98 % in 2009 to 118 % in 2009. This system was stocked with swim-up fry in the 1980s and 1990s (Bourgeois et al. 1997) and currently undergoes spawner transfer activities. Percent conservation requirement achieved for Conne River declined from 117 % in 2008 to 72 % in 2009 to 69 % in 2010.

SFA 13

Total returns: Information on total returns of small (Table 2 and Fig. 21) and large (Table 3 and Fig. 21) salmon is available for Harry's River (Gallants Fence). Returns to Harry's River were estimated using a counting fence on the mouth of Pinchgit Brook (a tributary located 48 km upstream) and various spawner surveys from 1992-2002 (Mullins et al. 1996, 1997, 2001; Mullins and Caines 2000). A fence located near the mouth of Harry's River was used from 2003 to 2005. Since 2006, counts on Harry's River have been conducted 25 km upstream near the community of Gallants. A spawner survey (snorkel method) was conducted in the lower reaches of the river below Gallants in 2006, 2007 and 2008. The spawner survey was not conducted in 2009 due poor environmental conditions. The number of spawners below Gallants in 2010 was estimated from snorkel surveys conducted below Gallants counting fence. As with many insular Newfoundland rivers, returns of small salmon to Harry's River declined well below the previous 5 year mean in 2007, peaked in 2008, declined in 2009 and rose again in 2010 (Table 2, Fig. 21). Returns of small and large salmon are currently above the 1992-09 but below the previous five year means respectively (Tables 2 and 3, Fig. 21).

The proportion of large salmon in total returns to Harry's River increased in 2009 and decreased in 2010 and is at the 1992-2009 mean but below the five year mean (Fig. 22).

Conservation Requirement (Table 10): Harry's River met conservation requirement for the first time on record in 2006 (116 %) and again in 2008 (108 %), but declined below conservation in 2009 (90 %) and increased in 2010 (94 %).

Total returns: Information on total returns of small (Table 2 and Fig. 21) and large (Table 3 and Fig. 21) salmon is available for Torrent River and Western Arm Brook. As with many insular Newfoundland rivers, returns of small salmon to these two SFA 14A rivers declined

well below the previous 5 year mean in 2007, peaked in 2008, declined in 2009 and increased in 2010 (Table 2, Fig. 21). Returns of small salmon to Torrent River are currently above the 1992-09 mean and the pre-moratorium mean (Table 2, Fig. 21). The five year mean for small salmon returns has generally increased on Western Arm Brook since 1997 and total returns were above the pre-moratorium and 1992-09 means in 2010 (Table 2, Fig. 21). Returns of large salmon to Torrent River were the highest on record in 2006, declined dramatically in 2007, and approached record high levels in 2008, 2009 and 2010 (Table 3, Fig. 21). Returns of large salmon to Western Arm Brook declined from 2006 to 2008, increased slightly in 2009 and in 2010 rose above the 1992-09 mean. Large salmon in Western Arm Brook are currently above the 1992-96 mean but below the five year mean (Table 3, Fig. 21).

The proportion of large salmon in total returns to Torrent River increased from 2007 to 2009, declined in 2010 and is above the pre-moratorium and 1992-96 means (Fig. 22). Conversely, the proportion of large salmon in Western Arm Brook remains below the 1992-09 mean, decreasing from 2007 to 2008, increasing slightly in 2009 and increasing slightly in 2010 as well (Fig. 22).

Conservation Requirement (Table 10): Torrent River and Western Arm Brook have achieved conservation requirement in all years. Percent achieved declined on both rivers from 2008 to 2009 (Torrent River: 1203 % to 750 %, Western Arm Brook: 611 % to 341 %) and increased to 1063 % and 598 % respectively. Enhancement program were carried out on Torrent River from 1965 to 1976, which included the construction of a fishway around an impassable waterfall located 2 km from the river mouth (Mullins et al. 2003).

SUMMARY AND CONCLUSIONS

Smolt to adult survival in 2010 ranged from 10.3 % for Campbellton River to 2.5 % for Conne River. Smolt production in 2010 decreased from 2009 in two of the five assessed rivers (Northeast Brook and Conne River).

Returns of small salmon in 2010 increased relative to 2009 in 88 % of assessed rivers (14 of 16) and decreased on Campbellton River (SFA 4) and Conne River (SFA 11).

Returns of large salmon in 2010 increased from 2009 in 75 % of assessed rivers (12 of 16). Overall abundance of small salmon in insular Newfoundland (SFA 3-14A) declined dramatically from 2004 to 2007 (reaching record low levels), peaked dramatically and returned to 2004 levels in 2008, and declined in 2009 and increased again in 2010.

Conservation requirements in 2010 were only met in 50 % of assessed rivers (8 of 16). The percent conservation requirement achieved in 2010 increased from 2009 in 13 rivers (81 %).

¹Includes Native food fishery.

* 57733 excludes 5016 removed to Roti Bay.

4154 small salmon for Conne River 1996 excludes 286 fish from the wild smolt aquaculture experiment.

Table 2. Total returns of small salmon to rivers in Newfoundland and Labrador by Salmon Fishing Area (SFA), 1984-2010. Table includes means and 95% confidence intervals for pre-moratorium, moratorium and previous generation.

* Preliminary

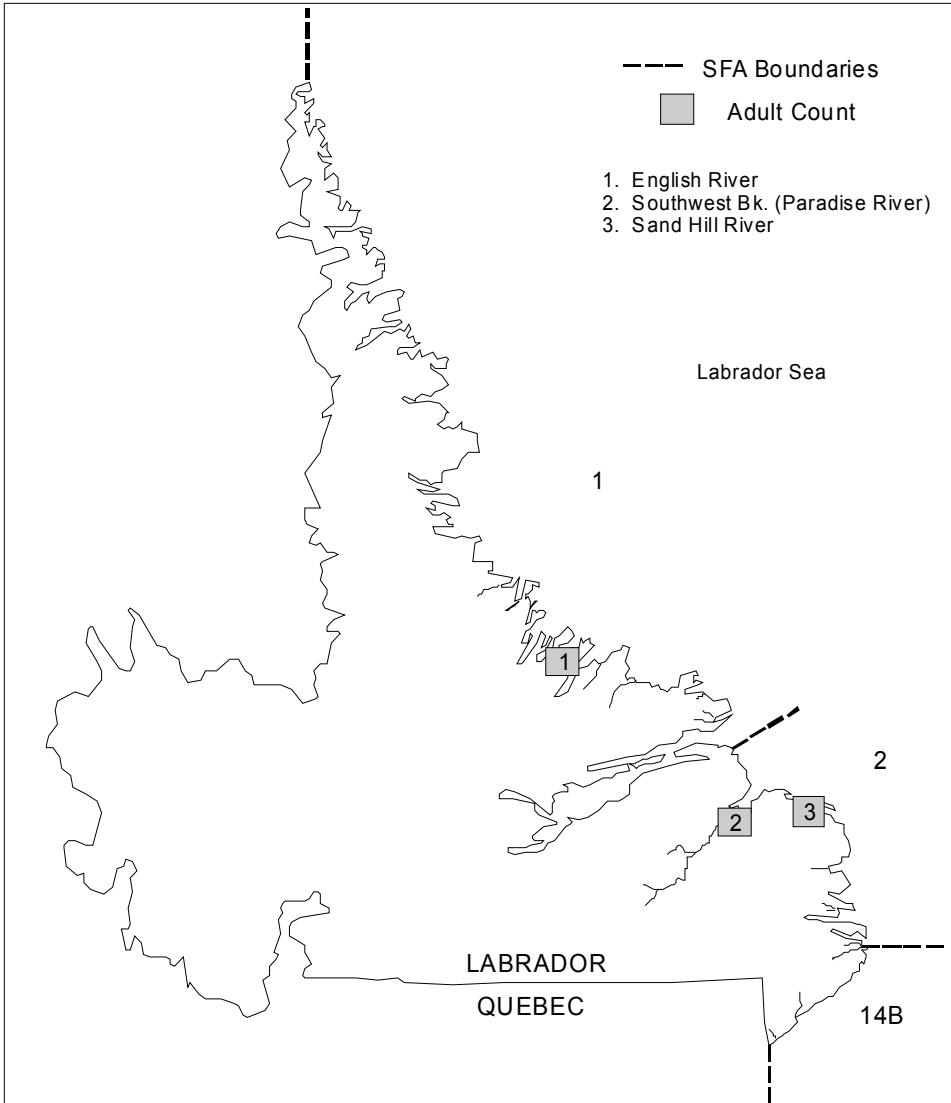

Figure 1. Map showing Salmon Fishing Areas 1, 2 and 14B (SFAs) and locations of counting facilities in Labrador, 2010.

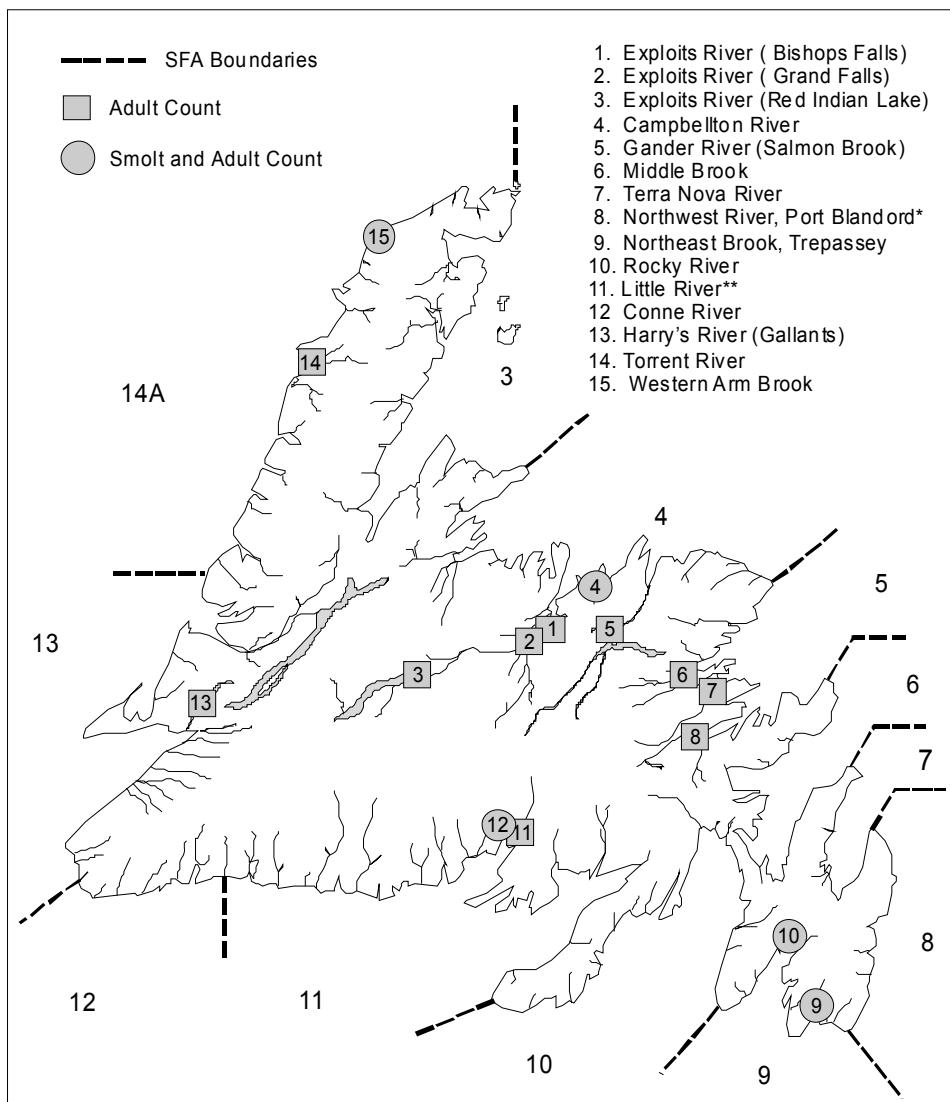

Figure 2. Map showing Salmon Fishing Areas 3-14A (SFAs) and locations of counting facilities in insular Newfoundland, 2010. *Northwest River (Port Blandford) fence is managed by Terra Nova National Park.
**Little River fence is managed by Miawpukek First Nation, Conne River.

Labrador (SFAs 1, 2 & 14B)

Recreational Fishery

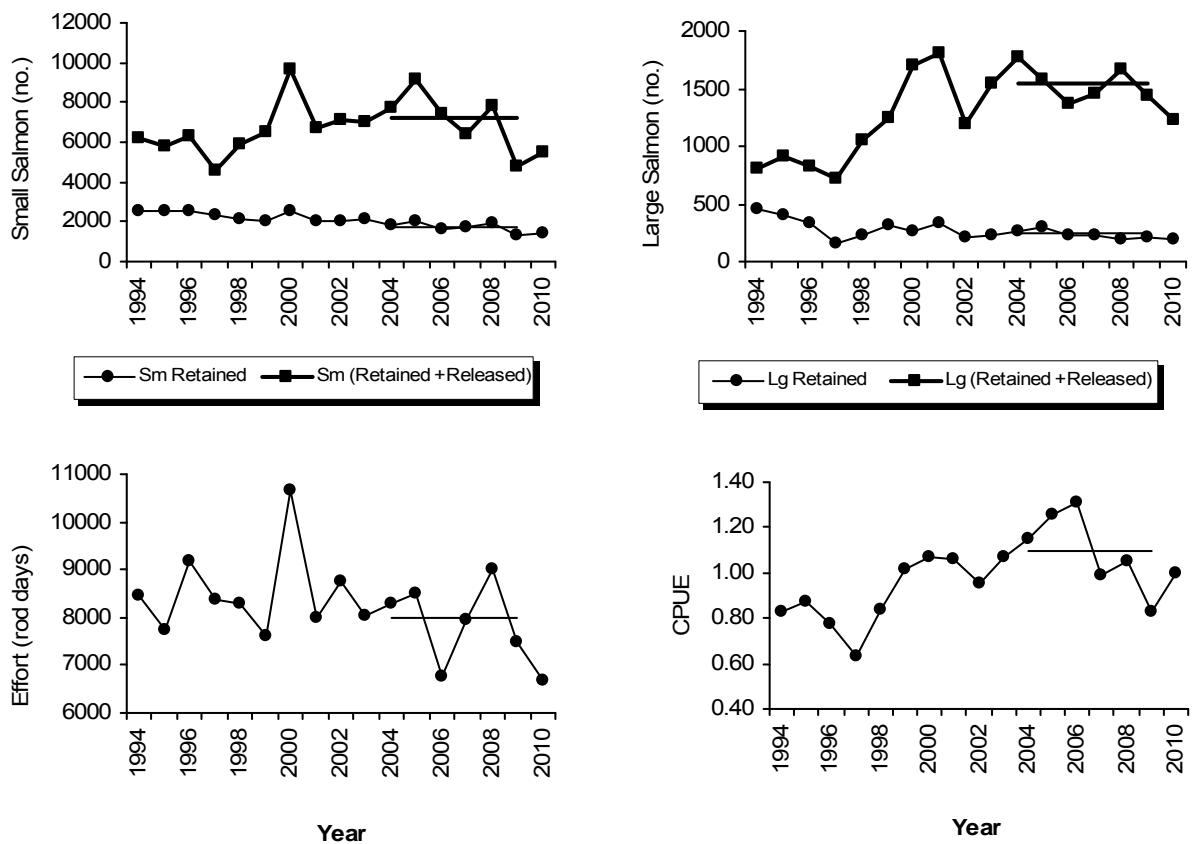

Figure 3. Recreational catch of small and large salmon, effort, and catch per unit of effort (CPUE), 1994-2010 for Labrador (SFAs 1, 2 & 14B). Horizontal lines represent the previous generation mean, 2004-2009.

Insular Newfoundland (SFAs 3 – 14A)

Recreational Fishery

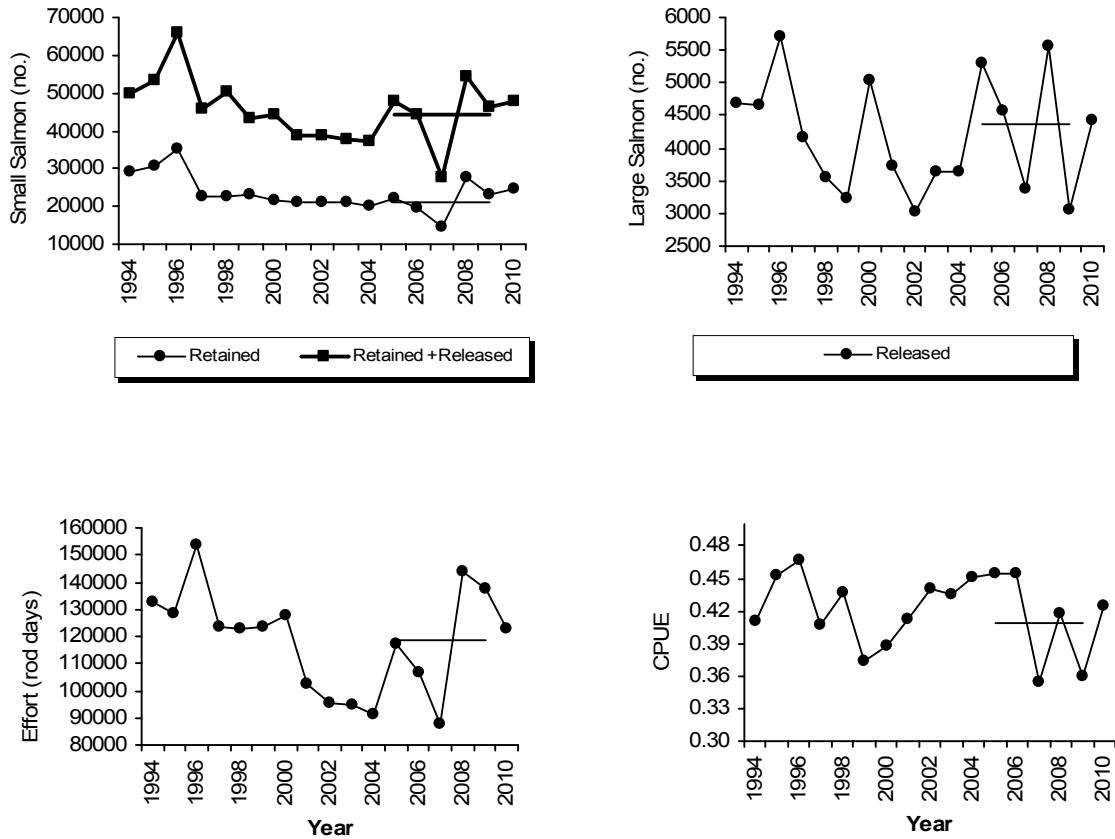

Figure 4. Recreational catch of small and large salmon, effort, and catch per unit of effort (CPUE), 1994–2010 for insular Newfoundland (SFAs 3 – 14A). Horizontal lines represent the previous generation mean, 2005–2009.

Northern Peninsula East & Eastern (SFAs 3 – 8)

Recreational Fishery

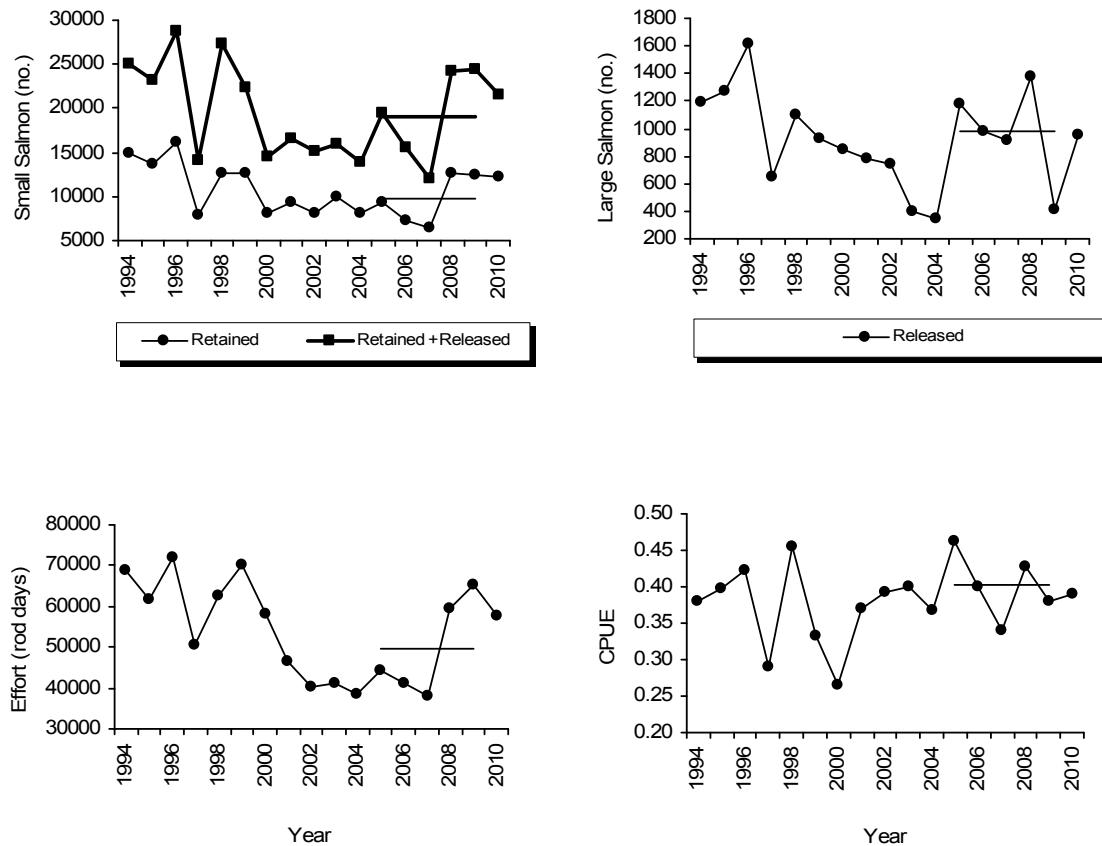

Figure 5. Recreational catch of small and large salmon, effort, and catch per unit of effort (CPUE), 1994–2010 for Northern Peninsula East & Eastern (SFAs 3 – 8). Horizontal lines represent the previous generation mean, 2005–2009.

South (SFAs 9 – 11)

Recreational Fishery

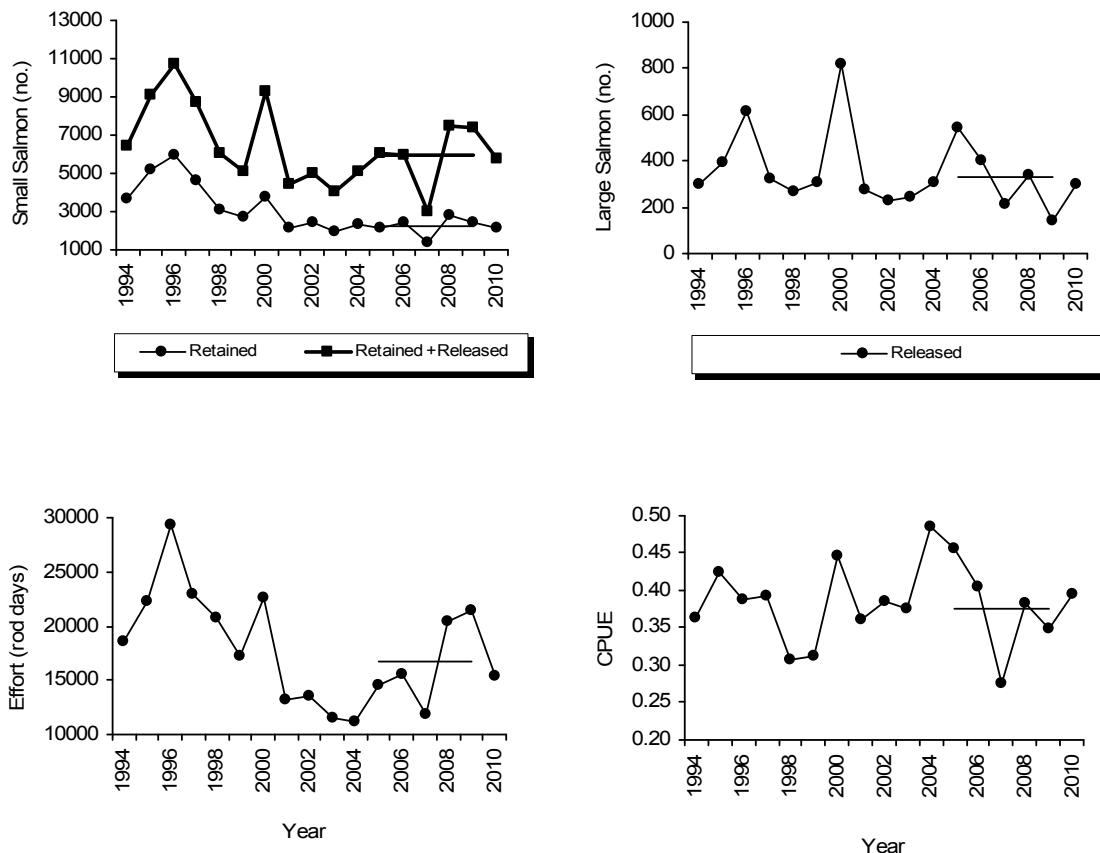

Figure 6. Recreational catch of small and large salmon, effort, and catch per unit of effort (CPUE), 1994–2010 for South (SFAs 9 – 11). Horizontal lines represent the previous generation mean, 2005–2009.

Southwest (SFAs 12 – 13)

Recreational Fishery

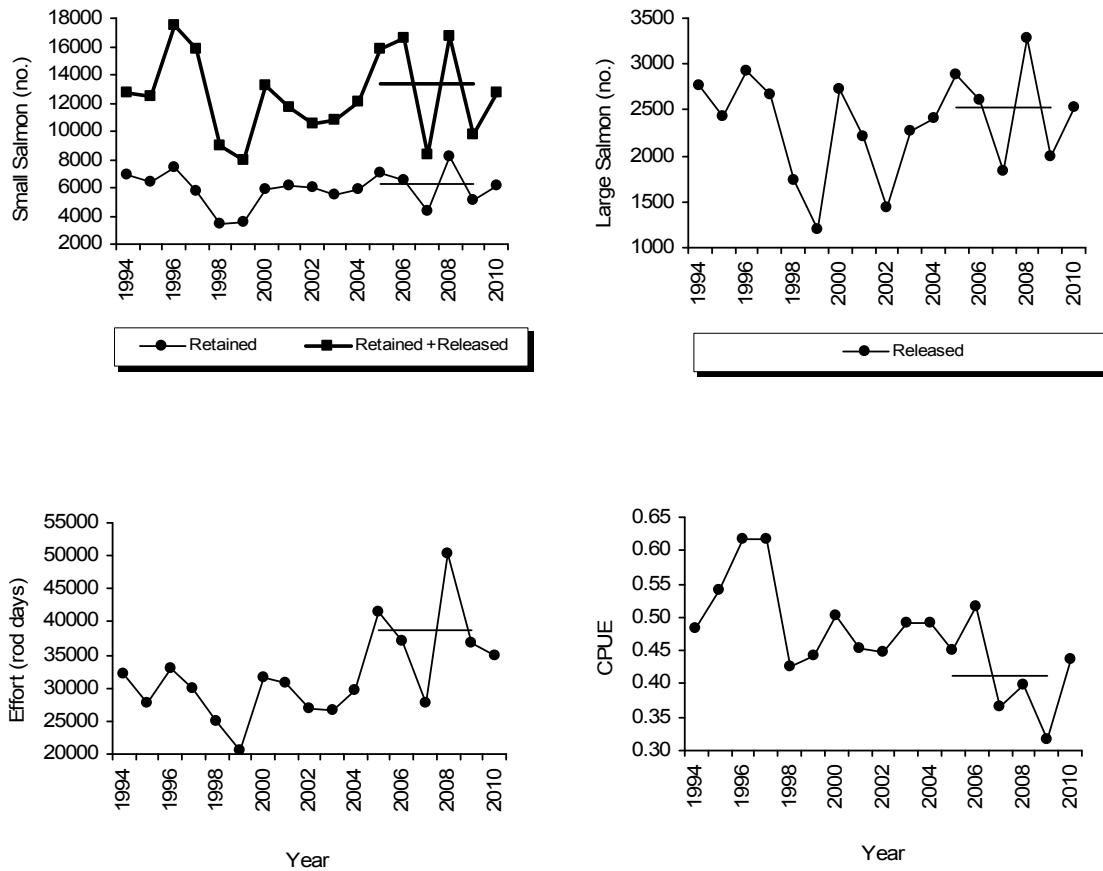

Figure 7. Recreational catch of small and large salmon, effort, and catch per unit of effort (CPUE), 1994–2010 for Southwest (SFAs 12 – 13). Horizontal lines represent the previous generation mean, 2005–2009.

Northern Peninsula West (SFA 14A)

Recreational Fishery

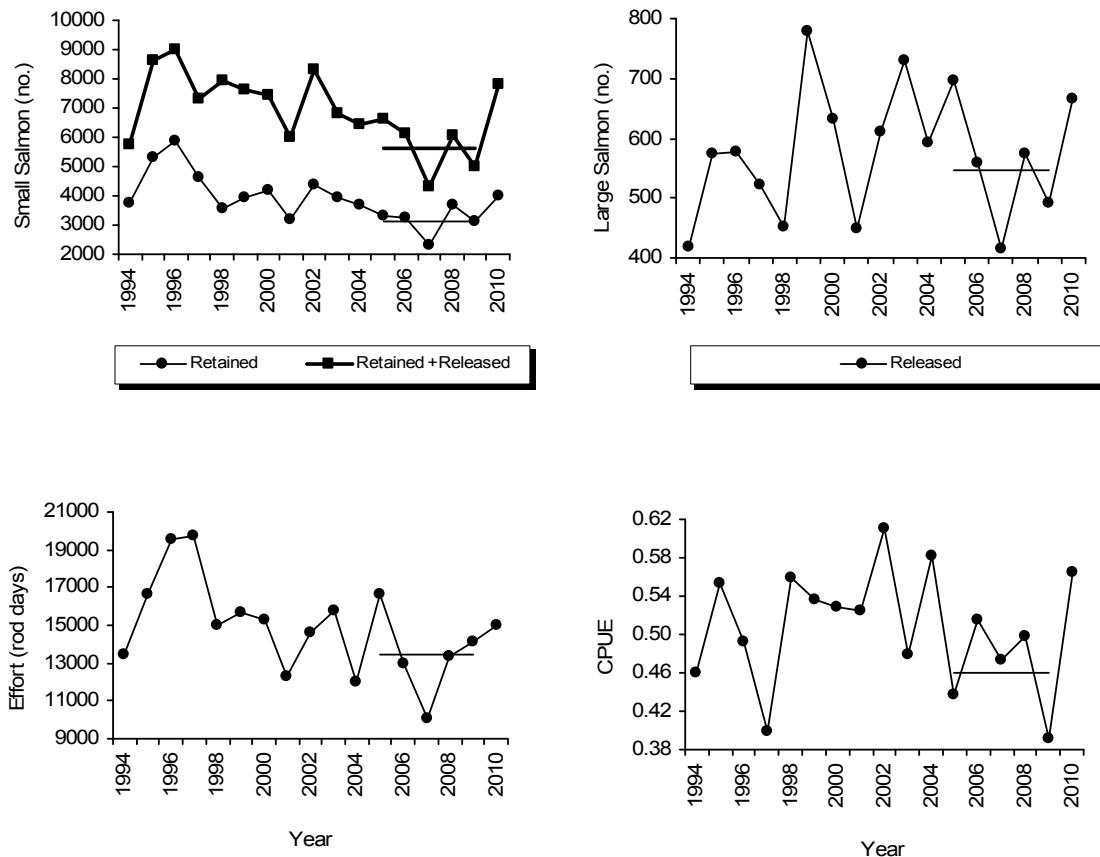

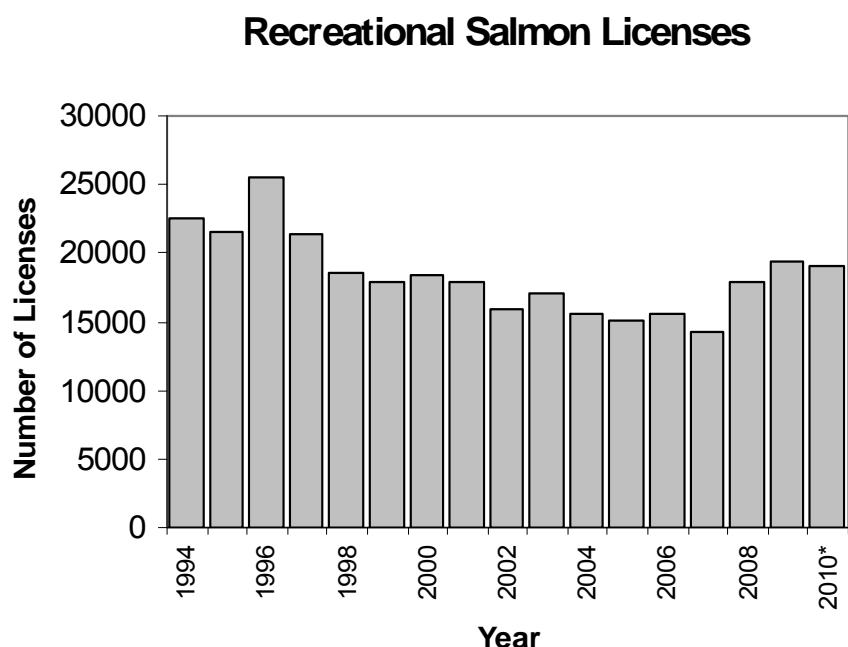

Figure 8. Recreational catch of small and large salmon, effort, and catch per unit of effort (CPUE), 1994-2010 for Northern Peninsula West (SFA 14A). Horizontal lines represent the previous generation mean, 2005-2009.

*Figure 9. Number of recreational Atlantic salmon fishery licenses sold from 1994 – 2010 (*preliminary).*

Marine Survival – Smolt to Adult

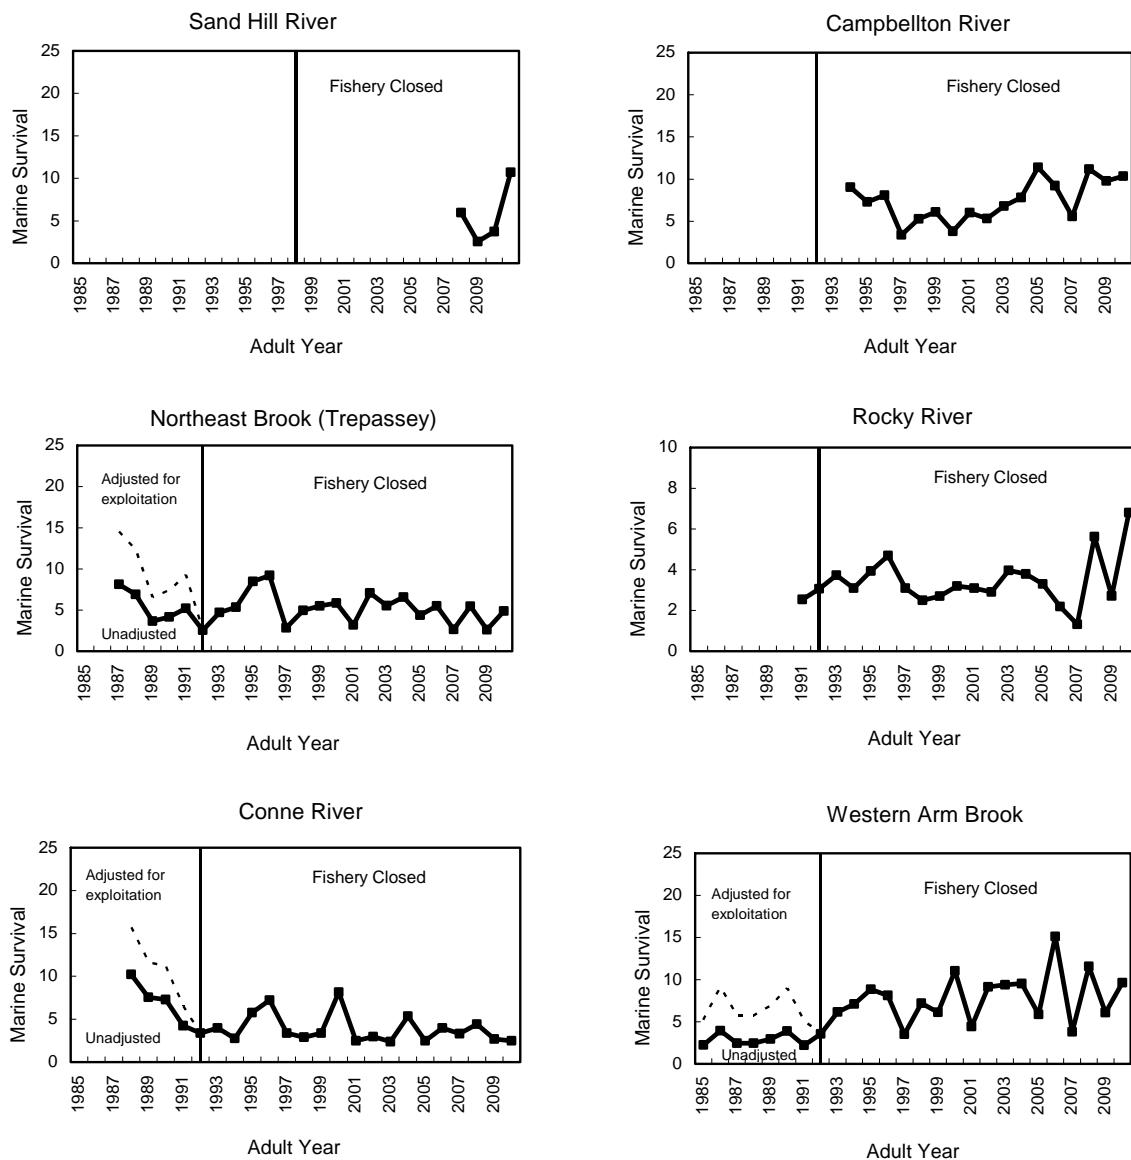

Figure 10. Marine survival (%) of smolts to adults (small salmon). Dashed line represents marine survival adjusted for average marine exploitation rate (Dempson et al. 1998).

Labrador (SFAs 1, 2 & 14B)

Trends in Abundance 1994-2010

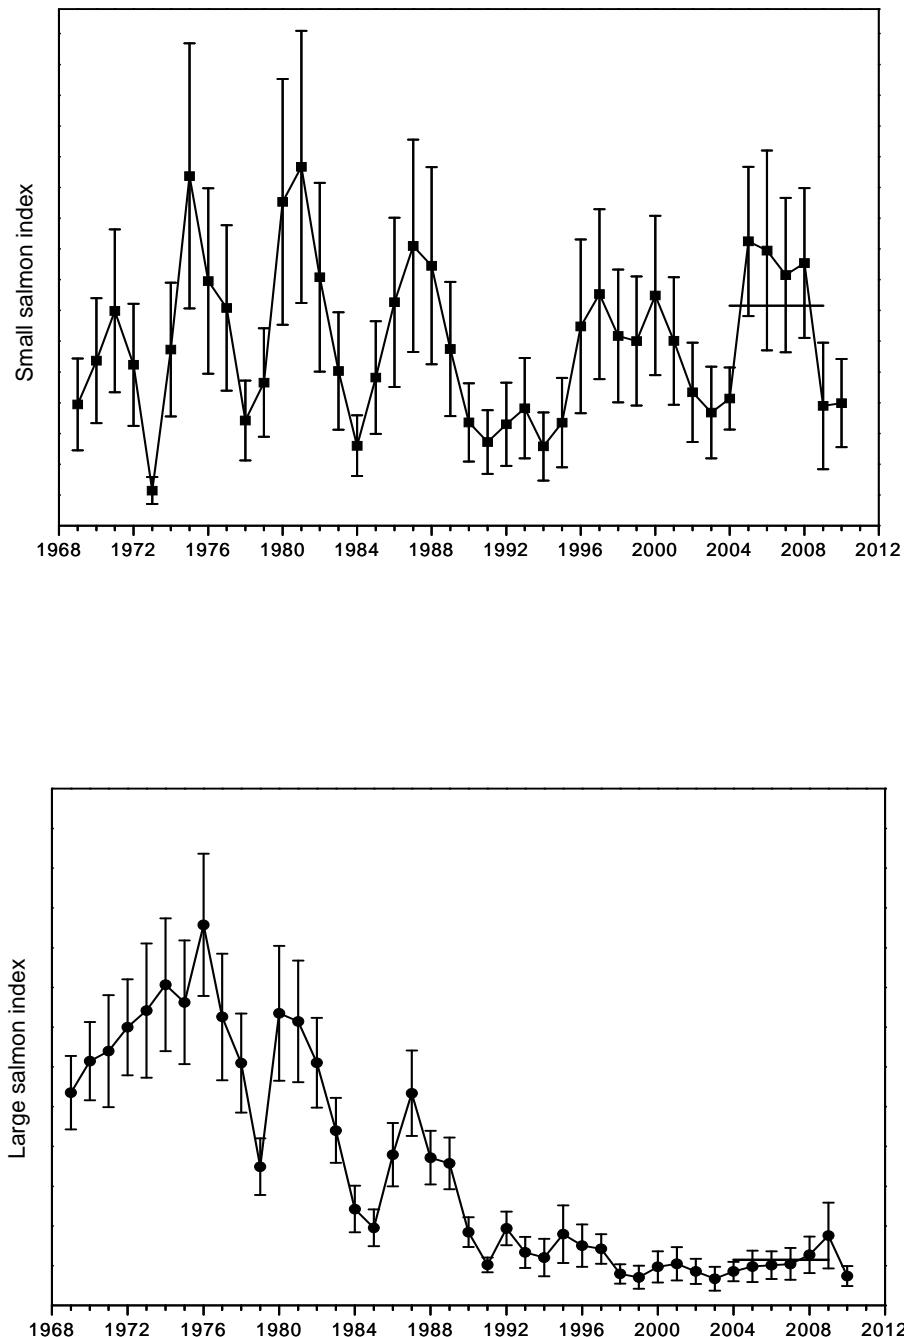

Figure 11. Trends in abundance of small and large salmon for Labrador (SFAs 1,2 & 14B), all rivers combined, from 1968-2010. Horizontal lines illustrate the mean abundance index for the previous six years 2004-2009. Vertical lines represent ± 1 standard error.

Insular Newfoundland (SFAs 3 – 14A)

Trends in Abundance 1984-2010

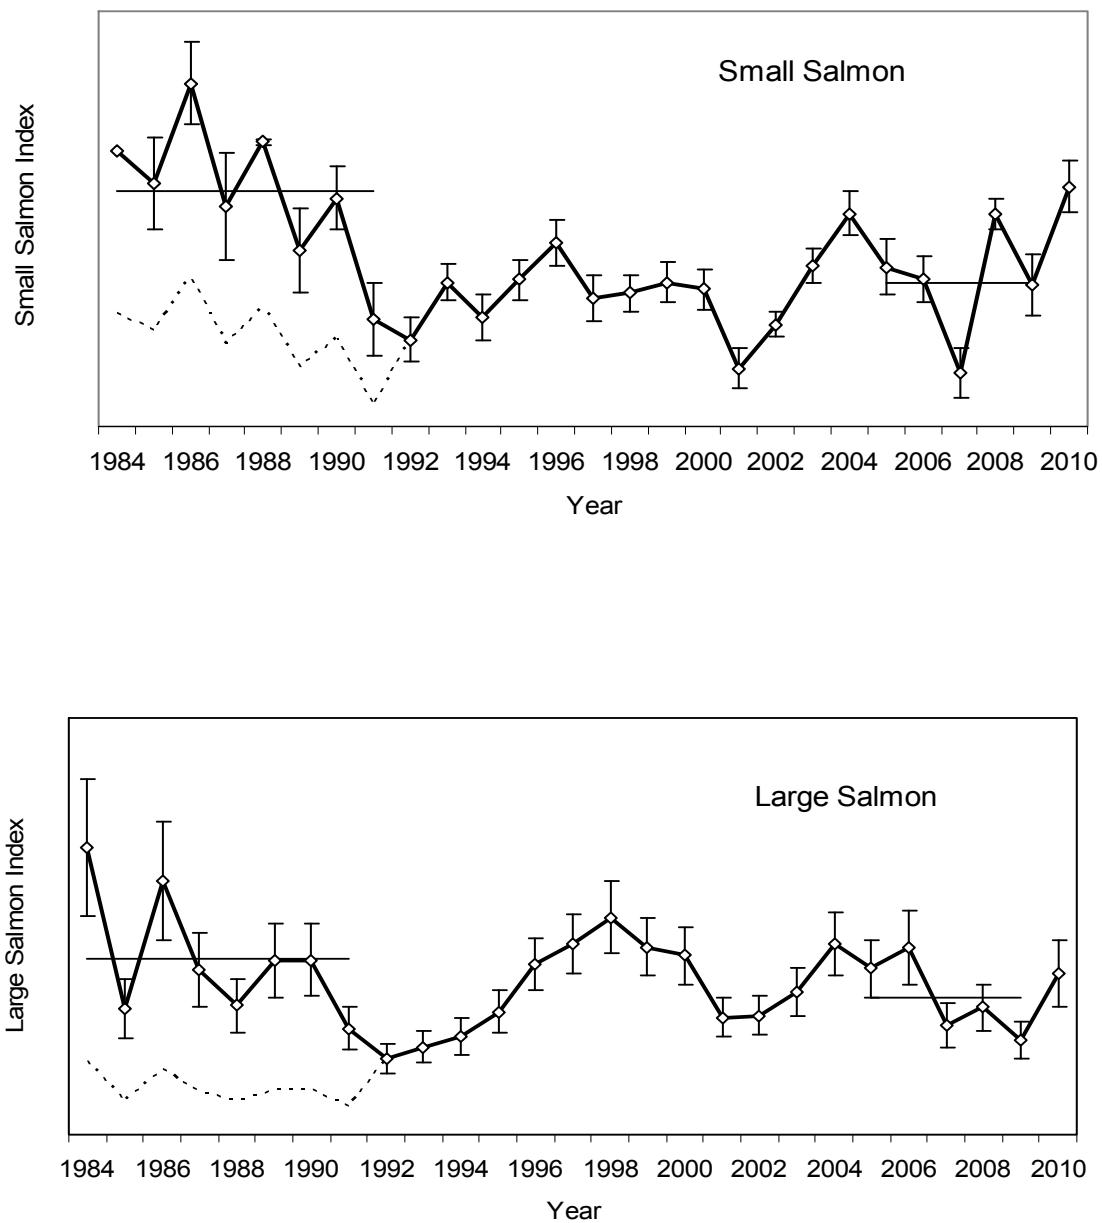

Figure 12. Trends in abundance of small and large salmon for Insular Newfoundland (SFA 3-14A), all rivers combined, from 1984-2010. Horizontal lines illustrate the mean abundance index for the periods 1984-1991, 1992-1996 and 1997-2009. Vertical lines represent ± 1 standard error. Dashed line represents returns unadjusted for marine exploitation for the period 1984-1991.

Labrador

Total Returns

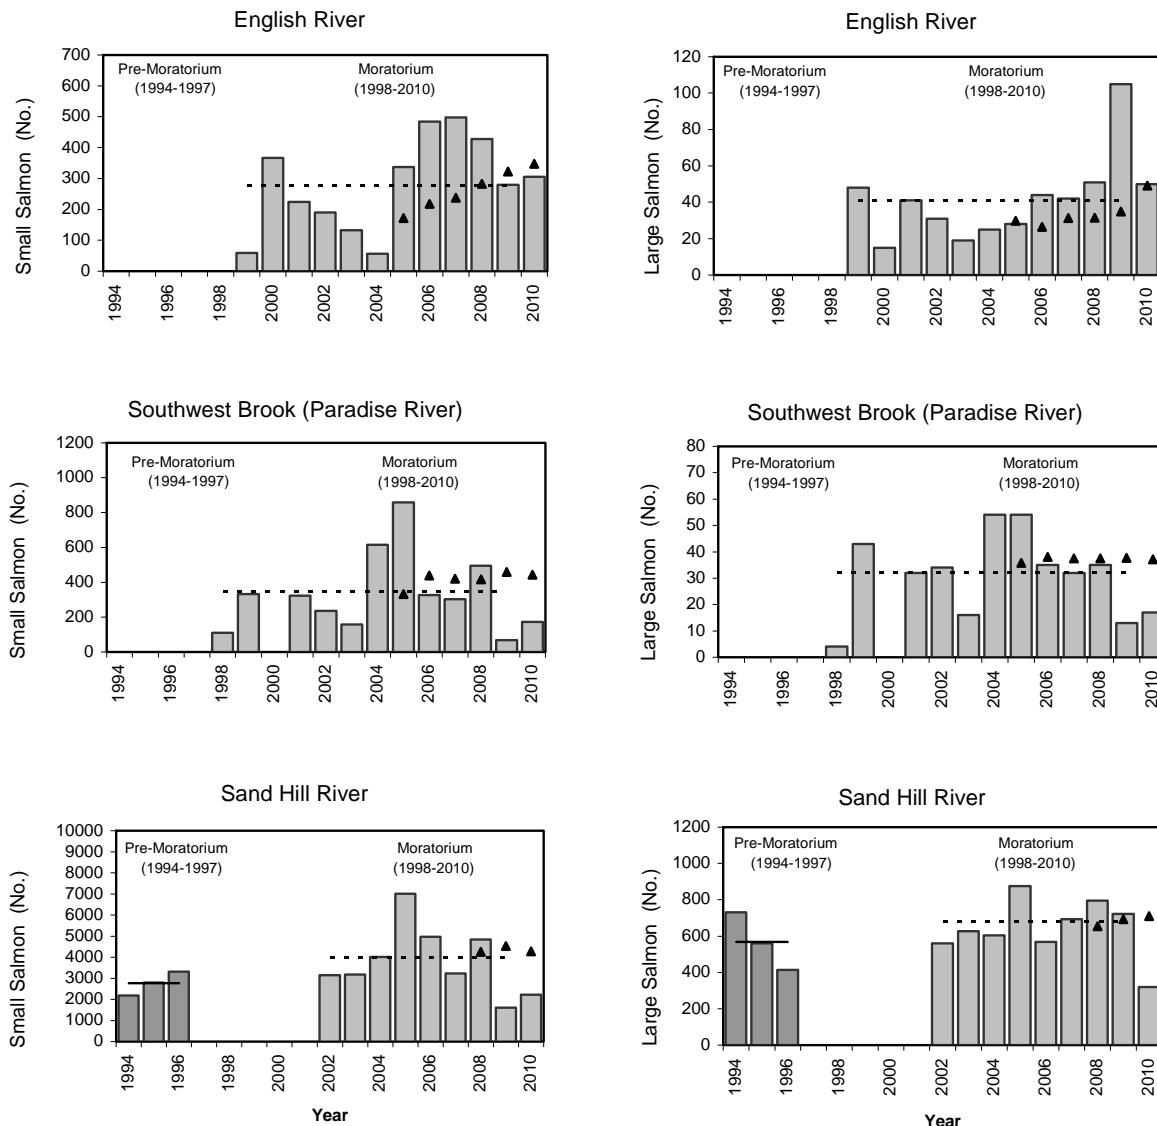

Figure 13. Total returns of small and large salmon to English River, Southwest Brook (Paradise River), and Sand Hill River, Labrador, 1994-2010. The solid horizontal line represents the pre-moratorium mean, the broken line the moratorium mean and the triangles represent the 6 year mean previous to each year. The dark gray bars are the pre-moratorium years and the lighter gray bars the moratorium years.

Labrador

Proportion Large Salmon in Total Returns

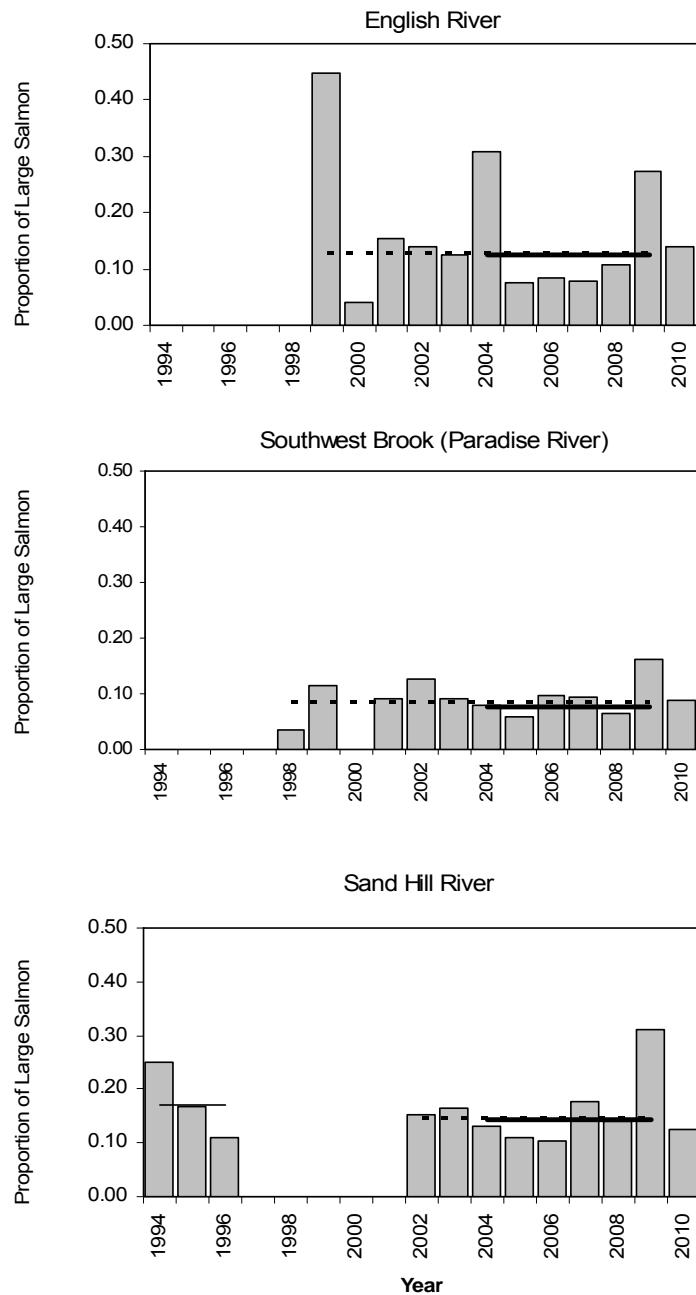

Figure 14. Proportion of large salmon in total returns to English River, Southwest Brook (Paradise River), and Sand Hill River, Labrador, 1994-2010. The thin solid horizontal line represents the pre-moratorium mean, the broken line the moratorium mean and the thick solid line the previous 6 year mean.

Insular Newfoundland - Northeast Coast

Total Returns

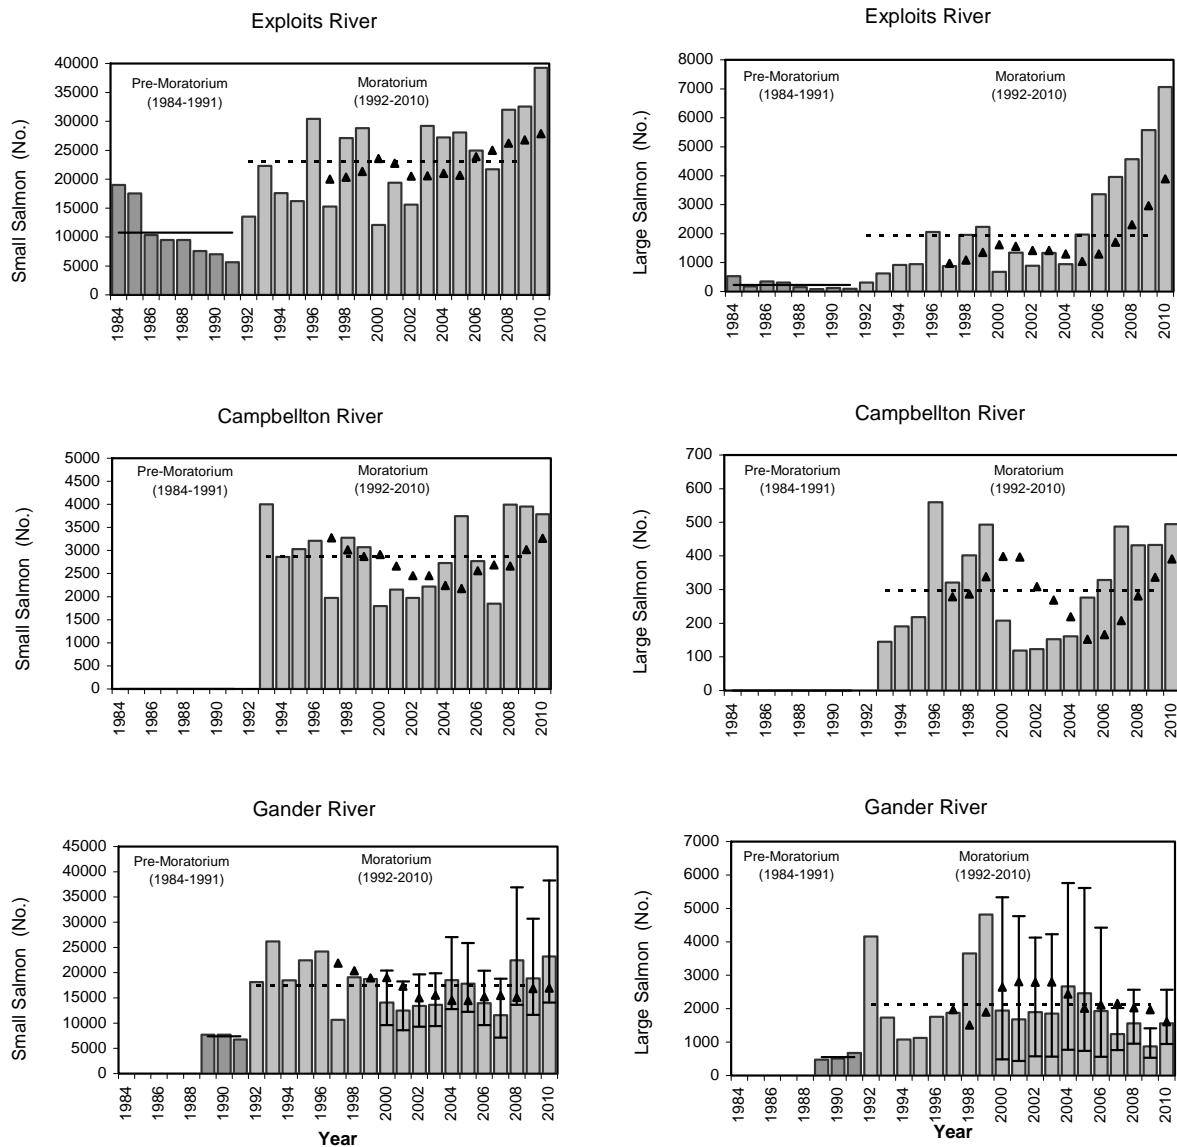

Figure 15. Total returns of small and large salmon to Exploits River, Campbellton River and Gander River, northeast coast Insular Newfoundland, 1984-2010. The horizontal solid line represents the pre-moratorium mean 1984-1991, the dotted line the moratorium mean 1992-2009 and the triangles the 5 year mean previous to each year. The dark gray bars are the pre-moratorium years and the lighter gray bars the moratorium years.

Insular Newfoundland - Northeast Coast

Proportion Large Salmon in Total Returns

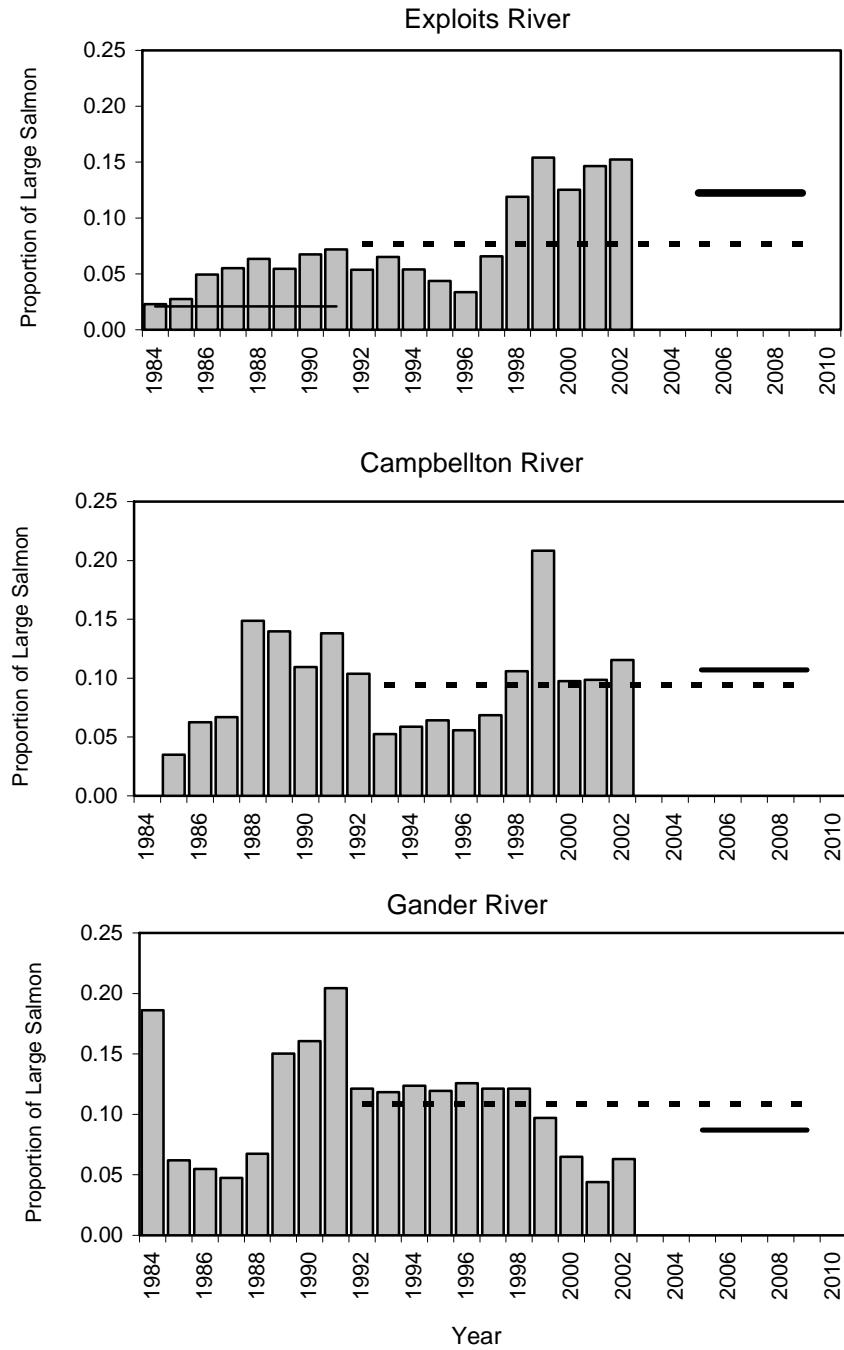

Figure 16. Proportion of large salmon in total returns to Exploits River, Campbellton River, and Gander River, northeast coast Insular Newfoundland, 1984-2010. The thin solid horizontal line represents the pre-moratorium mean 1984-1991, the broken line the moratorium mean 1992-2009 and the thick solid line the previous 5 year mean, 2005-2009.

Insular Newfoundland - East Coast

Total Returns

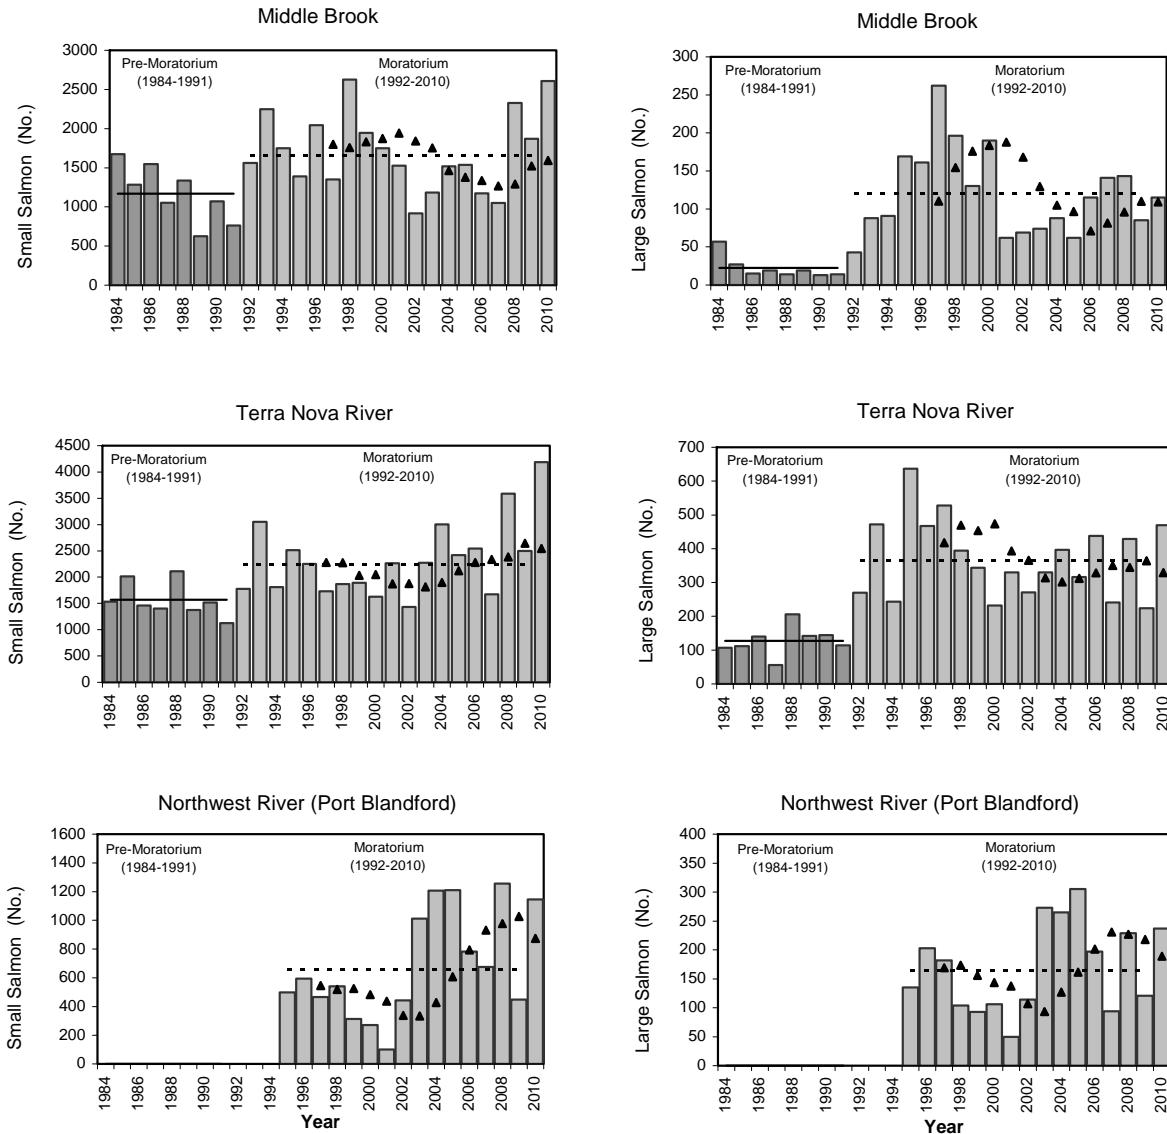

Figure 17. Total returns of small and large salmon to Middle Brook, Terra Nova River and Northwest River (Port Blandford), east coast Insular Newfoundland, 1984-2010. The horizontal solid line represents the pre-moratorium mean 1984-1991, the dotted line the moratorium mean 1992-2009 and the triangles the 5 year mean previous to each year. The dark gray bars are the pre-moratorium years and the lighter gray bars the moratorium years.

Insular Newfoundland - East Coast

Proportion Large Salmon in Total Returns

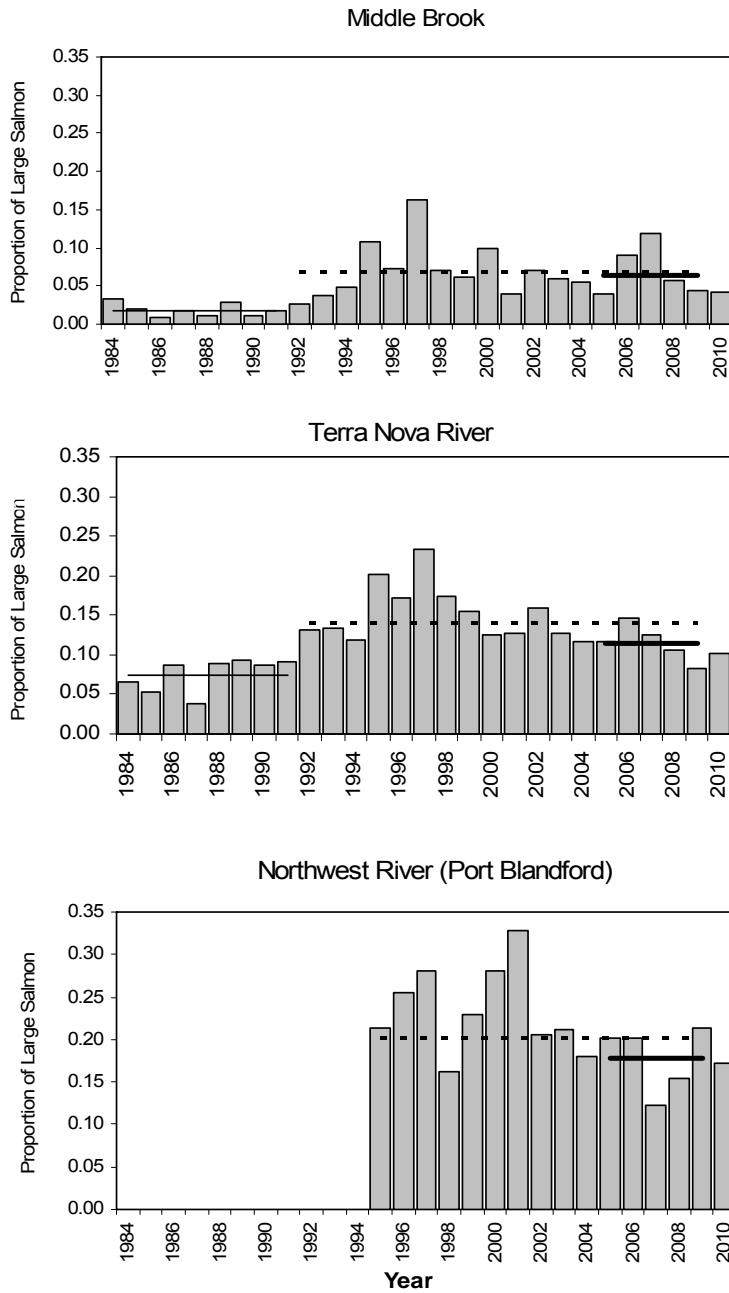

Figure 18. Proportion of large salmon in total returns to Middle Brook, Terra Nova River, and Northwest River (Port Blandford), east coast Insular Newfoundland, 1984-2010. The thin solid horizontal line represents the pre-moratorium mean 1984-1991, the broken line the moratorium mean 1992-2009 and the thick solid line the previous 5 year mean, 2005-2009.

Insular Newfoundland - South Coast

Total Returns

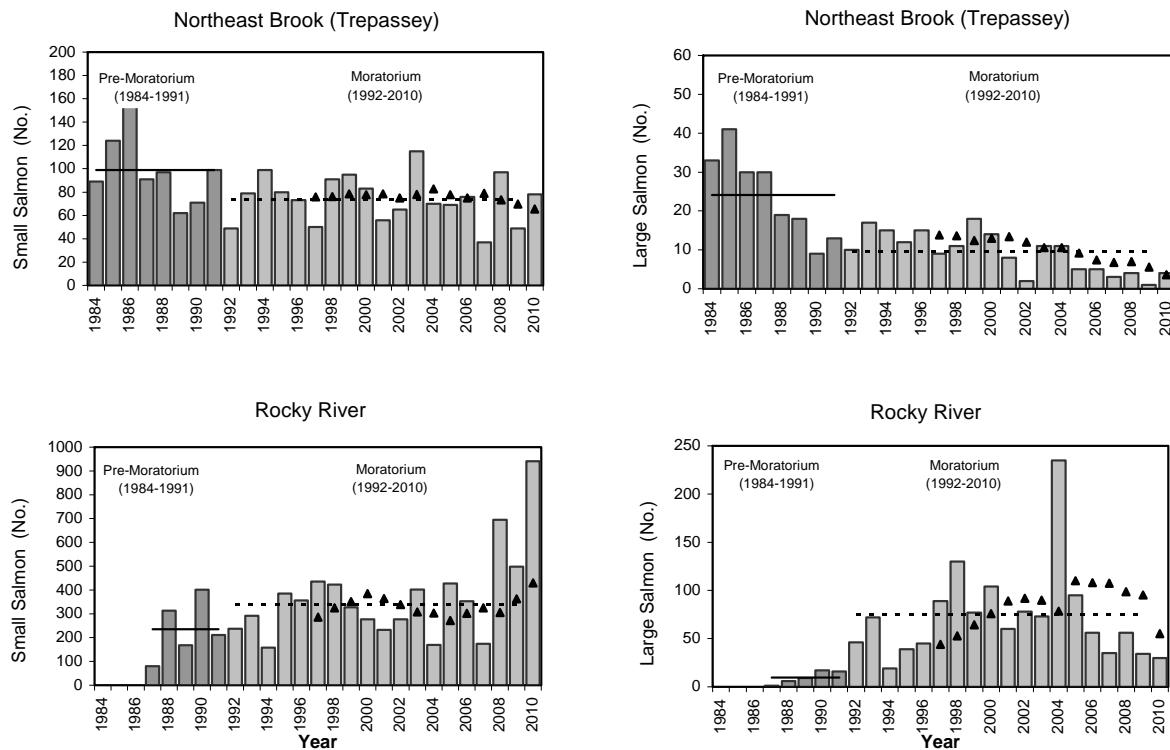

Figure 19. Total returns of small and large salmon to Northeast Brook (Trepassey), and Rocky River, South coast Insular Newfoundland, 1984-2010. The horizontal solid line represents the pre-moratorium mean 1984-1991, the dotted line the moratorium mean 1992-2009 and the triangles the 5 year mean previous to each year. The dark gray bars are the pre-moratorium years and the lighter gray bars the moratorium years.

Insular Newfoundland - South Coast

Total Returns

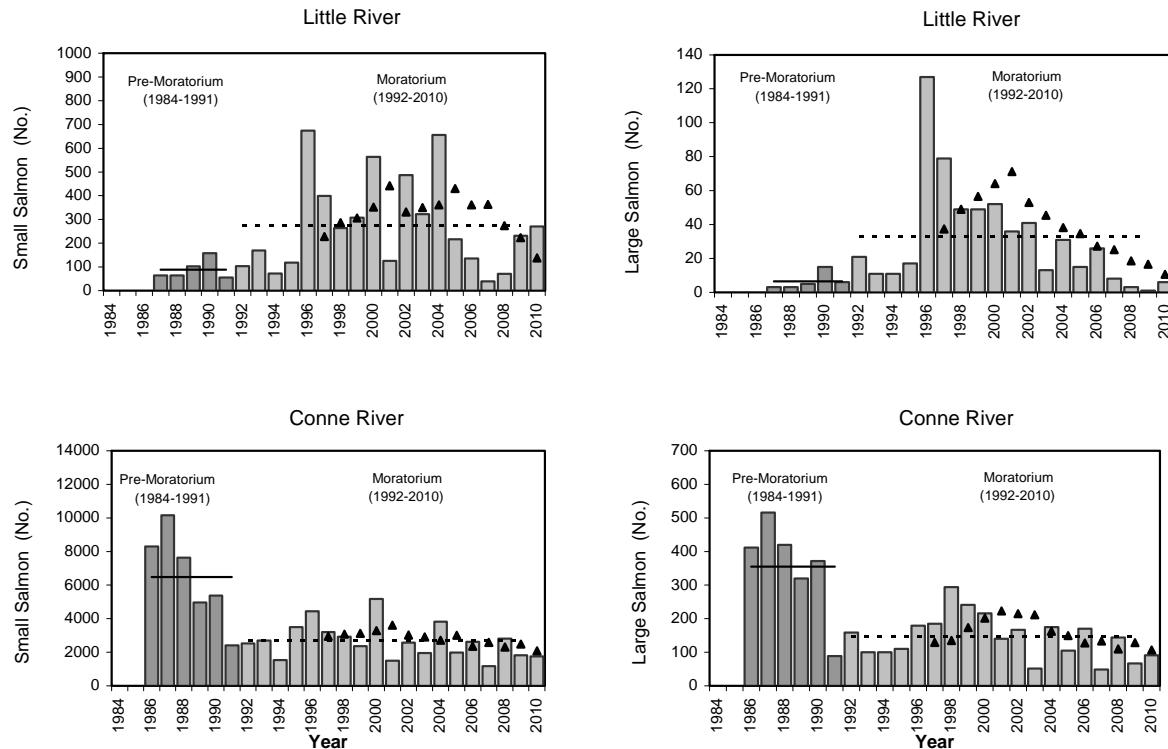

Figure 19 (cont'd). Total returns of small and large salmon to Northeast Brook (Trepassey), and Rocky River, South coast Insular Newfoundland, 1984-2010. The horizontal solid line represents the pre-moratorium mean 1984-1991, the dotted line the moratorium mean 1992-2009 and the triangles the 5 year mean previous to each year. The dark gray bars are the pre-moratorium years and the lighter gray bars the moratorium years.

Insular Newfoundland - South Coast

Proportion Large Salmon in Total Returns

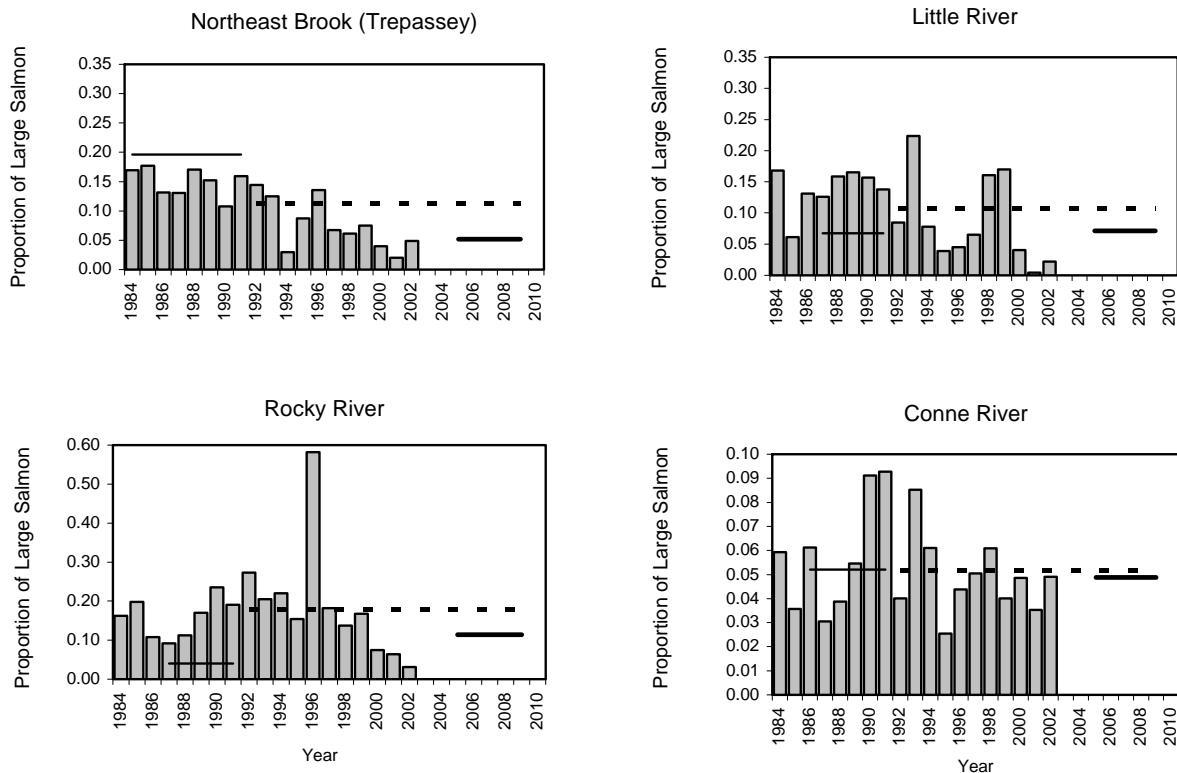

Figure 20. Proportion of large salmon in total returns to Northeast Brook (Trepassey), Rocky River, Little River and Conne River, South coast Insular Newfoundland, 1984-2010. The thin solid horizontal line represents the pre-moratorium mean 1984-1991, the broken line the moratorium mean 1992-2009 and the thick solid line the previous 5 year mean, 2005-2009.

Insular Newfoundland - Southwest & Northwest Coasts

Total Returns

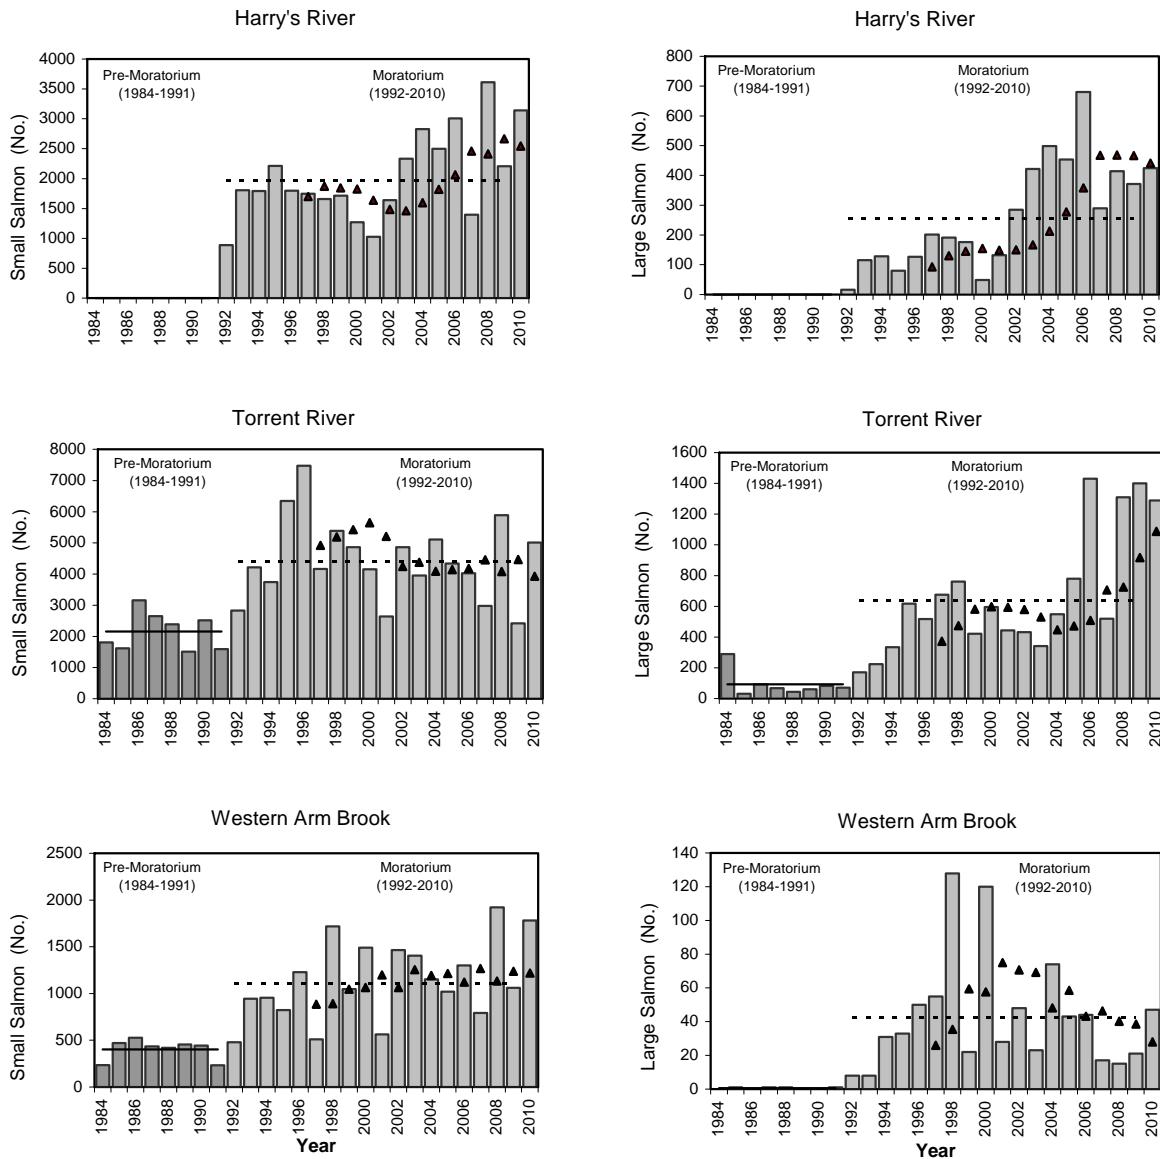

Figure 21. Total returns of small and large salmon to Harry's River (southwest coast), Torrent River and Western Arm Brook (northwest coast), Insular Newfoundland, 1984-2010. The horizontal solid line represents the pre-moratorium mean 1984-1991, the dotted line the moratorium mean 1992-2009 and the triangles the 5 year mean previous to each year. The dark gray bars are the pre-moratorium years and the lighter gray bars the moratorium years.

Insular Newfoundland – Southwest & Northwest Coasts

Proportion Large Salmon in Total Returns

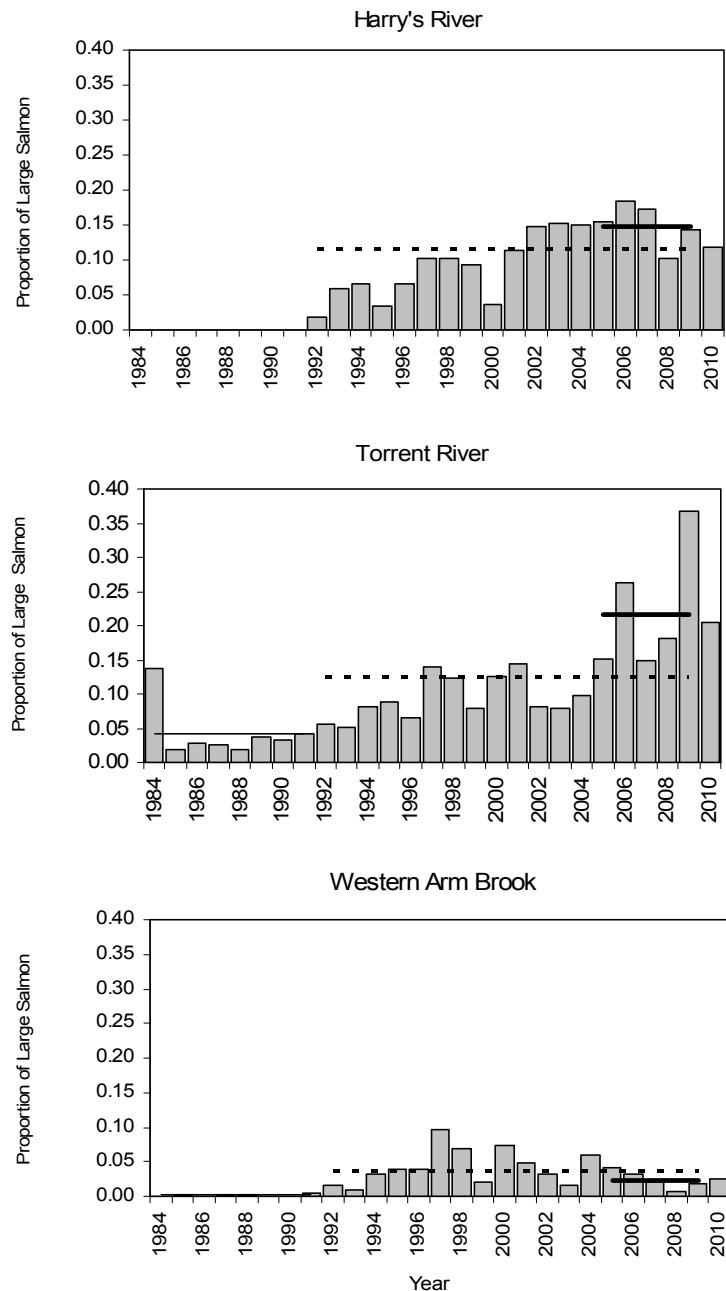

Figure 22. Proportion of large salmon in total returns to Harry's River (southwest coast), Torrent River and Western Arm Brook (northwest coast), Insular Newfoundland, 1984-2010. The thin solid horizontal line represents the pre-moratorium mean 1984-1991, the broken line the moratorium mean 1992-2009 and the thick solid line the previous 5 year mean, 2005-2009.

Labrador

Conservation Requirement Achieved 1994-2010

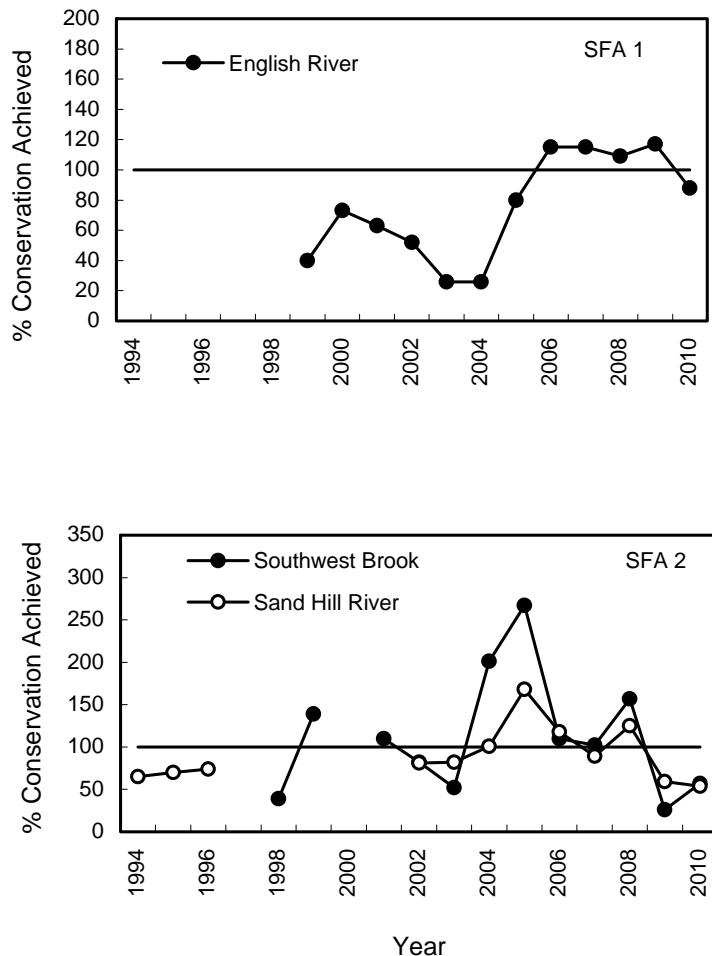

Figure 23. Percentage of conservation requirement achieved from 1994-2010 for rivers In Labrador by SFA (Salmon Fishing Area). The horizontal line represents 100% conservation requirement.

Insular Newfoundland

Conservation Requirement Achieved 1984-2010

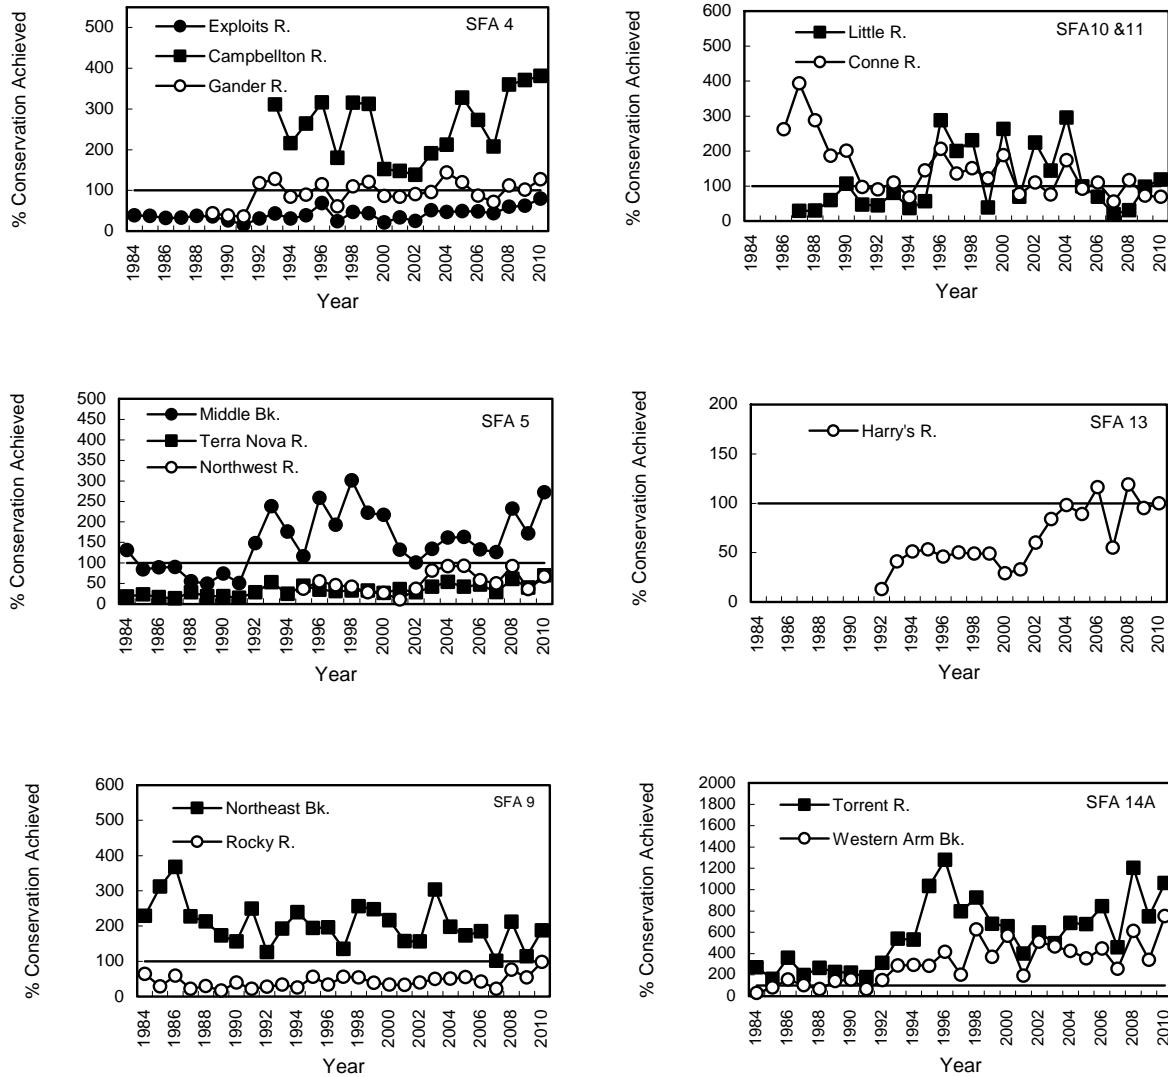

Figure 24. Percentage of conservation requirement achieved from 1984-2010 for rivers in insular Newfoundland by SFA (Salmon Fishing Area). The horizontal line represents 100% conservation requirement.
