ABSTRACT

Sandstrom, S. J., P. J. Lemieux, and J. D. Reist. 1997. Enumeration and biological data from the upstream migration of Dolly Varden charr (Salvelinus malma) (W.), from the Babbage River, Yukon north slope, 1990 to 1992. Can. Data Rep. Fish. Aquat. Sci. 1018: iv + 132 p.

In 1990, 1991, and 1992 an assessment project (using a floating deflection-board weir) was conducted on the anadromous Dolly Varden charr stock in the Babbage River to establish its overall abundance and composition. A summary of the dates on which the weir was in operation in 1990, 1991, and 1992 and the number of charr counted, live sampled, dead sampled, and tagged in each of those years are presented. Weir counts were 7274, 5170, and 4114 fish for 1990, 1991, and 1992, respectively. Summaries of length, weight, maturity, sex and age data for the three sample years are presented. Annual growth rates from Floy-tagged recaptured individuals are also presented. An estimate of the size and instantaneous mortality rate of the anadromous component of the stock was calculated using the Floy-tag recapture data and Bailey's Triple Mark Recapture Procedure. This procedure, when controlled for tag loss, estimated the size and mortality rate of the anadromous stock at 13,639 ± 3024 and 27.6%. A detailed discussion of construction details for the floating deflection weir is provided along with recommendations for improvements to the design. A complete copy of the raw data collected by the project is included.

Key words: Dolly Varden; Salvelinus malma; weirs; enumeration; population dynamics; growth; anadromous species; tagging; spawning.

RÉSUMÉ

Sandstrom, S. J., P. J. Lemieux, and J. D. Reist. 1997. Enumeration and biological data from the upstream migration of Dolly Varden charr (Salvelinus malma) (W.), from the Babbage River, Yukon north slope, 1990 to 1992. Can. Data Rep. Fish. Aquat. Sci. 1018: iv + 132 p.

En 1990, 1991 et 1992, on a réalisé un projet d'évaluation (utilisant une barrière flottante avec déflecteur) du stock anadrome de Dolly Varden de la rivière Babbage pour établir son abondance et sa composition globaux. On présente un sommaire des dates d'utilisation de la barrière en 1990, 1991 et 1992 et du nombre de Dolly Varden dénombrés, échantillonnés vivants, échantillonnés morts et marqués dans chacune de ces années. On a compté 7 274, 5 170 et 4 114 poissons en 1990, 1991 et 1992 respectivement. On présente des sommaires des données de longueur, de poids, de maturité, de sexe et d'âge pour les trois années. On présente aussi les taux de croissance annuelle des individus recapturés portant des marques Floy. On a calculé une estimation de la taille et du taux de mortalité instantané de la composante anadrome du stock au moyen des données de recapture des poissons portant des marques Floy et de la méthode de calcul de Bailey. Cette méthode, une fois pris en compte les pertes de marques, nous a permis d'estimer la taille et le taux de mortalité du stock anadrome à 13 639 ± 3 024 et 27,6 %. On donne des renseignements détaillés sur les détails de construction de la barrière flottante avec déflecteur de même que des recommandations pour en améliorer la conception. L'ensemble des données brutes recueillies dans le cadre du projet est inclus.

Mots-clés : Dolly Varden; *Salvelinus malma*; barrières; dénombrement, dynamique des populations; croissance; espèce anadrome; marquage; fraye.

INTRODUCTION

The Yukon north slope and adjacent portions of the Northwest Territories have four river systems that support genetically discrete stocks of the northern form of Dolly Varden charr (*Salvelinus malma*)(Walbaum)(Reist 1989; Reist et. al. 1997). These rivers are the Rat, Big Fish, Babbage, and Firth (Fig. 1). Charr stocks in the Rat and Big Fish rivers have been subject to annual subsistence harvests, both historically and presently. Residents of Aklavik and Fort McPherson NT, utilize these resources extensively, primarily because of their proximity to these Mackenzie Delta communities. In contrast, in the Firth and Babbage Rivers, little or no harvesting of charr has taken place in recent years due to the distance of these systems from the settled areas (e.g., 230 km and 170 km, respectively). Up until the early 1970's, charr from these two stocks were probably taken in coastal fisheries at Herschel Island. At present, charr from both of these stocks are taken only by subsistence fisheries at Shingle and King Points, and perhaps by coastal fisheries in Alaska. The overall number harvested annually appears to be small (< 500) (L. Harwood, Department of Fisheries and Oceans, Inuvik, personal communication). In addition, approximately 100 charr are taken each summer by a small sports fishery on the Firth River (D. Frandsin, Parks Canada, Inuvik, personal communication).

The existence of unexploited and presumably stable Dolly Varden charr stocks provides an unique opportunity to investigate a stock close to its natural composition and abundance. Knowledge of the size, structure, and life history traits (e.g., growth and mortality rates, age-at-first maturation) of an unexploited stock, and the natural variability associated with these aspects could be used to provide managers with a 'baseline' with which to compare currently harvested stocks such as those in the Rat and Big Fish rivers. Such a comparison would allow for better long-term management of harvested stocks, by determining how the stocks might respond to various levels of fishing pressure. In addition, a more detailed understanding of how north slope Dolly Varden charr stocks operate both with and without a fishery, would allow managers to recommend safe harvest levels and predict recovery rates with more confidence. These aspects could be examined if an unexploited stock, whose size and composition was known, was exploited at a known rate and whose recovery was closely monitored. Such a study was planned for the Babbage River charr stock in the late-1980s, and in 1990, the first phase of the work was begun.

Between 1990-1992 the Department of Fisheries and Oceans (DFO) and the Fisheries Joint Management Committee (FJMC) undertook 'Phase One' of a proposed two-phase research project investigating the charr stock in the Babbage River. 'Phase One' of the research project was a three-year weir enumeration study to establish the size and structure of the anadromous component of the stock. The results from 'Phase One' are the subject of this report. 'Phase Two', not yet undertaken, was to conduct a controlled removal of a known portion of the stock and then to monitor the response of the stock to this level of exploitation.

The main goals of the first year (1990) of the study were to locate a suitable site for the weir, transport the materials to the site, construct and evaluate the effectiveness of the weir, and establish sampling protocols. Goals of the second and third years (1991 and 1992) were to establish stock size and composition. The three year study was completed in the fall of 1992, and this report provides a compilation of the physical and biological data collected during the upstream enumeration of the Dolly Varden charr stock in the Babbage River (1990, 1991 and 1992).

STUDY AREA

Babbage River

The Babbage River (Fig.1) originates in the British Mountains at an elevation of 610 m. From its headwaters, the river flows a distance of 137 km to its mouth at Phillips Bay on the Beaufort Sea coast, draining an area of approximately 1 510 km^2 (Bain 1974). The overall slope of the river is 4.5 m/km and has a total annual discharge of 343,000 1000m^3 (based on a nine year average; Department of Inland Waters, unpublished data).

The upper main channel of the Babbage River is shallow and flows over mixed gravel and rock, until it enters the coastal plain, where the channel deepens and begins to meander. In this region, the gravel streambed is covered by a deep layer of mud and silt. Summer flow in the main channel of the Babbage River depends upon snowmelt, precipitation and groundwater upwellings. Except during the spring freshet, the water of the upper Babbage River remains clear throughout the open water season; the lower river is generally more turbid due to the shale, fluviatile and glacial deposits in the lower Babbage River Valley. The entire lower Babbage River is frozen over during the winter and in most places the ice is grounded to the river bed.

Canoe River, a tributary of the Babbage River, is used by both the anadromous and freshwater life history forms of the stock for spawning, rearing and overwintering. Canoe River flows a distance of approximately 24 km from it's origin at the junction of Fish Hole Creek and Wood Creek (elevation 250 m) and enters the Babbage River approximately 60 km downstream of the Babbage headwaters. Canoe River consists of alternating pools and riffles with a shale-gravel substrate, and flows only during the ice-free season. Freshwater thermal springs occur in both Wood Creek and Fish Hole Creek at approximately 40 m upstream of their confluence with Canoe River. The presence of these springs maintains a 1.5 km section of unfrozen water in Canoe River throughout the winter, known locally as 'Fish Hole'. It is thought that this habitat associated with the springs is utilized by all charr (including residual males) of the Babbage River charr stock for spawning, and overwintering. In addition, this area as well as other sections of the Babbage River Drainage Basin are used during the summer by juvenile charr for rearing. At the downstream limit of the 'Fish Hole', a large *Aufeis* (layered ice) field forms during the winter. The low mineral content and temperature (4° C) of the spring water indicates that its movement through the ground, from the area where surface water first enters (recharge site) to where it upwells near the junction of Wood and Fish Hole Creek, is shallow and rapid (Mutch and McCart 1974). The recharge area for the spring is probably the high ground to the southeast where water can enter the limestone formation.

Fish species composition

Two fish species predominate in the Babbage River Drainage Basin. These are the Dolly Varden charr and Arctic grayling (*Thymallus arcticus*)(Pallas). The Dolly Varden charr has both an anadromous and co-occurring non-anadromous form (termed residual), whereas the Arctic grayling is strictly a freshwater species. Grayling also utilize the headwater spring on Canoe River for overwintering but spawn in late-June in lower tributaries of the Babbage River. Broad whitefish (*Coregonus nasus*), and northern pike (*Esox lucius*) are found incidentally in the river as well.

The Babbage River also supports an isolated stream-resident stock of Dolly Varden charr, found associated with springs above the waterfall on the mainstem of the river (Fig. 1). This stock is resident (i.e., does not undertake anadromous migrations) and is believed to be genetically distinct from the

anadromous and residual charr found downstream (Reist 1989).

MATERIAL AND METHODS

WEIR DESIGN

A floating deflection-board weir, adapted from a design used in Alaska, was used to enumerate the anadromous component of the Babbage River charr stock during the three year study. Previous attempts to use fixed metal conduit weirs (as described in Kristofferson et al. 1986) on other north slope rivers were unsuccessful (Gillman and Sparling 1985; MacDonell 1987; Fehr and Archie 1989). The north slope rivers, including the Babbage River, are rapid runoff rivers, with water levels which rise quickly after a rainfall. In earlier studies, high water velocities and accumulation of debris on the weir after a rain often led to a partial or complete collapse of the fixed weir. The main advantage of the floating deflection-board weir over the fixed design is that, at times of excessive discharge from the river, the weir becomes temporarily submerged. This in turn relieves the pressure and allows debris to pass. When flows recede, the weir floats back to the surface and resumes its function of blocking the movement of fish migrating upstream.

WEIR SITE SELECTION

The site selected for installation of the weir is located approximately 70 km from the coast, and several hundred meters downstream of the confluence of Caribou Creek with the mainstem of the Babbage River (latitude: 68° 50' 22" North, longitude: 138° 40' 05" West) (Fig. 1). This site was selected because it had a gravel bar large enough on which to safely land a Twin Otter, and because the river's profile and bottom substrate at this site was determined to be suitable for weir construction and operation (Department of Inland Waters, unpublished data).

The criteria for an appropriate site for the installation of a deflection-board weir are: 1) the bottom profile of the stream must be straight so that the channel iron can lie relatively flat; 2) maximum water depth should not exceed 1.5 meters; 3) current velocity should not exceed 1.5 m/sec for any extended period of time; and, 4) bottom substrate should be predominantly gravel or cobble to avoid washout below the deflection boards and sedimentation below the panels upstream of the deflection boards.

WEIR CONSTRUCTION

The basic construction details for the floating deflection-board weir at the Babbage River were as follows:

1) a length of 10.2 cm wide channel iron, which spanned the width of the river to within three to four meters of each bank, was aligned perpendicular to the flow of the river. This was secured to the river bottom by duck bill anchors driven into the substrate every 3.05 m (Fig. 2). These were attached to the channel with 0.3 cm cables which had in-line ratchets to adjust the tension of the cable. The channel was also anchored by 1.5 meter long cold-rolled steel rods (1.2 cm diameter) driven through every second stabilizing flange (Fig. 2). A wire cable clamp was attached to the rod near the flange to anchor the two together. The flanges were bolted to the bottom of the channel iron at 1.37 meter intervals.

2) Attached to the top and running the length of the channel iron was a 1.0 cm diameter galvanized steel cable. This was anchored at one end of the channel iron with a duckbill anchor and tightened at the other to a tension of 680 kilograms using a 1000 kilogram cable puller. Four large wire cable clamps were used to secure this end to the channel iron. The cable was held in line with the channel iron by eye bolts bolted on the top and downstream edge of the channel iron at 0.6 meter intervals. In one of the initial sections of channel iron welded chainlinks were used instead of eye bolts. A row of sandbags was placed on either side of the channel iron to prevent the substrate beneath the channel from washing out.

3) The bottom edge of each PVC (polyvinyl chloride) conduit panel was then hooked side by side to this cable. Each panel was 120.7 cm (bottom edge) by 4.57 m and was made up of twenty four 4.57 m lengths of PVC conduit (either 3.8 cm or 2.5 cm in diameter) mounted on five wooden (fir) cross members (5.1 cm x 4.5 cm x 120.7 cm) and one wooden base plate (5.1 cm x 10.2 cm x 120.7 cm) (Fig. 3). Two hooks made out of 1.0 cm diameter threaded ready rod were attached to the base plate. The plate was strengthened along the bottom and underside edge by two 120.7 cm lengths of flat bar welded at right angles. This was held to the wooden base plate by the ready rod hooks. Each PVC conduit was glued and capped at both ends to make it water tight and secured to the base plate and each cross member with PVC strapping. The spacing between the conduit was 1.5 cms and this was based on the interorbital width of the smallest recorded searun charr from the north slope (Reist, unpublished data). Adjoining panels were fastened to each other by a single 4.57 m x 3.8 cm uncapped PVC conduit which passed through 3.8 cm rings (cut from steel piping) attached to the ends of each of the panel's five cross members (Fig. 3). A 120.7 cm by 61.0 cm deflection board (5.1 cm thick blue styrofoam sandwiched between two sheets of 0.64 cm plywood) was attached to the last downstream cross member on the underside of each panel with aluminum hinges. All wood used to construct the weir was painted with two coats of marine enamel. The deflection board was held at the appropriate angle by two 0.3 cm diameter cables on the underside of each panel.

4) A trap to collect and hold the fish was located at the end of the floating weir some distance (2.4 m to 6.1 m) upstream of the channel iron. This was connected to the floating weir by way of a short length of fixed weir running at a 45° angle away from the mouth of the trap. The fixed weir was assembled as outlined in Kristofferson et al. (1986). Lengths of fixed weir were also used to block off the area of river between each end of the floating weir and the river bank.

Three different configurations of the weir were used over the three years of the study. In the first year of the project (1990), 23 panels of 3.8 cm diameter PVC conduit were built. The remainder of the 53 m wide river was blocked off using 27.4 m of fixed weir oriented at a 45° angle between the shore (downstream of the weir) and the east side of the floating section of weir (Fig. 4). In 1990, the trap was located approximately 16.8 m from the east shore of the river. In the 1991 and 1992 enumerations, 14 panels of 2.5 cm diameter PVC conduit were added to the 23 panels PVC conduit used in 1990. In 1991 (Fig. 5) and 1992 (Fig. 6) the trap was moved to the west side of the river, where it was approximately 1.8 m from the river bank. The trap was placed approximately 2.4 meters upstream of the floating weir in 1991 and 6.1 meters in 1992. In 1991 and 1992 the material used for the trap walls was changed from a 2.5 cm wire screen (used in 1990) to metal conduit, as the wire screen was found to damage the kypes of the large spawning males. In 1991 the wire screen trap was added to the east side of the floating weir with the mouth oriented upstream to catch any downstream migrating fish. This trap was not used in the summer of 1992 as it was found unnecessary during the 1991 enumeration.

Because the flow of the river was altered by both the presence and orientation of the weir, an assessment of charr behaviour in the vicinity of the weir was also conducted.

ASSESSMENT OF CHARR BEHAVIOUR NEAR THE WEIR

During each of the three summers that the weir was operating, large numbers of charr were seen during the daytime downstream of the weir. To investigate the length of time charr spent downstream of the weir prior to moving into the trap, some of these fish were captured by angling, Floy-tagged and released. Injury and stress to the fish were minimized by using heavy test line to reduce the time required to reel the fish in and barbless hooks to facilitate quick hook removal. In 1991, 53 charr were tagged and released and in 1992, 25 charr were tagged and released. In both years date of recapture was recorded, however, the date on which the fish was angled and tagged was only recorded in 1991. In addition to the charr angled and tagged, 12 charr in 1991 and 38 charr in 1992 were captured in the weir trap, tagged and released downstream of the weir.

On August 16, 1992 14 adult charr were tagged with external radio transmitters (365 day, 30 pulses per minute, 14 gm) and released downstream of the weir. Tagging was conducted to see whether charr that did not move upstream once they had encountered the weir were moving to neighbouring systems (e.g., Firth and Big Fish rivers) to overwinter (Sandstrom and Reist, unpublished data). Radio-tagged charr were also used to determine the specific location of overwintering habitat for those that remained in the Babbage River Drainage Basin. Radio-tagged charr captured in the trap were released downstream of the weir.

PHYSICAL DATA COLLECTION

Mean daily water temperatures were consistently recorded in 1991 and 1992. In 1991, daily water temperatures were recorded hourly with a Ryan Thermograph. In 1992, water temperatures were recorded during the trap checks using a hand-held mercury thermometer. Minimum and maximum air temperatures were recorded in 1991 and 1992 using a mercury-filled maximum/minimum thermometer, housed in a ventilated box. Staff gauge (water depth) readings were taken at each trap check in 1991 and 1992. The staff gauge consisted of a wooden meter stick anchored to a metal rod secured in the substrate near the trap. Average daily staff gauge readings was determined by taking a mean of all readings taken on a particular day.

BIOLOGICAL DATA COLLECTION

The trap was checked and emptied every day, at approximately 2-3 hr intervals between the hours of 18:00h and 06:00h. This was primarily the only time of day that the charr moved into the trap. The mouth of the trap funnel was blocked during each check to prevent any escape of charr downstream. All captured charr were removed from the trap using a long-handled scoop net. Charr were examined for tags or fin clips, and either enumerated and released upstream of the weir, or dead-sampled.

Live sample

In all years of the study, live-sampled charr were measured for fork length (± 1 mm), and if possible, were also sexed. In 1991 and 1992, a large proportion (36% and 71% respectively) of the live sample was also weighed (± 10 gm) before release. For weighing, fish were lightly anesthetized in a weak benzocaine solution (25 ppm) in one of two holding tubs. In 1991, fish were allowed to recover in the calm water between the trap and the west shore. In 1992, a holding pen, attached to the trap, with an exit hole at the upstream end, was used for this purpose.

In all years, a percentage of the live sample was also Floy-tagged (1990= 433 tagged, 1991= 669 tagged, 1992= 420 tagged). Tags were inserted at the base of the dorsal fin and anchored behind the basal pterygiophores. Floy-tagged fish that were recaptured in subsequent years allowed for calculation of annual growth, as follows: Annual Growth (mm) = ((length at recapture (mm) - length at tagging (mm)) ÷ (year recaptured - year tagged)).

An estimate of the size and instantaneous mortality rate of the 1991 anadromous charr stock was calculated using the tag recapture data and Bailey's deterministic model (Bailey 1951; see Appendix I and II).

Dead sample

In both 1990 and 1991, a dead sample stratified by length was collected ensuring that fish of all sizes were sampled each week. In 1990, no specific criteria were used to select fish, however, in 1991 approximately 5 fish per 50 mm size interval (300 to 600 mm) were dead sampled for a total of 30 fish per week. In 1992, a dead sample was collected with fish being randomly selected from the appropriate trap check. Dead-sampled charr were measured for fork length (± 1 mm) and round weight (± 10 gm), examined internally to determine sex, and assigned a maturity stage according to the following scale:

Life History Stage	Female	Male
Unknown	0	
Juvenile/Adult Non-spawner (silver)	1	6
Spawner (maturing)	2	7
Spawner (ripe)	3	8
Spawner (spent)	4	9
Adult Non-spawner (silver)	5	10

Dolly Varden charr are iteroparous, spawning several times during life. The Babbage River stock appears to have both virgin and resting (previously spawned) non-spawning stages, known locally as 'silvers'. A size limit of 425 mm was used in all data sets to differentiate virgin non-spawners from resting non-spawners. This size limit is based on the fork length above which spawning charr were consistently observed in the population. Thus, non-spawning charr larger than 425 mm were classified as resting, non-spawning adults (i.e., maturity code 5 or 10), and those below 425 classified as virgin, non-spawning juveniles and adults (i.e., maturity code 1 or 6).

Sagittal otoliths were removed from dead-sampled fish and placed in a scale envelope for later age determination. All age determinations were conducted at the Freshwater Institute. Otoliths were prepared by lightly grinding the lateral convex surface on a fine carborundum stone to expose the annual growth zones (annuli). Otoliths were partially cleared in a solution of benzyl-benzoate, placed in a depression slide, and aged under a dissection microscope according to the criteria outlined in Nordeng (1961). Length plotted against age, for each sex, is depicted on scatter diagrams and lines were fitted through these plots using the method of least squares (SAS Ver. 6.03) (SAS Inc. 1988).

The relative condition factor (K), a measure of the "robustness" of the fish, was determined by the formula:

$$K = \frac{W \times 10^5}{L^3}$$

where W = weight in grams,
and L = fork length in mm.

RESULTS

PHYSICAL RESULTS

Average daily water temperatures recorded in 1991 and 1992 are summarized in Fig. 7. Minimum and maximum air temperatures recorded in 1991 and 1992 are summarized in Fig. 8 and 9. The average daily staff gauge recordings for 1991 and 1992 are presented in Fig. 10.

BIOLOGICAL RESULTS

Population Parameters

Table 1 summarizes the dates on which the weir was in operation, the total number of charr enumerated, and the number of fish live- and dead-sampled in each of the three years. Also included in this table for each year are the number of charr tagged, the number of charr aged, and the number of charr recaptured (according to year of tagging). The daily catch of charr throughout the operation of the weir in 1990, 1991 and 1992 is presented in Fig. 11, and the length-frequency distributions (by 10 mm size intervals) for all charr sampled are shown in Fig. 12. Table 2 shows the change in mean length of the run over its duration, for each year of the study, according to five-day intervals. Biological data by age group and length interval for each of the three years is presented in Tables 3 to 8. Figure 13 shows the age composition of each 50 mm size class, calculated using the 1990 to 1992 combined data set. Figure 14 is a scatter plot of fork length versus age for each sex using the 1990 to 1992 combined data set. Frequency of females and males and the frequency of maturation of the sexes observed in 1990, 1991, and 1992 is shown in Table 9.

Recapture Data - Growth and Stock Size Estimate

Floy-tag recapture data is presented in Table 10 along with the calculated annual growth rate. Figure 15 shows the annual mean growth and standard deviations (mm) for male and female charr, grouped by 25 mm size classes. Means were determined from tagged individuals that were sexed externally sexed at the time of first capture and recaptured within a year.

Estimates of 15 141 ± 3 196 fish and 27.8% annual mortality, were derived for the 1991 anadromous stock size and 1991 instantaneous mortality rate, respectfully, using the Bailey's deterministic model (Appendix I and II). These values were adjusted to control for a tag loss rate of 11.3% (Armstrong 1965), yielding adjusted estimates of 13 639 ± 3 024 and 27.6%. A tabulation of all the raw data (grouped by year) is provided in Tables 11, 12 and 13.

Charr Behaviour Near Weir

Approximately 40% of the charr angled and Floy-tagged downstream of the weir in 1991 and 60% in 1992 were never recaptured by the weir in that particular season. Data on the length of time charr remained downstream of the weir in 1991 are in Table 14. For those that did move up through the weir, the average number of days charr spent downstream of the weir after being tagged was 3.2 ± 4.5 days (minimum = 0; maximum= 22 days). For those charr that were captured in the weir trap, tagged and released downstream, 67% and 84% were never recaptured in 1991 and 1992, respectfully.

None of the radio-tagged charr moved to neighbouring systems during the summer and fall of 1992. Four radio-tagged charr that were recaptured by the weir and released downstream (one eight times) remained within the Babbage River Drainage Basin and did not move to neighbouring systems. A tracking flight 5 days after tagging found that the majority of radio-tagged charr were between one and five kilometers downstream of the weir. Of the 14 charr that were radio-tagged, one got tangled in the weir and died, one was never located, and the remaining 12 charr moved approximately 50 kms upstream, after the weir was removed, to a single overwintering site on Canoe Creek by the next tracking flight on October 1, 1993.

CONCLUSIONS

RECOMMENDATIONS FOR FUTURE WEIR ENUMERATIONS

Based on the declining total counts between 1990 and 1992, the low recapture success of charr tagged and released downstream of the weir, and the radio telemetry results, it is likely that the weir deterred a portion of the run, particularly in years two and three of the project. We speculate that, in 1991 and 1992, charr had difficultly locating the trap due to the profile of the weir and the construction and location of the trap.

In 1991 and 1992, the 90° configuration of the weir did not funnel charr to the opening of the trap, making it difficult for them to find. In 1990, the partial fixed weir likely helped to direct fish into the trap which could possibly explain why catches were higher that year. We suggest for a full floating weir, funnelling of charr to the trap could be accomplished by running the channel iron at a 45° angle to the shore. A corresponding 45° adjustment to the wooden baseplate of each PVC panel would also be necessary. In this configuration the weir would still operate normally by submerging during high water and thus be prevented from washing out.

Another factor which likely contributed to the behaviour of charr around the weir in 1991 and 1992 was the trap being located in an area of lower current velocity. Placing the trap there may not have permitted the necessary increase in water velocity (in relation to velocities around the weir) in the mouth of the trap needed to stimulate charr to move upstream into it. This was exacerbated by the design of the trap (i.e., space between the conduit was too small, <1.27cm) reducing the flow of water into, and thus, out of the trap. The wire mesh trap used in 1990 did not restrict water flow to the extent that the trap used in 1991 and 1992 did. In addition, the trap in 1990 was located more centrally in the river where water velocities were higher, further increasing water flow through the trap. These two factors may also have contributed to the higher catches in 1990 compared to the other years. Without sufficient water flow through the trap, not only would the movement of charr into the trap be affected but also charr caught in the trap would be more likely to find their way back out between trap checks. Thus, we recommend that the PVC panels be positioned so that the trap (located at the upstream end of the angled row of panels) is in or adjacent to the section of river which has the greatest water velocity. The actual design of the trap must minimize the restriction of water flow through it, while still ensuring that the smallest anadromous juvenile fish will be caught. Aluminum conduit (1.27 cm dia.) spaced at the maximum allowable distance would be more suitable than plastic or steel mesh for

construction of the trap sides. Mesh sides, apart from damaging the kypes of spawning male charr, become badly clogged with leaf debris in the fall which is difficult to remove.

ACKNOWLEDGMENTS

The authors would first like to thank Lois Harwood for her considerable contributions to the 1992 project and Vic Gillman for bringing the original proposal to fruition. We are indebted to the Fisheries Joint Management Committee for providing the funding to conduct the weir enumerations and Polar Continental Shelf Project for providing logistical support. We would like to thank Larry Bartlett and Larry Larson from the Alaska Department of Fish and Game for their help on the design of the weir. We would also like to thank Al Kristofferson, George Low and Lois Harwood for reviewing an earlier manuscript, and Gary Carder for ageing the charr. Finally, we would like to acknowledge the following individuals for their expert help in the field (in alphabetical order): the late Narcisse Capot-blanc, Earl Esau, Rob Eno, Brian Ferguson, Pat Kasook, Mervin Joe, Troy McKerral (Aklak Air), John Max Kudlak, Wilson Malegana, Brad Parker, Charlie Ruben, Donna Rystephanuk, James Selamio, Ricky Selamio, and Mike Tyshinski. Our apologies to anyone inadvertently excluded.

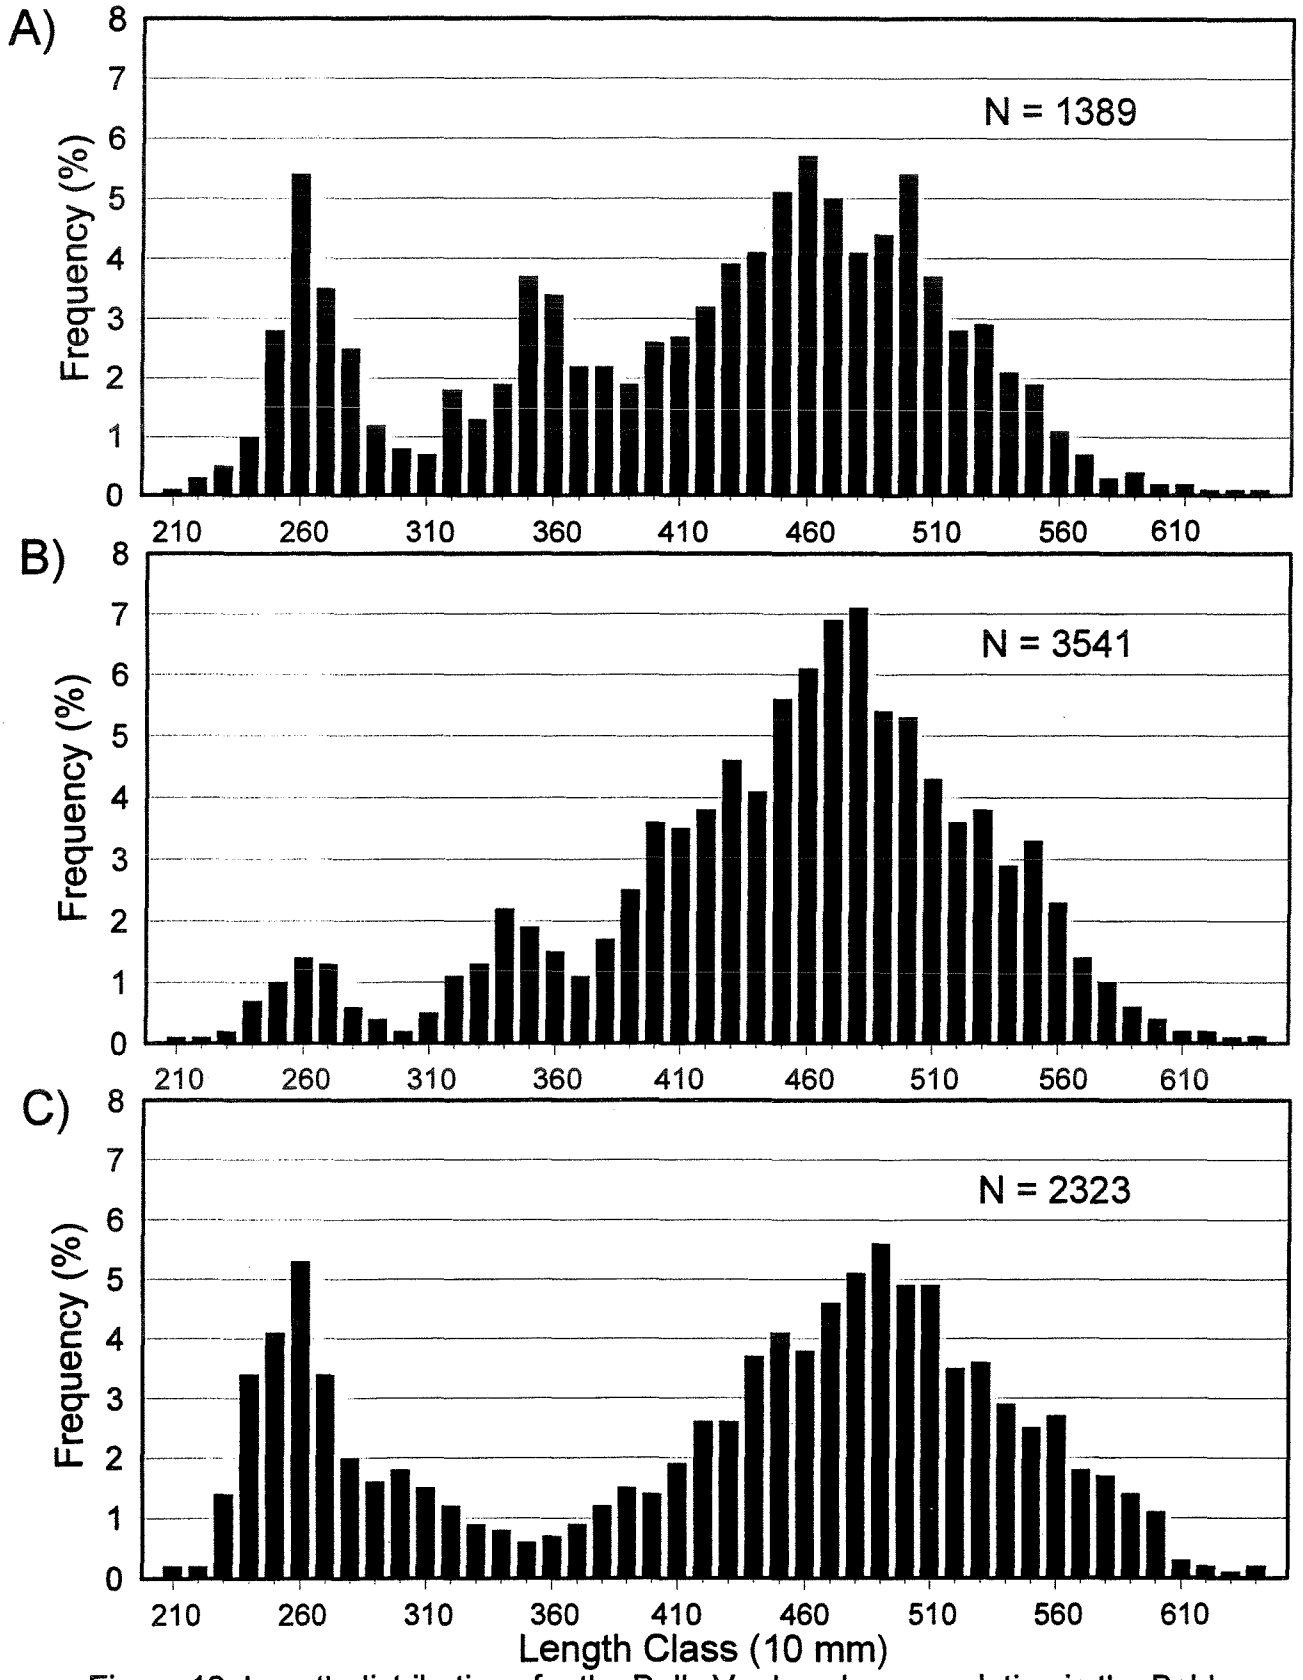

Figure 12. Length distributions for the Dolly Varden charr population in the Babbage River recorded from live- and dead-sampled charr caught by the weir during the upstream migration of the stock in 1990 (A), 1991 (B) and 1992 (C).

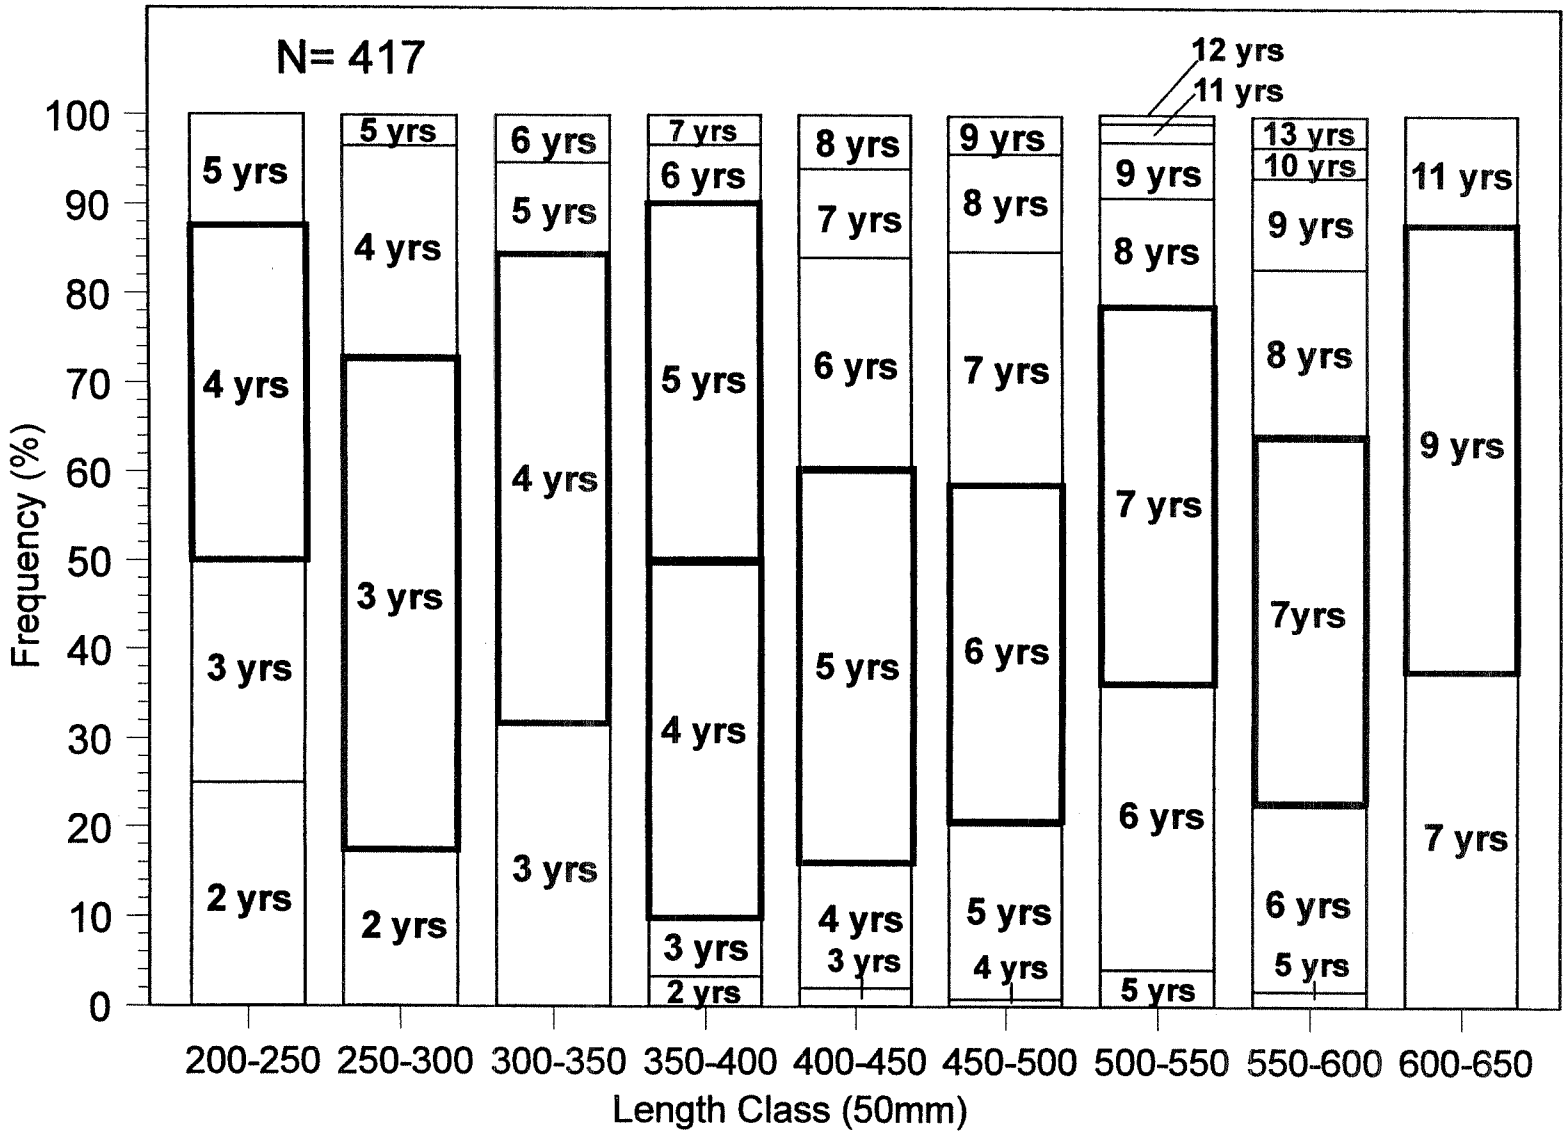

Figure 13. The age break-down of each 50 mm size class determine from the dead-sampled charr combined in 1990, 1991 and 1992 during the weir enumerations in the Babbage River. Ages outlined in heavy blocks are the most numerous age group.

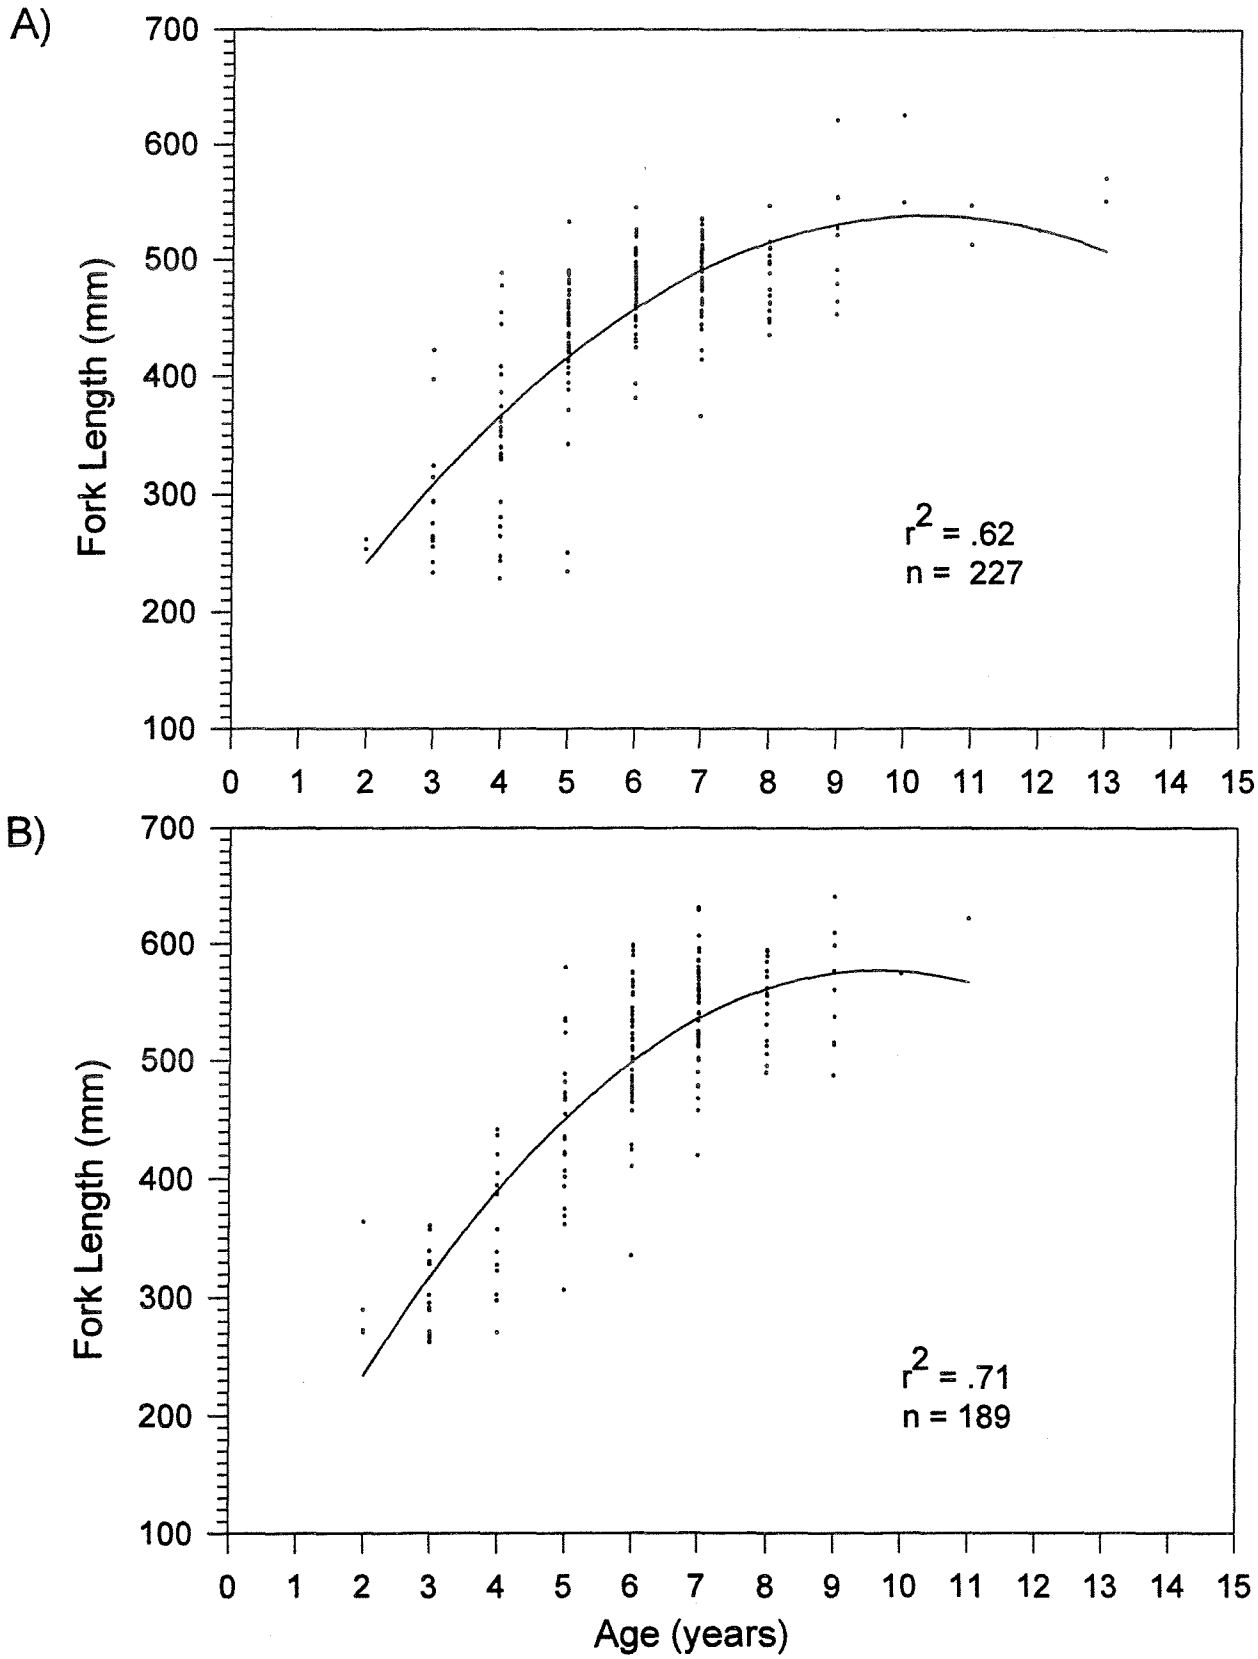

Figure 14. Scatter plot of age versus fork length for (A) female and (B) male Dolly Varden charr from charr from the Babbage River (1990 to 1992 data combined)

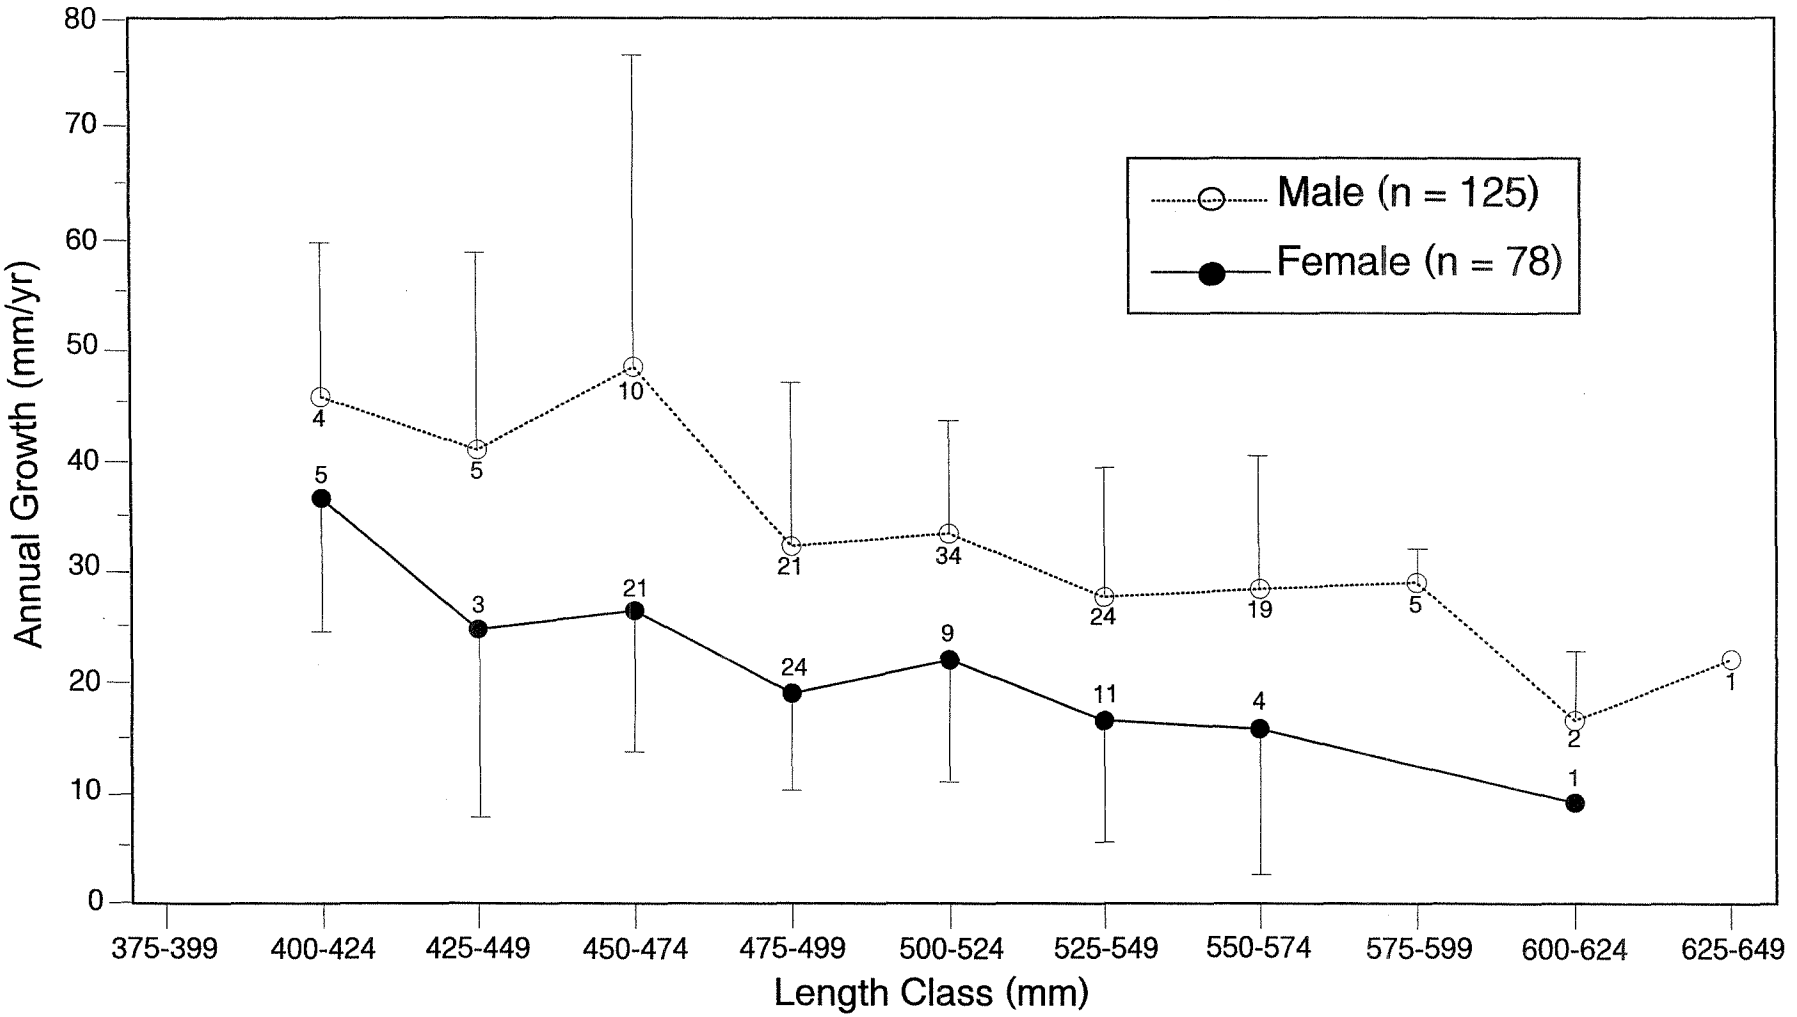

Figure 15. Annual mean growth in fork length, as determined from Floy-tag recaptured individuals, of male and female Babbage River charr, grouped by 25 mm size classes, The length classes presented are the fork length of the fish at the time the tag is applied. Thus, mean growth is the average growth in length that a male or female charr of that size class is predicted to make in one year. Only charr externally sexed at the time of recapture and only charr recaptured within one year were used in the analysis. Recapture data from all three years of the study are combined in this figure. In order to simplify the figure only positive standard deviation bars are presented with the male data and only negative standard deviation bars with the female data.

Average	54%	53%	46%	42%	49%

Table 10. Information regarding Floy-tagged and recaptured Dolly Varden charr in the Babbage River, Yukon north slope. Note that some individuals have been recaptured several times. These are listed as sequential rows in the table (e.g., Row 16 and 17) which are duplicated for the original tagging information. The recapture data and the calculated growth rate differs depending upon the recapture date. For sex: F= female, M= male, FSp= female spawner, MSp= male spawner, FSI= female non-spawner, MSI= male non-spawner, (.)= unknown sex and /or maturity.

Table 11. Biological data collected from both live- and dead-sampled Dolly Varden charr caught in the weir on the Babbage River in 1990. Note that (.) indicates missing data and 'clipped' means that the charr had the adipose fin removed.

	Location	Method	Day	Month	Year	Tag No. or Sample No.	Tag Color	Fork Lth	Round Weight	Sex	Maturity	Age	Notes

53	14	8	1991	.	.	.	.	.	.	not recaptured

Appendix I

Bailey's Estimator of Stock Size of Anadromous Charr Using Triple Mark Recapture Data

Babbage River Floy-Tag Recapture Data

Year	Fish Newly Marked	Fish Examined	No. of 1990 Tag Recaps.	No. of 1991 Tag Recaps
1990	433 (M_1)	-	-	-
1991	669 (M_2)	5170 (C_2)	78 (R_{12})	-
1992	-	4114 (C_3)	42 (R_{13})	123(R_{23})

Using Bailey's 'large sample' formula (Bailey 1951):

N_2= Estimate of Population Size in Interval 2 (i.e., 1991)

$$N_2 = \frac{(M_2)(C_2)(R_{13})}{(R_{12})(R_{23})} = \frac{(669)(5170)(42)}{(78)(123)} = 15\ 141$$

$$Var(N_2) = (N_2)^2\left(\frac{1}{R_{12}} + \frac{1}{R_{23}} + \frac{1}{R_{13}} - \frac{1}{C_2}\right)$$

$$= (15141)^2\left(\frac{1}{78} + \frac{1}{123} + \frac{1}{42} - \frac{1}{5170}\right) = 1021691$$

$$\text{Standard Deviation} = \sqrt{\text{Var.}} = \sqrt{1021691} = 3\ 196$$

Estimate of 1991 Stock Size = 15 141 ± 3 196 (68 % confidence limit)

If we assume a similar tag loss frequency of 11.3% as recorded for Dolly Varden charr (>150 mm) in southwestern Alaska (Armstrong 1965), then the new estimate becomes (R_{12}= 87, R_{13} = 47, and R_{23}= 137):

New Estimate of 1991 Stock Size = 13 639 ± 3 024 (68 % confidence limit)

Appendix II

Bailey's Estimator of Instaneous Rate of Mortality (Z) of Andromous Charr Using Triple Mark Recapture Data

Babbage River Floy-Tag Recapture Data

Year	Fish Newly Marked	Fish Examined	No. of 1990 Tag Recaps.	No. of 1991 Tag Recaps
1990	433 (M_1)	-	-	-
1991	669 (M_2)	5170 (C_2)	78 (R_{12})	-
1992	-	4114 (C_3)	42 (R_{13})	123(R_{23})

Using Bailey's 'large sample' formula (Bailey 1951):

S_{12} = survival rates between time 1 (i.e., 1990) and time 2 (i.e., 1991)

$$S_{12} = \frac{M_2\ R_{13}}{M_1\ R_{23}} = \frac{669\ \ 42}{433\ \ 123} = \frac{28098}{53259} = 0.5276$$

$$\text{Var}\ (S_{12}) = S_{12}^2 - \frac{M_2^2\ R_{13}(R_{13} - 1)}{M_1^2(R_{23})(R_{23} + 2)} = 0.5276^2 - \frac{669^2 . 42\ (42 - 1)}{433^2(123)(123 + 2)} = 0.011$$

$$\text{Standard Deviation} = \sqrt{\text{Var.}} = \sqrt{0.011} = 0.1049$$

$S_{12} = 0.5276 \pm 0.1049$ (68 % confidence limit)

Z_{12} = instantaneous rate of mortality between time 1 (i.e., 1990) and time 2 (i.e., 1991)

$Z_{12} = -\log_e S_{12} = -\log_e 0.5276 = 0.2777$

If we assume a similar tag loss frequency of 11.3% as recorded for Dolly Varden charr (>150 mm) in southwestern Alaska (Armstrong, 1965), then the new estimate becomes ($R_{12} = 87$, $R_{13} = 47$, and $R_{23} = 137$):

New Estimate of $S_{12} = 0.5300 \pm 0.1323$ (68 % confidence limit)

New Estimate of $Z_{12} = 0.2757$
