ABSTRACT

Cobb, D.G., and J.F. Flannagan. 1987. Aquatic Invertebrate Survey of the Dauphin Lake, Manitoba Drainage Basin, 1982. Can. Data Rep. Fish. Aquat. Sci. 625: iv + 16 p.

An aquatic invertebrate baseline survey of the major rivers entering Dauphin Lake, Manitoba was conducted in 1982. Descriptions of sample stations, results of physical/chemical data, and seasonal densities of aquatic invertebrate orders are tabulated.

Key words: rivers; aquatic invertebrates; Ekman dredge; surber; nutrients elements.

RÉSUMÉ

Cobb, D.G., and J.F. Flannagan. 1987. Aquatic invertebrate survey of the Dauphin Lake, Manitoba Drainage Basin, 1982. Can. Data Rep. Fish. Aquat. Sci. 625: iv + 16 p.

Une étude de base des invertébrés aquatiques des principales rivières qui se jettent dans le lac Dauphin, au Manitoba, a été effectuée en 1982. On y présente les postes d'échantillonnage, les résultats des données physiques et chimiques et les densités saisonnières des ordres d'invertébrés aquatiques sous forme de tableaux.

Mots-clés: rivières; invertébrés aquatiques; benne prenante Ekman; Surber; éléments nutritifs; éléments.

INTRODUCTION

In 1982, an aquatic invertebrate survey was conducted in the Dauphin Lake, Manitoba drainage basin. This study, part of a larger research program by the Canada Department of Fisheries and Oceans to study techniques for the rehabilitation of declining Canadian fisheries is a co-operative pilot project with the Manitoba Department of Natural Resources. The walleye *Stizostedion vitreum vitreum* (Mitchill) fishery on Dauphin Lake, is the focus of the present program (Flannagan et al., unpublished). This fishery is valuable both commercially and for sport and information gained from this pilot study can be applied to fisheries on large lakes, eg. Lake Winnipeg.

Increased agricultural development in the last 50 years has led to extensive ditching, channelization and land clearing, all of which contributed to changes in the aquatic ecosystem in the form of increased siltation, substrate instability, and higher peak discharges in the spring (Hill 1980; Dance and Hynes 1980). Lack of reproductive success of walleye in the Valley River, a tributary of Dauphin Lake, has been attributed to physical disturbances such as sedimentation and changes in intensity and duration of spring run-off (Gaboury 1985). The purpose of the 1982 stream survey was to identify species of aquatic invertebrates which by their presence, absence or abundance could be used as indicators of poor habitat (pollutants, sedimentation, substrate instability, etc.). Presence or absence of these indicator species in rivers flowing into Dauphin Lake that are used by spawning walleye could then be used to provide possible reasons for poor spawning success of the walleye. The baseline survey would also provide a reference point for future stream rehabilitation studies.

This report presents the physical/chemical data collected in the 1982 survey and presents data on the densities and distribution of orders of aquatic invertebrates occurring in the Dauphin Lake drainage basin. Further analysis of selected orders at the species level will appear in another report.

METHODS

DESCRIPTION OF THE STUDY AREA

Dauphin Lake, situated in west-central Manitoba ($51^{\circ}17'N$, $99^{\circ}48'W$) is a remnant of glacial Lake Agassiz. Babaluk et al. (1984) provide descriptions of the lake and its fishery. The drainage basin of the lake (Fig. 1) with an area of 8700 km^2 consists of seven permanent rivers originating in the Duck Mountain Provincial Park to the north-west and the Riding Mountain National Park to the south and southwest. These "mountains" are actually part of the Manitoba escarpment marking a former border of glacial Lake Agassiz. Numerous other small creeks and ditches in the Dauphin Lake drainage basin flow intermittently during and shortly after spring thaw.

Table 1 provides a description of the major rivers in the drainage basin. More detailed descriptions of the drainage basin are found in Cobb and Flannagan (personal communication).

FIELD SAMPLING PROCEDURES

Three stations were sampled on each of the seven rivers (Fig. 1). "Mouth" stations were situated approximately 100 M upstream from the lake. The "downstream riffle" stations were situated as close to the lake as possible, upstream from the influence of seiches from the lake. The "upstream riffle" stations were located as far from the lake as possible but before the rivers branched into lower ordered streams arising in the Parks. These upstream stations were above any major anthropogenic perturbations associated with agricultural development (land clearing, channelization, etc.) known to influence stream biota.

Mouth and riffle stations were visited monthly from May to August and May to September, 1982 respectively. On each sampling date, three replicate, random samples were taken. At the mouth stations, a tall FRB Birge-Ekman grab (Burton and Flannagan 1973) (0.0225 m^{-2}) with an automatic release closing mechanism (Burton 1974) was used and samples were sieved through a $200 \mu\text{m}$ mesh. At the riffle stations a Surber sampler (0.0929 m^{-2}) with a $200 \mu\text{m}$ mesh was used. All samples were preserved in 10% formalin, later washed, sorted to taxonomic order and stored in 70% ethanol. Specimens of Trichoptera, Ephemeroptera and Plecoptera were sorted to lowest taxonomic level for later analysis.

On each sampling date, air and water temperature were recorded (hand held thermometer), and water samples were taken for same-day laboratory analysis of: pH (Radiometer pH meter model #29 pH), conductivity (Radiometer conductivity meter, model #CDM 2C), and dissolved oxygen (Winkler titration method). At the mouth stations, depth, turbidity (loss of light at 10 cm) and type of substrate were recorded. At each riffle station velocity (Ott current meter) was measured and substrate type was characterized.

Additional data (discharge, total suspended solids) were obtained from the sediment data report given in Canadian Rivers 1982 (Environment Canada 1984). Stream order and approximate drainage area above each station were determined using planimetry on a 1:50000 scale topographic map.

DATA PRESENTATION

The physical/chemical data are reported in Tables 2 and 3, and analysis for major nutrients and elements from before and after spring runoff are presented in Tables 4 and 5. In addition to the discharge and total suspended solids (tss) which were measured at sample times (Table 3), Fig. 2-5 present the spring peak of

discharge and tss, to give an indication of the magnitude of runoff for each river. At the mouth stations an indication of turbidity is given for late spring and early summer as loss of light at 10 cm (1.0.1).

The density of aquatic invertebrate orders is given in Table 6 for the mouth stations and Table 7 for the riffle stations. These data are in the form of the mean number per square meter for three replicates at each sample time.

ACKNOWLEDGMENTS

The authors thank K. Donkersloot, G. Friesen, M. Haworth-Brockman, and L. Ross who assisted in the collection of samples and who persevered through sorting samples in the laboratory, Mrs. G. Dectorow who typed the report and Mr. A. Wiens who reviewed the report and suggested improvements.
