ABSTRACT

Wyeth, M.R., A.R. Kronlund, and M. Elfert. 2004. Summary of the 2002 British Columbia Sablefish (*Anoplopoma fimbria*) research and assessment survey. Can. Data Rep. Fish. Aquat. Sci. 1140: 50 p.

This document provides a summary of the methodology and results of the 2002 British Columbia sablefish research and assessment survey. The 2002 survey continued the time series of annual fall surveys initiated in 1988 and standardized beginning in 1990. Longline trap fishing was conducted at selected offshore and mainland inlet localities. Survey tasks were divided between two chartered commercial fishing vessels.

The indexing charter vessel conducted standardized indexing sets at nine offshore and five mainland inlet localities. These sets provide a catch rate based abundance index used for stock assessment. In addition, sablefish were tagged and released from the sets fished in the mainland inlet localities.

The tagging charter vessel conducted tagging sets at 15 offshore localities. Three types of tagging set were completed: Type 1 (traditional) tagging sets followed protocols used for tagging sets since 1995; Type 2 (systematic) tagging sets were conducted in the same localities and depth ranges as the offshore indexing sets; and Type 3 (random design) tagging sets were conducted at randomly selected locations within two of the offshore localities.

The distribution of catch rates in 2002 for the offshore indexing sets increased from that observed in 2001 to a level consistent with catch rates observed during the late 1990s. Catch rates for tagging sets and mainland inlet indexing sets were comparable to earlier surveys. Of the 31,452 sablefish captured, 19,847 were tagged and released, 566 previously tagged sablefish were recovered, and 7,378 were sampled for biological data.

RÉSUMÉ

Wyeth, M.R., A.R. Kronlund, and M. Elfert. 2004. Summary of the 2002 British Columbia Sablefish (*Anoplopoma fimbria*) research and assessment survey. Can. Data Rep. Fish. Aquat. Sci. 1140: 50 p.

Ce document fait la synthèse des méthodes et des résultats du relevé de recherche et d'évaluation de la morue charbonnière de la Colombie-Britannique effectué en 2002. Ce relevé s'ajoute à la série chronologique des relevés d'automne annuels qui ont commencé en 1988 et ont été normalisés à partir de 1990. Le relevé a été effectué par deux bateaux de pêche commerciale affrétés et a consisté à pêcher la morue au moyen de casiers fixés à des lignes de fond dans des endroits choisis au large et dans des bras de mer continentaux.

Un des bateaux affrété a effectué la pêche indicatrice normalisée à neuf stations au large et à cinq stations dans des bras de mer continentaux pour obtenir un indice d'abondance fondé sur les taux de capture, à des fins d'évaluation du stock. En outre, des morues capturées dans les bras de mer continentaux ont été marquées et libérées.

L'autre bateau affrété a servi à capturer des morues pour le marquage à quinze stations au large. Trois types de mouillages de casiers ont été effectués à des fins de marquage du poisson : mouillages de type 1 (traditionnels) réalisés selon le protocole utilisé pour le marquage depuis 1995; mouillages de type 2 (systématiques) effectués aux mêmes stations et profondeurs que les mouillages de pêche indicatrice au large; mouillages de type 3 (aléatoires) effectués à des endroits choisis au hasard près de deux des stations au large.

Les taux de capture pour les mouillages de pêche indicatrice au large en 2002 étaient en hausse par rapport aux taux de 2001 et correspondaient aux taux observés à la fin des années 1990. Les taux de capture pour les mouillages de marquage et les mouillages de pêche indicatrice dans des bras de mer continentaux étaient comparables à ceux des relevés antérieurs. Des 31 452 morues charbonnières capturées, 19 847 ont été marquées et relâchées, 566 morues charbonnières marquées lors d'années antérieures ont été recapturées, et 7 378 ont été échantillonnées pour obtenir des données biologiques.

1.0 INTRODUCTION

Sablefish (*Anoplopoma fimbria*) are an abundant and commercially valuable species throughout their range in the North Pacific. They have a long history of exploitation in Canadian waters with landings reported as early as the early 1800s (McFarlane and Beamish 1983). British Columbia fishermen harvest sablefish with longline trap, longline hook, and trawl gear along the continental shelf at depths up to 1800 m. The British Columbia sablefish fishery landed approximately 4000 metric tons annually for the period 1997 to 2001. The majority of the fish (>75%) were captured using trap gear.

In 1988 an annual sablefish research and assessment survey of the British Columbia coast was initiated. For details of how the survey has expanded and changed over the years, see Wyeth and Kronlund (2003). Each year, fishing was conducted at selected localities using trap gear consistent with the commercial fishery. The fishing protocol was refined over the first few years and was standardized beginning in 1990. These standardized "indexing sets" were designed to track trends in abundance and biological characteristics at the selected localities. In addition to the indexing component of the annual survey, sablefish were tagged and released beginning in 1991. In 1994, "tagging sets" specifically for capturing sablefish for tag and release became part of the annual survey and in 1995 localities specifically for tagging sets were added.

The 2002 survey was a continuation of the 1990 to 2001 standardized time series and followed the same protocols for fishing gear, catch monitoring, biological sampling, and tagging. For details on surveys conducted from 1988 through 1993, see Smith et al. (1996); for surveys in 1994 and 1995 see Downes et al. (1997); for surveys from 1996 to 2000 see Wyeth and Kronlund (2003), for the 2001 survey see Wyeth et al. (2003). For details concerning tag releases from 1977 through 1981 see Beamish et al. (1978, 1979, 1980, and 1983) and for tag releases from 1982 through 1987 see Murie et al. (1995). In 2002, indexing and tagging sets were conducted at offshore and mainland inlet localities. In addition, systematic tagging sets as well as sets designed to examine the feasibility of fishing in randomly selected locations were conducted.

This document summarises the methods and results of the 2002 survey and consists of a main body of text with supporting appendices. Tables and figures referred to in the main text are sequentially numbered. Tables and figures in the appendices are labelled with the letter code of the appendix and a sequential number, e.g. Table A.2 for the second table in Appendix A.

2.0 METHODS

The 2002 sablefish survey followed protocols that have evolved over the 15 year life of the annual survey. Sets were made at selected offshore and mainland inlet localities along the British Columbia coast. Sets were of two types: 1) standardized "indexing" sets had prescribed gear requirements and were used to collect catch rate data intended to index trends in abundance and to obtain fish for biological sampling; 2) "tagging" sets were designed specifically to capture sablefish for tag and release. The protocol for indexing sets developed over the first few years of the time series and was standardized beginning in 1990. The protocol for tagging sets has been standardized since 1996.

There were a number of changes to the 2002 survey design compared to surveys in previous years as summarised below.

1. The 2002 survey tasks were split between two vessels. One vessel conducted the offshore and mainland inlet indexing components of the survey (indexing charter) while the second vessel conducted the offshore tagging component (tagging charter).
2. No fish were tagged from offshore indexing sets in 2002 which was unlike sets conducted in previous years when sablefish in excess of the biological sampling requirements were tagged and released.
3. Replicate indexing sets were conducted at three localities in 2002 which was unlike previous years when only one set was made in each depth strata and locality combination.
4. The offshore tagging program included not only the traditional (Type 1) tagging sets, but also new systematic (Type 2) tagging sets and sets designed to examine the feasibility of fishing in randomly selected locations (Type 3). The Type 1 tagging sets were conducted at the six offshore tagging localities. The Type 2 tagging sets were conducted at the offshore indexing localities and targeted at the indexing depth strata. For the Type 3 sets, locations were randomly selected within two of the indexing localities.

2.1 SURVEY VESSELS

The F/V Pacific Viking was chartered to conduct the indexing charter portion of the 2002 sablefish research and assessment survey. The vessel was skippered by Albert "Deacon" Melynchuk and a total of 125 sets were completed during the period from October 4 to November 5, 2002 (Table 1). Detailed information for each set conducted during the 2002 indexing charter is shown in Appendix A.

The F/V Viking Sunrise was chartered to conduct the tagging charter portion of the 2002 survey. The vessel was skippered by Jason Olsen and a total of 90 sets were completed during the period from October 5 to November 12, 2002. Detailed information for each set conducted during the 2002 tagging charter is shown in Appendix B.

2.2 SURVEY LOCALITIES

Unlike previous years, when the skippers were instructed to set gear in a loosely defined area, the geographic boundaries of the localities were defined in 2002 (Table 2, Figure 1).

2.2.1 Indexing Localities

Nine offshore indexing localities were visited in 2002 (Figure 2 and Figure 3). From north to south they were Langara Island-North Frederick, Hippa Island, Buck Point, Gowgaia Bay, Cape St. James, Triangle Island, Quatsino Sound, Esperanza Inlet, and Barkley Canyon.

2.2.2 Tagging Localities

Six offshore tagging localities were visited in 2002 (Figure 2 and Figure 3). From north to south they were Rennell Sound, Tasu Sound, Middle Ground, Pisces Canyon, Estevan Point, and Father Charles Canyon.

2.2.3 Mainland Inlet Localities

Five mainland inlet localities were visited in 2002. From north to south they were Portland Inlet, Gil Island, Finlayson Channel, and Dean/Burke Channel (Figure 4). In previous years the skippers were directed to make five sets in each inlet locality and no specific locations

were given. Nonetheless, there was a fair degree of consistency of the set locations within each inlet among years. In 2002, five locations were chosen within each inlet locality to spatially distribute the sets within each locality and to ensure that consistency with the positions of sets conducted in previous years could be maintained. The skipper was directed to make one set in each location.

2.3 DEPTH STRATA

Within the offshore localities, the skipper had discretion over the exact location of all sets provided the sets were made in the specified depth strata.

Sets made at the offshore indexing localities in 2002 were targeted at seven depth strata (Table 4): 274-457 m (150-249 fm), 457-641 m (250-349 fm), 641-824 m (350-449 fm), 824-1006 m (450-549 fm), 1006-1189 m (550-649 fm), 1189-1389 m (650-749 fm), and 1372-1827 m (750-999 fm). Beginning in 1990, five core depth strata (D1 - D5) have been fished each year at each of the indexing localities (Wyeth and Kronlund 2003). Beginning in 1999, the core depth strata were supplemented with additional deep sets. During the 1999 survey, one deep set was targeted at approximately 1097m (600 fm) at each of the Queen Charlotte Island indexing localities (Wyeth and Kronlund 2003). For the 2000 and 2001 surveys, deep sets were targeted at 3 depth strata at indexing localities off the west coast of Vancouver Island: 1188-1280 m (650-700fm), 1280-1463 m (700-800 fm), and deeper than 1463 m (800 fm). Additional deep sets were fished off the Queen Charlotte Islands at the indexing localities as well as at other locations. These sets were targeted at a single stratum bounded by 1188-1463 m (600-800 fm). The deep sets were redesigned for the 2002 survey. Two deep depth strata (D6-D7) were defined that followed the same 183 m (100 fm) ranges of the D1-D5 core depth strata (Table 4). Sets were made in all nine offshore indexing localities and the deep locations off the Queen Charlotte Islands added in 1999 were not fished.

The indexing charter vessel made one indexing set in each of the seven depth strata at each indexing locality. To examine variation of catch rates within each locality, replicates sets in each depth stratum were conducted at three localities: Hippa Island, Gowgaia Bay, and Esperanza Inlet. A total of 21 sets were completed in each of these localities (Table 3).

To provide a systematic distribution of tag releases over the depth range and area of the indexing survey, the tagging charter vessel made one Type 2 tagging set in each of the seven depth strata at each indexing locality. In addition, the feasibility of fishing at randomly selected locations was evaluated by fishing five sets at randomly selected coordinates within each of the Hippa Island and Barkley Canyon localities.

Type 1 (traditional) offshore tagging sets were targeted where the highest catch rates were expected at 457-824 m (250-450 fm, Table 4) to maximise the number of releases per set. Two to three tagging sets were made at each tagging locality.

Sets at the mainland inlet localities were made at the prevailing depth of the set location (Table 4). Fishing within specific depth strata was not possible because of the steep-sided bathymetry of the inlets. Five sets were made at each mainland inlet locality, with one set positioned at each of the locations identified in Figure 4.

2.4 FISHING GEAR AND OPERATIONS

The fishing gear and operations used in 2002 were consistent with the protocol of surveys from 1990 onwards (Wyeth and Kronlund 2003). All sets were made using the charter vessels' longline trap gear which is typical of that employed in the commercial sablefish trap fishery. For a more detailed description of the survey fishing gear and the setting and hauling procedures, see Wyeth and Kronlund (2003). Briefly, each set or "string" of longline trap gear consisted of a line resting on the ocean floor (groundline) with baited traps attached at intervals along its length (Figure 5). The groundline was secured to the ocean floor by anchors at each end and the location of the string was marked by floats attached to the groundline by anchorlines.

The start and end positions of each set were recorded from the vessels' global positioning system (GPS) when the first and last anchors were set over the stern. The start and end bottom depths were recorded from the vessels' depth sounder when the respective anchors were set. The mean bottom depth was calculated as the average of depth recordings from the vessels' depth sounder at one-minute intervals between the first and last anchors being set. The duration, or soak time, of the set was calculated as the time elapsed between the first anchor being set over the stern and the first anchor hauled aboard. Figure C.1 shows an example of a completed bridge log data form. In addition to the bridge log, science staff also observed each set from the deck and completed a set log (Figure C.2).

All sets were made using traps with black mesh. All traps had two stainless steel escape rings (Figure 5). Some of the traps were new to the indexing charter vessel and had not been used for commercial fishing yet. These traps had mesh over the escape ring openings rather than being sewn shut with net twine as with the previously fished traps. The escape rings on the tagging charter vessel traps were sewn shut with net twine. The vessel skippers reported that the escape rings on the indexing charter vessel had internal diameters of 86 mm ($3\frac{7}{8}$ inch) while the tagging charter vessel had 95 mm ($3\frac{3}{4}$ inch).

Indexing sets were made using strings of 25 traps and each trap was baited with an approximately 1 kg block of frozen squid (*Loligo opalescens*) in a bait bag. All tagging sets were baited with a combination of a 1 kg block of frozen squid in a bait bag and approximately 3 kg of frozen Pacific hake (*Merluccius productus*) loose in the trap. Type 1 tagging sets consisted of strings of approximately 65 traps while Type 2 and Type 3 tagging sets had 25 traps.

2.5 CATCH AND EFFORT DATA COLLECTION

2.5.1 Indexing Sets

The catch of all species in each trap was counted and weighed. All weights were taken using a Marel M1100 portable, motion-compensating electronic platform scale. Small catches of animals weighing less than 1 kg were counted but not always weighed while large catches of such animals were weighed but not always counted. Effort data was calculated by tallying each trap as it was hauled aboard. Any damage to the trap was noted and necessary repairs were affected before the trap was set again. Figure C.3 shows an example of a completed catch log form for an indexing set.

2.5.2 Tagging Sets

The collection of catch composition and effort data for tagging sets followed the protocol used for the indexing sets, except that no weights were recorded due to the lack of a motion compensating scale.

2.6 CATCH PROCESSING

2.6.1 Recovered Tagged Sablefish

Previously tagged sablefish recovered during survey sets were set aside as the catch was sorted. These fish were sacrificed and sampled after the set was completely hauled aboard. The fish were measured for fork length (L) in millimetres (mm). The abdominal cavities were opened and the gonads were examined to determine the fish sex (S) and to visually estimate the state of maturity (M, see Appendix D). Sagittal otoliths (O) were collected for subsequent age determination. The otoliths were excised from the fish, cleaned, and stored in 50% glycerine and 3% thymol solution in Tres Bien plastic trays. Due to time limitations for some sets, the tag identification numbers on the recovered tagged fish were recorded and the fish were frozen whole to be sampled on shore at a later date. The round body weights (W, dekagrams) of these fish were also recorded. Figure C.4 shows an example of a completed sablefish tag recovery sampling form.

2.6.2 Biological Samples

Sablefish were measured for fork length in millimetres (mm) and the whole body weight was recorded in grams (g) or kilograms (kg). The abdominal cavities of the fish were opened to determine the sex and a visual estimate of the state of maturity (Appendix D). Sagittal otoliths were excised from the fish, cleaned, and stored in 50% glycerine and 3% thymol solution in Tres Bien plastic trays.

2.6.2.1 Offshore Indexing Sets. All the sablefish captured during the offshore indexing sets were used for biological samples. All the fish from selected traps from each set were examined for LSMO, and W if weather conditions permitted accurate measurements. The goal was to obtain a sample of at least 50 fish per set. The specific selection method depended on the sablefish catch rate and varied from every trap, to every second or third trap, to an ad hoc selection of traps spaced throughout the string. The balance of the sablefish were examined for LS. Figure C.5 shows an example of a completed LS(W)MO sampling form while Figure C.6 shows an example of a completed LS sampling form.

2.6.2.2 Inlet Indexing Sets. Fish from selected traps throughout the inlet indexing sets were examined for LS(W)MO. The goal was to obtain a sample of at least 50 fish per set. The specific selection method depended on the sablefish catch rate and varied from every trap, to every second or third trap, to an ad hoc selection of traps spaced throughout the string. The remainder of the fish were tagged and released (see below).

2.6.2.3 Tagging Sets. Only sablefish in excess of the tagging goals (see below) from the Type 1 tagging sets were collected for biological samples. These fish were collected for an investigation of the effects of freezing and thawing on length measurements. A potential length change due to freezing is of particular concern as tagged sablefish recovered during the course of commercial fishing are typically frozen whole at sea and then thawed and sampled on shore. Sablefish were selected for sampling based on size with the goal of obtaining equal numbers of

fish in each of 19 fork length groups. Specifically, 10 fish were required in each 25 mm interval from 450 to 950 mm. Each fish was measured (fork length) live and tagged following normal tagging protocols (see section 2.6.3.2). Fish were then sacrificed and measured again. Finally, fish were frozen in the round and returned to shore where they were weighed, measured for length a third time, and the sex determined. All length measurements were made without knowledge of the previous measurements. The results of this investigation will be reported elsewhere.

2.6.3 Tagging

2.6.3.1 Tag Type.

All sablefish were tagged using a Floy FD-94 T-bar anchor tag which has similar characteristics to the FD-68B model used during surveys until 2000. The newer model has an improved coating to prevent wear of the tag label. The information printed on the tag appeared as:

CSA REWARD PACIFIC BIO. STATION
NANAIMO, B.C. CANADA *## ## ###

where "*" is a letter and "#" is any integer from 0 to 9, e.g. A00 123 456.

2.6.3.2 Tagging Procedures

2.6.3.2.1 Indexing Sets. No sablefish captured during offshore indexing sets were tagged. During the inlet indexing sets, fish in excess of the biological sampling requirements were tagged. Fish to be tagged were transferred from the sorting area using plastic baskets to a 2400 litre fibreglass holding tank secured to the vessel's deck. The tank received a continuous supply of fresh seawater from the vessel's fire pump system. Fish were removed from the holding tank by hand or with a dip-net and then measured for fork length (mm) on a wooden measuring board. The tag was inserted on the left side of the fish at the base of the dorsal fin using a Mark II Long Tagging gun. The tag was injected approximately 1 cm below, and 2-3 cm behind the anterior insertion of the first dorsal fin. The tag was angled into the fish so the tag could stream and the vertebral column and internal organs would not be damaged. Any significant injuries to the fish were recorded prior to the fish being released. Figure C.7 shows an example of a completed tagging form.

2.6.3.2.2 Tagging Sets. Tagging procedures for tagging sets followed the same protocols used during indexing sets. The goal of the Type 1 tagging sets was to tag and release a total of 1000 sablefish in each of the 6 offshore tagging localities. Once this goal had been achieved, tagging was discontinued and the remainder of the catch was processed by the vessel to be landed as commercial catch. All the sablefish captured during the Type 2 and Type 3 tagging sets were tagged and released.

Table 5 summarizes the different set types conducted during the 2002 survey.

2.7 OCEANOGRAPHIC SAMPLING

A VEMCO MiniLog TD or TDR (temperature or temperature/depth) recorder was attached to a trap on selected sets conducted by the indexing charter vessel. These data will be summarised elsewhere.

3.0 RESULTS

3.1 CATCH RATES

The distribution of catch rates (number of sablefish/number of traps) achieved for each set is summarised by boxplots by year for each of the offshore indexing, offshore tagging, and inlet indexing set types (Figure 6). The lower bound of the box indicates the first quartile (25th percentile) of the data and the upper bound of the box indicates the third quartile (75th percentile). The horizontal line that divides the box is the median (50th percentile). The upper and lower whiskers are positioned at 1.5 times the inter-quartile range. Open circles indicate data values that fall outside the whiskers, or outliers. The lightly shaded rectangle positioned in each box represents an approximate 95 percent confidence interval for the sample median. Solid circles indicate the mean catch rate for each group. The nominal data are presented here with no attempt to filter data or standardize for any factors. All traps that could have captured fish were included in the calculation of catch rates. For example, holed or fouled traps were included while open traps were excluded. The fishing protocol has varied over the time period shown (Wyeth and Kronlund 2003). Specifically, the more recent surveys have spanned a greater depth range than the early surveys. In addition, baiting practices have not been consistent. Deep indexing sets in 1999 were baited with both Pacific hake and squid and the amount of Pacific hake used in tagging sets varied from year to year. Indeed, the 1988 and 1989 surveys were significantly different than subsequent surveys, with much longer strings and different baiting practices (Wyeth and Kronlund 2003).

High catch rates were achieved during indexing sets until 1993, but from 1994 to 2000, catch rates were consistently at a lower level (Figure 6). The 2001 survey had the lowest mean indexing catch rate and also exhibited significantly reduced variability of catch rates. Indexing set catch rates in 2002 were at levels similar to those achieved in the late 1990s.

In years when both offshore indexing and tagging sets were conducted, the catch rates for tagging sets were greater (Figure 6). This is may be due to the depths targeted by the traditional tagging sets but is more likely due to the addition of Pacific hake to the bait load. The effect of bait is demonstrated by comparing the catch rates of Type 2 tagging sets and the indexing sets completed in 2002. The distribution of catch rates achieved for each set is summarised using boxplots by locality for the offshore indexing and Type 2 tagging sets (Figure 7). These two set types were conducted in the same localities and at the same depths. The major difference between the sets types was that the tagging sets were baited with both Pacific hake and squid while the indexing sets were baited with squid only.

Catch rates at inlet localities have remained relatively consistent among years with the exception of high catch rates in 1998 and 1999 (Figure 6).

3.2 CATCH COMPOSITION

Thirty-one species or taxonomic groups were captured during the 2002 indexing charter (Table 6). Other than sablefish, the most common species in order of total weight captured were arrowtooth flounder (*Atheresthes stomias*), pectoral rattail (*Albatrosia pectoralis*), roughscale rattail (*Coryphaenoides acrolepis*), rougheye rockfish (*Sebastes aleutianus*), Pacific halibut (*Hippoglossus stenolepis*), lingcod (*Ophiodon elongatus*), and Pacific sleeper sharks (*Somniosus*

pacificus). Only 3 Pacific sleeper sharks were captured but the large size of this species resulted in a significant weight. Other species accounted for minor fractions of the total catch.

Thirty-four species or taxonomic groups were captured during the tagging charter. Catch weights were not recorded but the relative abundances of species other than sablefish were generally consistent with the catch of the indexing charter. An exception to this was that the tagging charter captured relatively fewer rattails (family Macrouridae) and more tanner crabs (*Chionoecetes* sp.). These differences may be explained by the relatively deeper depths fished by the indexing charter. The differences could also be attributed to the Pacific hake and squid bait used by the tagging charter compared to the indexing charter which used squid only.

3.3 SABLEFISH SAMPLING AND TAGGING

Of the 31,452 sablefish captured during the 2002 survey, 27,801 were either tagged or used for biological sampling (Table 8). A total of 19,847 sablefish were tagged and released with 10,405 from offshore indexing localities, 5,903 from offshore tagging localities, and 3,549 from the inlet localities. In addition, 7,378 sablefish were sampled for length and sex of which 5,692 were also examined for maturity state, otoliths were collected from 5,682 and 2,198 were weighed. A total of 566 previously tagged sablefish were recovered during the 2002 survey.

The sex ratio varied among localities from 23 % to 68 % males (Table 9). In general, proportionally fewer males were seen at the inlet localities than at the offshore localities. The mean fork length of females was greater than that of males at all localities.

Details on the number of sablefish captured, sampled, and tagged for each set are shown in Appendix E for the indexing charter and Appendix F for the tagging charter.

4.0 ACKNOWLEDGEMENTS

This document reflects the contributions of many individuals. The Canadian Sablefish Association provided coordination and support for the 2002 survey, as it has done for surveys since 1994. The staff of Archipelago Marine Research (AMR) assisted in the preparation of the scientific equipment and supplies as well as providing scientific staff for the survey. The scientific staff that conducted the indexing charter included Malcolm Wyeth (Fisheries and Oceans Canada), Daniella Imhof (AMR) and Rob Havers (AMR). Margo Elfert (AMR), John Manning (AMR), and Dean Gaidica (AMR) conducted the tagging charter. A special thanks is due to the skippers and crews of the survey vessels, without whom the survey would not have been completed. Albert "Deacon" Melynchuck, Tom Amirault, Kevin Woodman, Don Enockson, and Dave Holomego crewed the Pacific Viking. Jason Olsen, Kevin Pogue, Rick Schneider, Peter Snelling, Arvend "Butch" Acton, and Trevor Olsen crewed the Viking Sunrise.

¹The South Moresby Rockfish Protected Area (RPA) overlaps slightly with the Cape St. James survey locality so sets were not made in the Northwest corner of the locality. The South Moresby RPA is described as:, McLean-Fraser Point to Grey Rock: Sub-areas 2-31 to 2-37 and those portions of Sub-areas 102-3, 130-3 and 142-1 that are inside of a line that begins at 52 deg 12 min north and 131 deg 25 min west, then south westerly to 52 deg 11 min north and 131 deg 30 min west, then south-easterly to 51 deg 49 min north and 130 deg 57 min west, then northerly to 51 deg 54 min north and 130.deg 54 min west, then north-easterly to 51 deg 59 min north and 131 deg west.

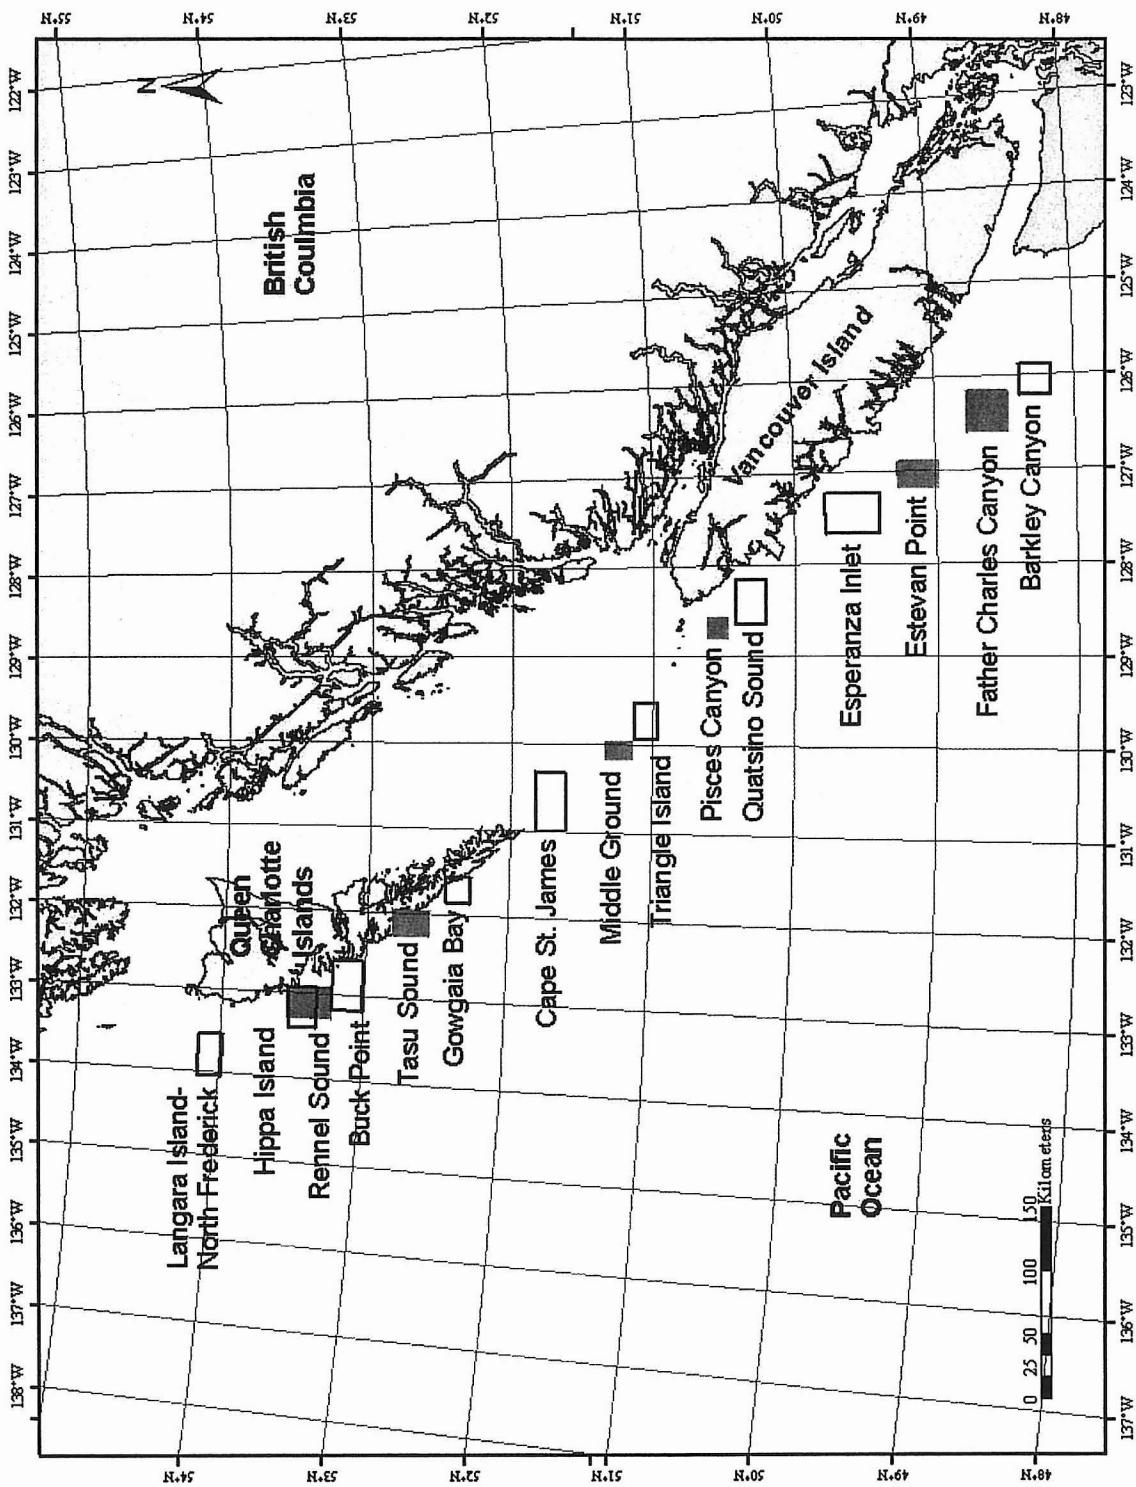

Figure 1. Geographic boundaries of offshore localities. Open boxes indicate an indexing locality while tagging localities are indicated by shaded boxes.

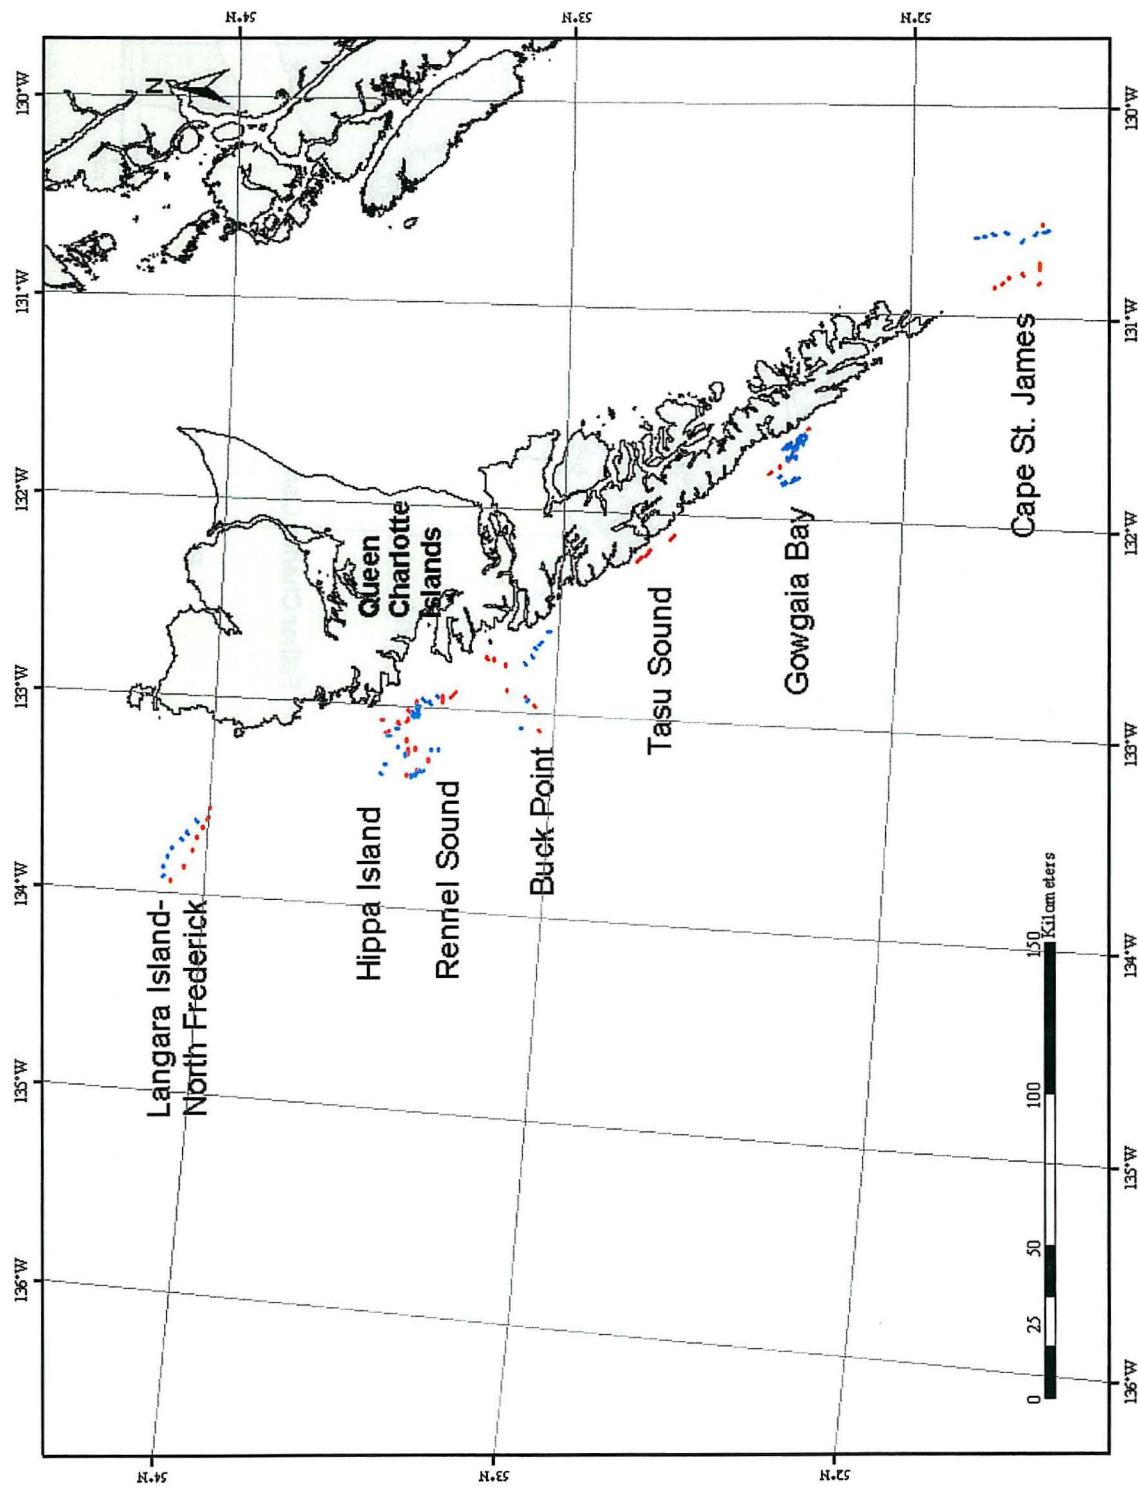

Figure 2. Locations of northern sets completed during the 2002 sablefish research and assessment survey. Sets conducted by the Pacific Viking (indexing charter) are shown in blue while sets conducted by the Viking Sunrise (tagging charter) are shown in red.

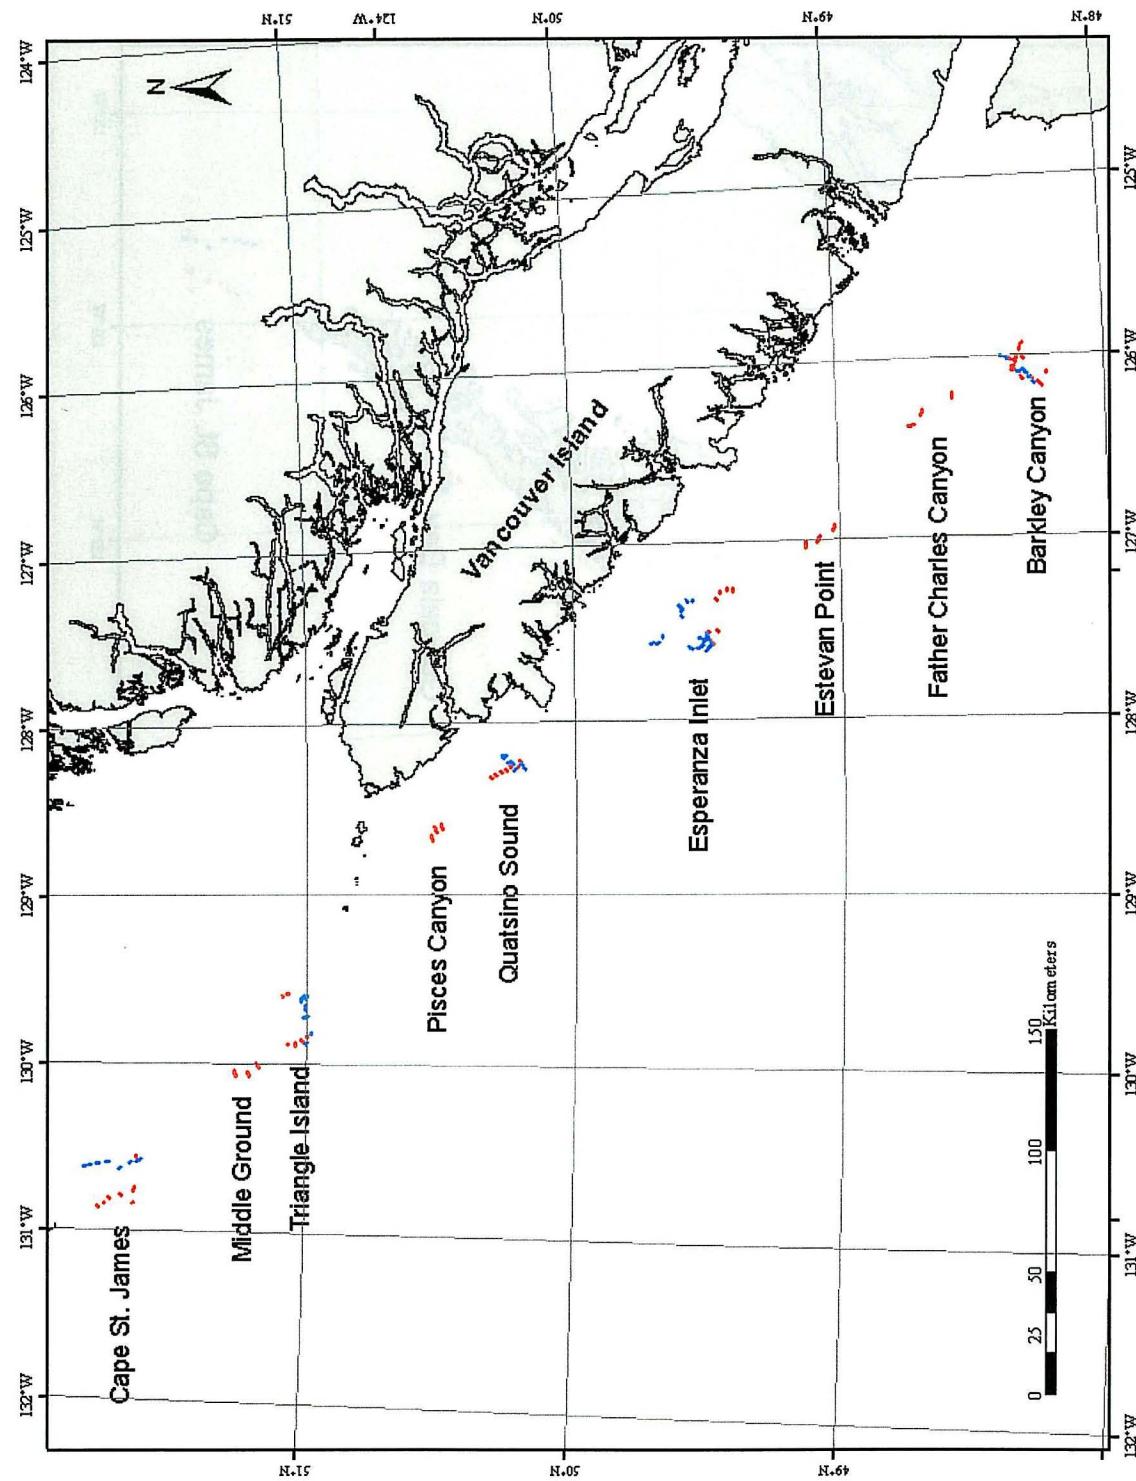

Figure 3. Locations of southern sets completed during the 2002 sablefish research and assessment survey. Sets conducted by the Pacific Viking (indexing charter) are shown in blue while sets conducted by the Viking Sunrise (tagging charter) are shown in red.

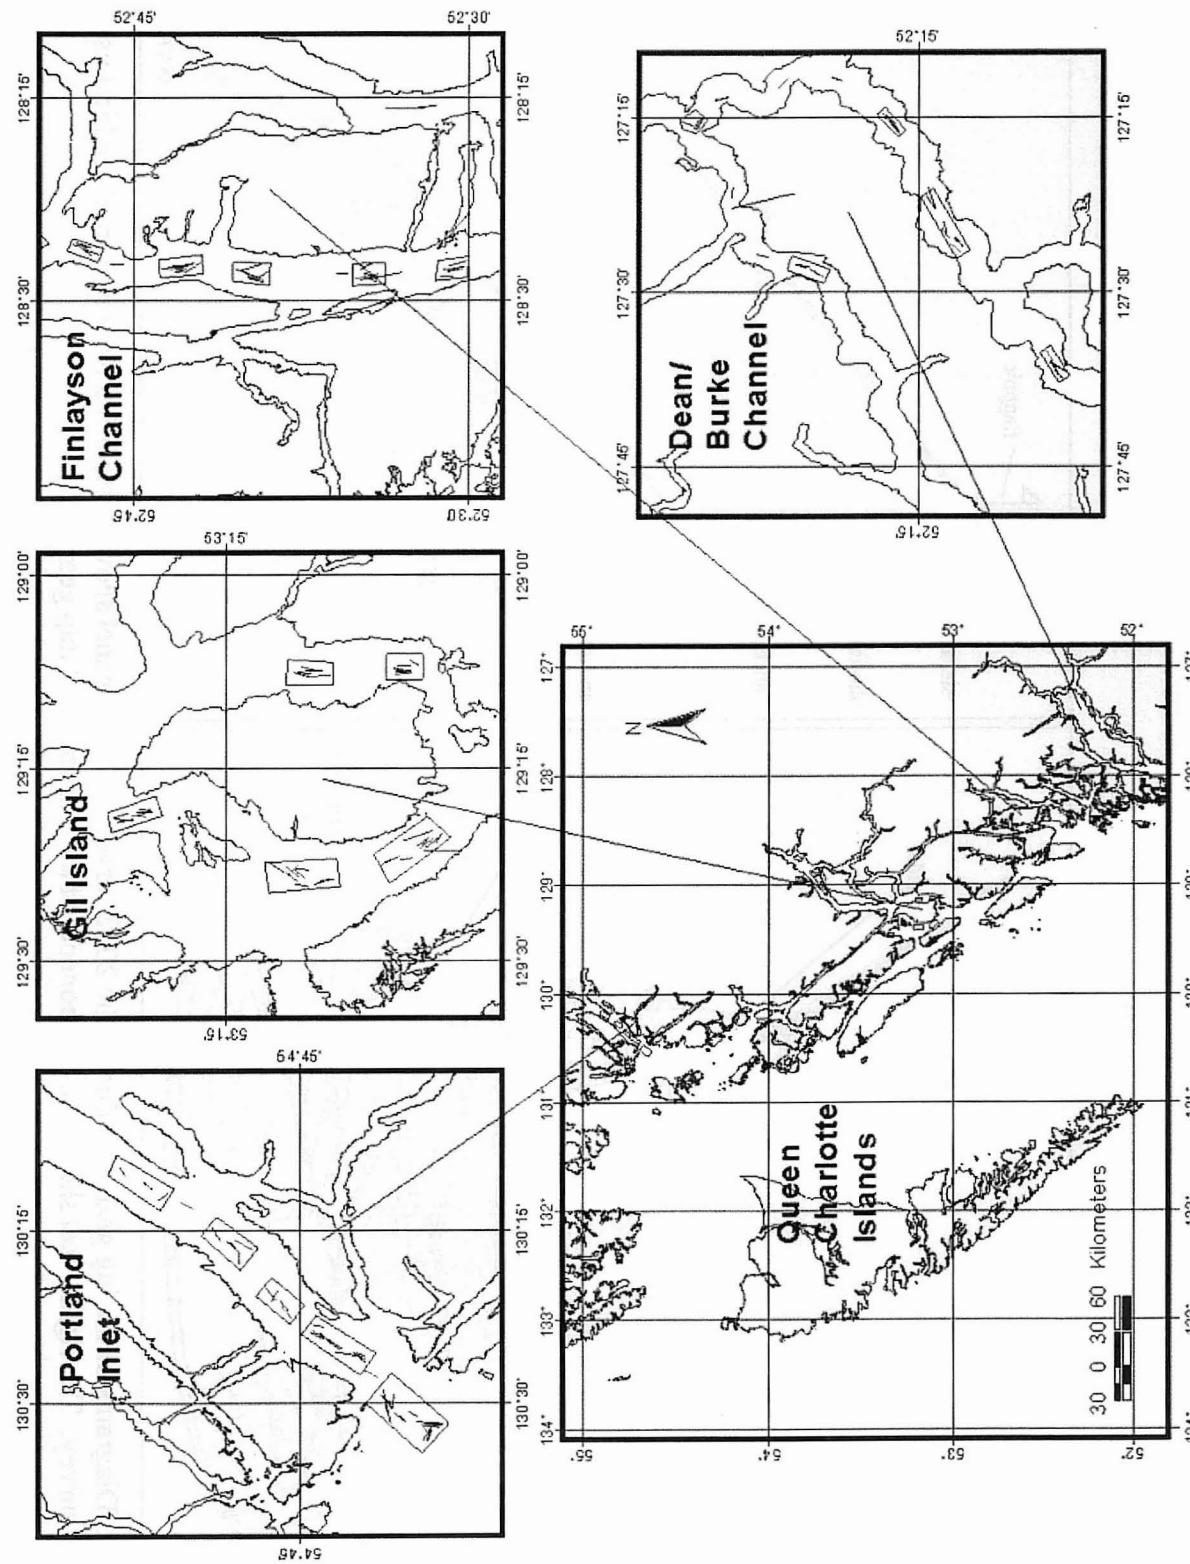

Figure 4. Sablefish research and assessment survey mainland inlet localities. Sets conducted from 1994 to 2001 are shown in black while the 2002 sets are shown in red. The black polygons indicate the locations where the skippers were directed to set.

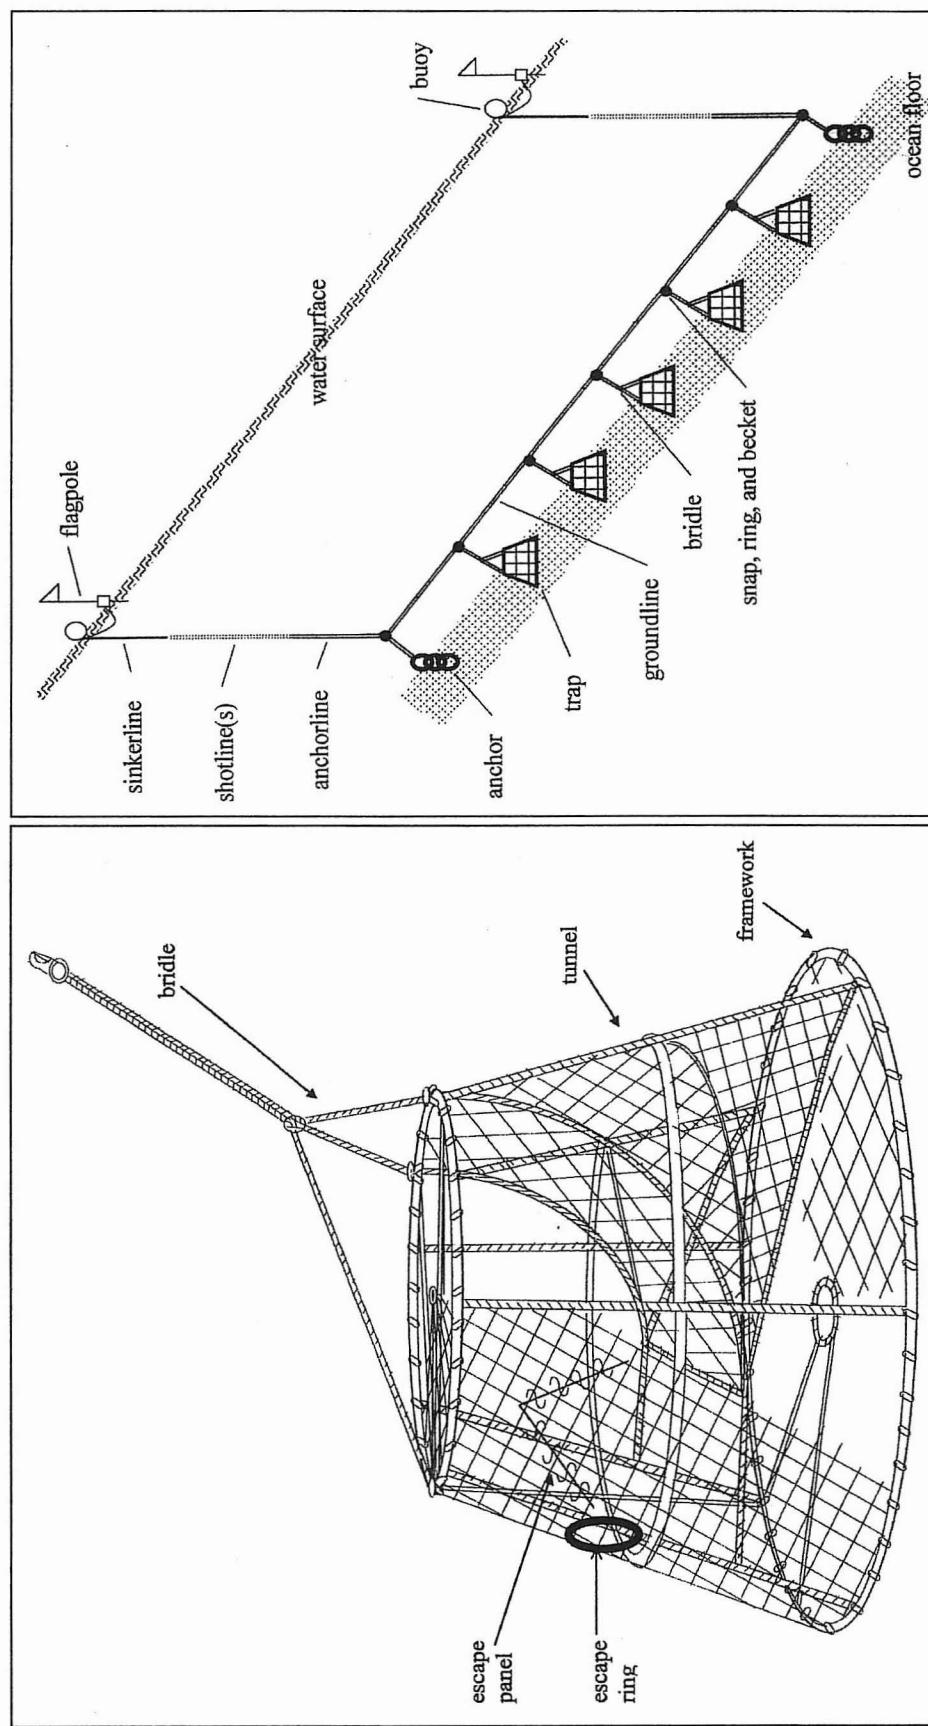

Figure 5. Diagrams of fishing gear used during the 2002 survey. The left panel shows a modified Korean trap of the kind used during the 2002 survey. The right panel shows the components of a set or string of trap gear.

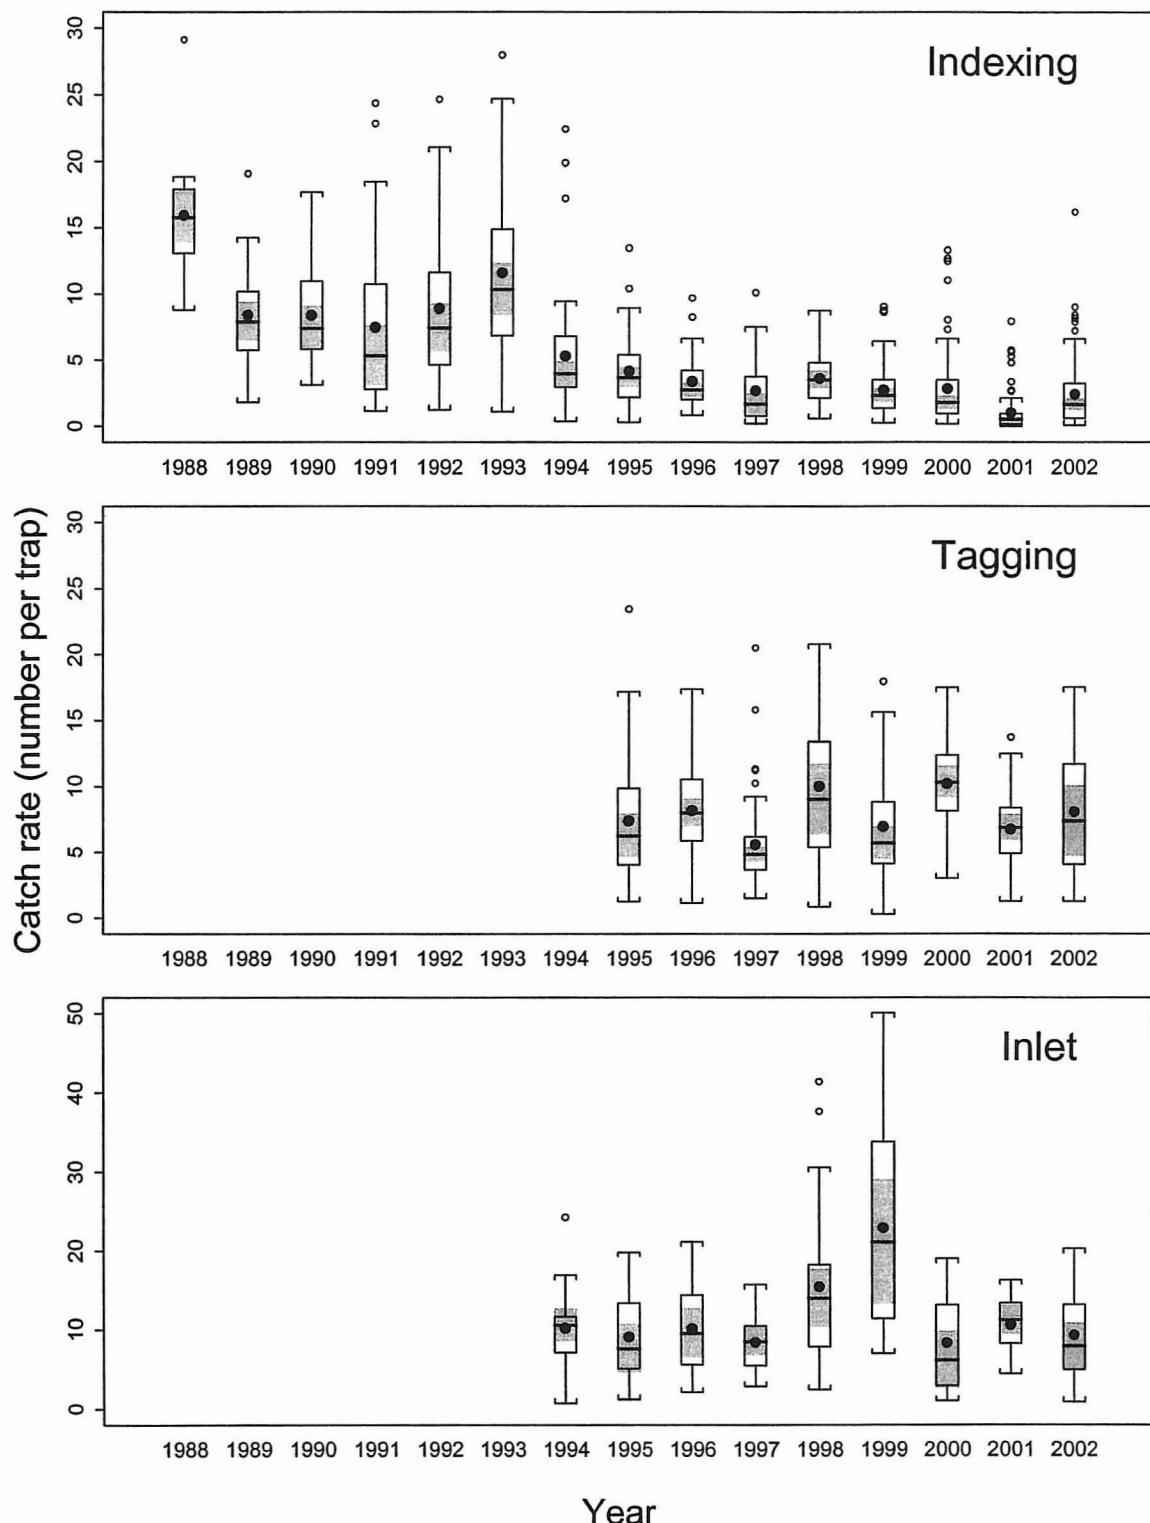

Figure 6. Distribution of catch rates for offshore indexing, tagging, and inlet sets summarised by a boxplot for each year. The filled circles show the mean annual catch rates. The shaded rectangles indicate an approximate 95 percent confidence interval on the median annual catch rate.

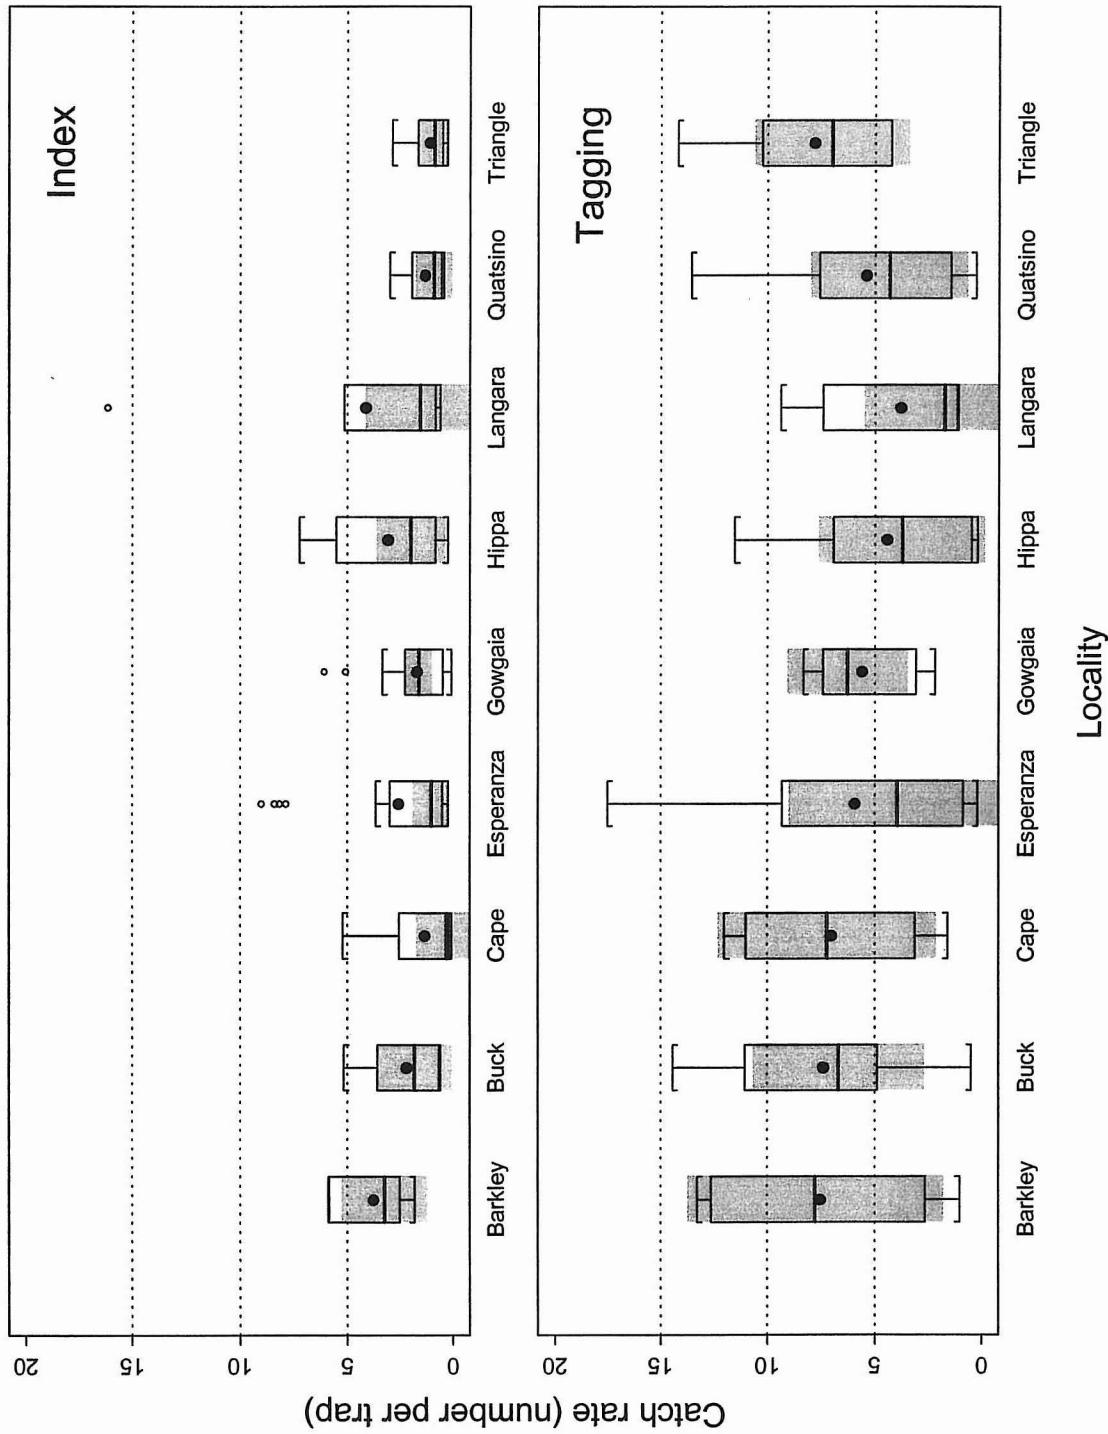

Figure 7. Distribution of catch rates for indexing and Type 2 (systematic) tagging sets summarised by boxplots for each offshore locality. The filled circles show the mean locality catch rates. The shaded rectangles indicate an approximate 95 percent confidence interval on the median annual catch rate.

APPENDIX A

DETAILS OF SETS COMPLETED DURING THE 2002 INDEXING CHARTER (PACIFIC VIKING).

Sets are listed sequentially by the start date. The locality name, the replicate, the start date and time as well as the duration in minutes are shown for each set. Position data include the Groundfish Major, Minor, and Locality coding as well as the start and end latitude and longitude in degrees and decimal minutes. The bottom depth (m) at the start and end of the set are shown. The mean bottom depth is calculated from recordings at one minute intervals between the start and end of the set. The number of traps fished is also shown and excludes only open traps, while holed or fouled traps are included. All sets were baited with approximately one kilogram of frozen squid in a bait bag in each trap.

Locality	Set	Replicate	Strata Date	Time	Duration (min)	Area	Start	End	Bottom Depth (m)	Traps Mean Fished		
							(Maj-Min-Loc)

APPENDIX B

DETAILS OF SETS COMPLETED DURING THE 2002 TAGGING CHARTER (VIKING SUNRISE).

Sets are listed sequentially by the start date. The locality name, the type of set (Type 1 traditional, Type 2 systematic or Type 3 random), the start date and time as well as the duration in minutes are shown for each set. Position data include the Groundfish Major, Minor, and Locality coding as well as the start and end latitude and longitude in degrees and decimal minutes. The bottom depth (m) at the start and end of the set are shown. The mean bottom depth is calculated from recordings at one minute intervals between the start and end of the set. The number of traps fished is also shown and excludes only open traps, while holed or fouled traps are included. All sets were baited with approximately one kilogram of frozen squid in a bait bag and 3 kg of frozen hake loose in each trap.

APPENDIX C EXAMPLE DATA FORMS.

SABLEFISH CHARTER SETTING BRIDGE LOG		
VESSEL:	PACIFIC Viking	SET NUMBER: 1
LOCALITY:	Berkeley Canyon	REASON: Index
Intended Stratum:	D1	Recorder: Malcolm
Target Depth: Minimum:	150	(fm) Maximum: 249 (fm)
SET: Date:	2002 10 5	
1 st Buoy: Number:	18	Time: 0603 Bottom Depth: 134 (fm)
Latitude:	41 23.279	Longitude: 125 59.989
1 st Anchor : Time:	008	Bottom Depth: 151 (fm)
Latitude:	41 23.279	Longitude: 125 59.989
SETTING BOTTOM DEPTH (fm/min):	161, 167, 175, 182, 191, 193, 201, 205, 207, 208	
Mean: _____ (of fm/min)		
2 nd Anchor: Time:	0620	Bottom Depth: 211 (fm)
Latitude:	41 22.647	Longitude: 126 00 270
2 nd Buoy: Number:	17	Time: 06:26 Bottom Depth: 264 (fm)
Latitude:	41 22.156	Longitude: 126 00 504
COMMENTS:	A little late on the 18 th anchor position & time	

Figure C.1. Example of a completed bridge log data form used on the 2002 survey. This form was completed from the bridge as each string was set.

COMMENTS:																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																												

Sample Type:
 1 = total catch
 2 = random
 4 = selected
 9 = juveniles
 10 = adults

Tag Type:
 10 = anchor
 20 = suture
 30 = Peterson disc

Tag Check:
 null = tag number not verified
 0 = tag number verified and corresponds to fish data
 1 = tag number may not correspond to fish data

Error:
 B = tag broken, not used
 D = dead fish, tagged
 P = paired tag, sequential tags in same fish
 N = tag not well implanted
 L = loose tag
 T = tight tag
 R = release of OTC from hole
 U = unknown length
 =

Injury:
 A = damage from amphipods
 B = bleeding
 C = cuts or fresh wounds
 D = fish dropped on deck
 E = eyes cloudy, blind
 F = fin damaged
 H = missshapen fish
 L = scale loss
 N = scrapes and abrasion
 O = bleeding at OTC hole
 R = raw wound around tag
 S = scar of healing wound
 T = tail damaged
 =

Figure C.7. Example of a completed tagging form used during the 2002 survey.

APPENDIX D SABLEFISH GONAD MATURITY STAGES

Maturity Stage	Code	Males	Females
Immature 1	01	very thin string-like >1 mm thick, translucent white colour	thin string-like =1.5mm thick mid-section, translucent-white colour
Immature 2	02	thin string-like 3mm thick, extends length of cavity, white-translucent colour	thickened >5mm, does not extend length of cavity, some folds sausage like translucent-white colour
Ripening 1	03	thick >10mm visible folds, white smooth texture, =20% body cavity	eggs present, white opaque colour encased in translucent sock, <25% of body cavity
Ripening 2	04	as above but with blood vessels present on surface, >30% body cavity	eggs larger =1mm diameter, white in colour, blood vessels present on surface, >25% of body cavity
Ripe	05	as above blood vessels present, folds delicate, some sperm may flow, >40% of body cavity	eggs at least 1mm diameter, white in colour, gonad full size, >50% of body cavity
Ripe 1	06	no stage in males	gonad same size as above but at least 25% of eggs have become translucent
Ripe 2	07	no stage in males	gonad same size as above but at least 50% of eggs have become translucent
Running Ripe	08	lobes fully developed, sperm is released when slight pressure is applied to external posterior region of body cavity	stream of translucent eggs released when slight-moderate pressure is applied to external posterior region of body cavity
Spent	09	lobes or folds are bloodshot, some sperm may be present when moderate pressure is applied to external posterior region of body cavity	gonad is red-purple in colour, residual eggs may be present, outer wall of gonad flaccid
Resorbing	10	no stage in males	eggs present but did not function normally (not normal)
Recovering	11	lobes flat, brown in colour, bloodshot appearance on edges and ends of lobes	still some red purple colour, not flaccid, whitish sheen to exterior surface
Resting	12	firm, light brown colour, some wrinkles on surface	smooth elongated and round in shape, brown purple pulp interior, exterior surface has whitish sheen

APPENDIX E
DETAILS ON SABLEFISH CATCH AND NUMBERS RECOVERED, SAMPLED AND TAGGED
DURING THE 2002 INDEXING CHARTER (PACIFIC VIKING).

APPENDIX G: TRAP GEAR GLOSSARY

This appendix describes the typical longline trap fishing gear deployed during sablefish research and assessment surveys. Slight variations in parameters such as rope length and diameter exist between these descriptions and the gear on any specific charter vessel.

Anchor: Bundle of chains weighing approximately 40 kg (90 lb) that are attached to the groundline on the becket before the first trap and after the last trap. Prevents drifting and sliding of the groundline.

Anchorline or buoyline: A 22 mm (7/8 in.) 3-ply polypropylene rope permanently attached to the groundline at the first and last becket. This line retrieves the anchor and groundline. The length depends on the depth of the set.

Baitbag: 15 x 20 cm (6 x 8 in.) 3.175 mm (1/8 in) mesh bag with a nylon drawstring and no. 72 stainless steel halibut longline snap.

Becket: 13 mm (½ in.) diameter 2 in 1 braided nylon rope spliced into the groundline every 46 m (150 ft). Each becket forms a loop of approximately 15 cm (6 in.).

Buoy: 60 to 90 cm (2 to 3 ft) diameter Bright orange inflatable plastic bladders used in combinations of two or three to suspend the sinkerline and buoyline.

Bridle: 13 mm (½ in.) 3-ply polypropylene rope "double" fastened at three points to the top hoop of the trap and knotted at a single point to form a loop of approximately 158 cm (62 in.) long with a snap bent on to the end. This bridle is fastened onto the top hoop in such a manner that pressure is inward on the tunnel when the trap is being retrieved.

Drum: Large capacity spool or drum that stores 3 to 5 complete anchor and groundline combinations.

Escape panel: 12 meshes of the trap web located in the upper half of one of the panels opposite the tunnel and cut along the horizontal bar to make a triangular opening of approximately 25 cm (10 in.) when allowed to hang loose. The cut is laced closed with a single piece of 2 mm cotton "butcher" twine. The purpose of the panel is to open when the cotton twine rots if the trap is lost while fishing, i.e. to prevent ghost fishing.

Flagpole: Attached to buoys and helps to locate the end of the string.

Groundline: 22 mm (7/8 in.) 3 ply polypropylene rope, length depending on the type and depth of the set.

Hauler or power block: Hydraulic powered pulley that hauls all the line (approximately 30 m (100 ft) per minute) aboard the vessel prior to winding or storing on the drum.

Ring: 52 mm (2 in.) diameter 8 mm (5/16 in.) stainless steel ring bent or knotted onto becket.

Shotline: Additional pieces of 22 mm (7/8 in.) polypropylene rope used to extend the anchor or buoyline, usually 91 m (50 fm) or 183 m (100 fm) long.

Sinkerline: 19 mm (¾ in.) 3-ply nylon rope attached to the top of the buoylines or shotlines. The purpose of this line is to prevent the polypropylene anchor or buoyline from floating and "puddling" on the surface and posing a hazard to navigation. The line is usually 91 m (50 fm) or 183 m (100 fm) long.

Snap: Steel device with ring on one end and a spring loaded enclosure on the other end strong enough to withstand a 1400 kg (3000 lb) strain.

Traps: The traps are a Korean design adopted and modified by local fishers to local conditions.

They are designed and constructed to stack into each other when transported or stored. The traps are constructed of mild steel rod welded at all junctures. The top hoop diameter is 84 cm (33 in.), the bottom hoop diameter is 137.2 cm (54 in.), and the 6 vertical members are 79 cm (31 in.) long giving the trap a 74 cm (29 in.) vertical height. Horizontal bars are attached midway between the top and bottom hoops in 5 of the 6 vertical panels. The trap is covered or capped with a single piece of black nylon 70 mm (#42) web (stretch measure inside the knots). This is fastened to the frame so that the top is permanently closed and the bottom can be opened and closed with a draw string. The one side panel without a horizontal bar is not covered with web and accommodates the trap entrance or tunnel. The tunnel is constructed of two pieces of green 44 mm (#18) knotless braided web. The two seams of the tunnel are fastened together prior to attaching to the frame of the trap. When the tunnel is fastened to the trap it slopes downward with a 36 cm (14 in.) opening or slit. The bottom part of the slit will be taut and the top will be loose when the tunnel is stretched into place from the opposite panel of the trap. The tunnel extends 64 cm (25 in.) into the trap. When the trap is prepared for fishing both the tunnel lines and the bottom closing line (4 mm braided single-ply polypropylene twine) are pulled taut, looped together and knotted at a single point. The tunnel and bottom closing lines are of sufficient length to allow the bottom and the tunnel to collapse completely against the inside of the trap to allow for stacking. One pf the panels opposite the tunnel contains the escape panel (defined above). Chafing line (10 mm (3/8 in.) and 13 mm ($\frac{1}{2}$ in.) diameter 3-ply polypropylene) is wrapped around all the frame members to protect the web after the trap is covered.

(Descriptions were modified from Smith et al. 1996)
