# SUMMARY OF THE 1990 COHO SALMON SMOLT TRAPPING OPERATIONS ON THE LACHMACH RIVER, BRITISH COLUMBIA 

## by

D. L. W. Davies

Biological Sciences Branch<br>Department of Fisheries and Oceans<br>Pacific Biological Station<br>Nanaimo, British Columbia V9R 5K6

Davies, D. L. W. 1991. Summary of the 1990 coho salmon smolt trapping operations on the Lachmach River, British Columbia. Can. Data Rep. Fish. Aquat. Sci. 832: 53 p.

A permanent welded aluminum smolt fence was used to capture smolts at the mouth of the Lachmach River, east of Prince Rupert, British Columbia, between April 12 and June 6, 1990. A total of 25,860 coho smolts was captured. Of these, 24,639 smolts were coded wire tagged and adipose fin clipped. Totals of 1,189 rainbow trout, 1,964 Dolly Varden, 1,387 sculpins and 9 cutthroat trout were also captured.

RESUMÉ

Davies, D. L. W. 1991. Summary of the 1990 coho salmon smolt trapping operations on the Lachmach River, British Columbia. Can. Data Rep. Fish. Aquat. Sci. 832: 53 p .

Une barrière permanente en aluminium soudé a été utilisée pour capturer des smolts à l'embourchure de la rivière Lachmach, à l'est de Prince Rupert (Colombie-Britannique), entre le 12 avril et le 6 juin 1990. Un total de 25860 saumons cohos ont été capturés. De ce nombre, 24639 smolts one été étiquetés au moyen de fil de fer codé et leur nageoire adipeuse a été coupee. On a également capturé un total de 1189 truites arc-enciel, l 964 Dolly Varden, 1387 chabots et neuf truites fardées.
-

## INTRODUCTION

The Lachmach River Project is part of the Coho Salmon Research Program which was initiated in response to the Canada-U.S. Pacific Salmon Treaty. The Program obtains information on the biology and productivity of coho salmon (oncorhynchus kisutch) stocks in British Columbia. The Lachmach River Project was set up in the spring of 1987 to obtain information on northern B.C. coho salmon stocks. Data have been collected each spring beginning in 1987, (Table 1) (Finnegan et al. 1990 ; Finnegan 1990 ; Davies 1991).

The Lachmach River is located 23 km . east of Prince Rupert, B.C., at the head of Work Channel (Fig. 1). This report presents data from fence operations, coho smolt trapping and sampling, and coded wire tagging operations conducted in the spring of 1990.

## METHODS

The permanent aluminum smolt fence used on the Lachmach River in 1990 was described in detail in the 1988 spring data report (Finnegan 1990). The only change to the fence in 1990 was the modification of the upstream trap to improve the capture of migrating adult steelhead trout (oncorhynchus mykiss).

A temporary smolt fence was installed on the upper Lachmach River immediately downstream of the 5000 m pond (Fig. 2). This fence was also described in detail in both the 1988 and 1989 data reports (Finnegan 1990 ; Davies 1991).

A $2 \times 3$ inclined plane trap (Conlin and Tutty 1979) was installed 50 m upstream of the main fence to collect data on fish that were small enough to swim through the fence such as coho and pink fry (oncorhynchus gorbuscha). The trap was tethered by a 1/4 inch cable to another $1 / 4$ inch cable spanning the river. Each evening, the trap was pushed out into the main flow of the river into fishing position and left to fish overnight. Every morning the trap was emptied of fish and pulled to the side of the river out of fishing position for the remainder of the day.

The fish captured in the trap were counted separately and then pooled with the fish caught at the main fence, and were sampled and tagged using the same method as the fence caught fish.

Every day at the main fence, fish were sorted by species, enumerated, sampled and checked for marks. Random samples were obtained by two different methods. Method 1 involved rapidly moving a small dipnet through the fish in the trap box and scooping up a netful of fish until approximately 100 fish or about $10 \%$ of the total catch was removed. Method 2 involved taking every third dipnet of fish and putting them in a separate bucket until 100 fish
were obtained. Samples were anaesthetized with 2 -phenoxyethanol and measured for fork length and weight. Fork lengths were measured on a smolt board to an accuracy of 0.5 mm . Weights were measured on an Ohaus Port-O-Gram balance to an accuracy of 0.05 g . Selection for scale sampling for age analysis was done by selecting smolts from 5 mm size groups from 40 mm to 170 mm and attempting to get 14 scale samples from each group throughout the smolt run. Fin clips, brands and any unusual condition (ie. deformities, injuries, etc.) were recorded. All clipped, branded and unusually large or small fish (whether within the random sample or not) were measured for length and weight and had scales taken.

At the 5000 m fence, all fish were counted, checked for marks and measured to an accuracy of 0.5 mm . All coho juveniles were given an upper caudal fin clip.

All mortalities were recorded by species, sexed, and measured for fork length and wet weight. Scales, otoliths and fin rays were taken from some of the dead fish for age analysis.

All coho smolts captured at the main fence were anaesthetized with 2-phenoxyethanol, adipose fin clipped and coded wire tagged with standard tags (Northwest Marine Technologies, Shaw Island, WA. ; Mk II Tagging Unit). Coho smolts were divided into two groups, larger and smaller than 85.5 mm , and were tagged with different tag codes. This size was selected as the best length to separate age 1.0 and 2.0 smolts based on age-length analysis in 1989 (Davies, 1990). Fish smaller than 60 mm were too small to tag and were released untagged and unclipped. Tag codes for large coho were 08/26/30, 08/27/19, 08/27/18. Tag codes for small coho were $08 / 26 / 34$ and 08/27/07.

After each day of tagging, a maximum sample of 100 tagged fish from each size group was held overnight. The next day these fish were put through the metal detector of the quality control device to see which fish had lost their tags. All fish that had lost their tags were retagged before release.

Two groups of one hundred smolts were marked and released 50 $m$ upstream of the main fence to assess the fence's capture efficiency. Recaptures of marked fish were recorded at the main fence and the recapture rate was used as an indication of fence efficiency. The first group consisted of 10 small and 90 large CWT smolts that were upper caudal clipped and released on May 3. The second group consisted of 50 CWT smolts of each size group which were upper and lower caudal clipped and were released on May 14.

Adult steelhead were counted through the fence either by dipnetting them from the trap or from behind the fence nosecones and passing them over the top of the fence or by opening a gap in the fence panel and letting them swim through.

Daily records were kept of cloud cover, precipitation, water temperature, air temperature and water level. Observations were generally taken at 0800.

## RESULTS

## MAIN FENCE

Coho
The Lachmach River smolt fence was in almost continuous operation for 55 days in 1990. High water conditions on May 6 forced the field staff to remove the fence panels at 0945 hrs on May 6. They were not replaced until 1330 hrs on May 7. Totals of 25,860 smolts were caught during fence operations (Table 2). 24,639 smolts, or $95.3 \%$ of the total run were coded wire tagged and released alive, while 504 were mortalities. Smolts released untagged totalled 717 and included fish too small to be tagged (fish less than 65 mm were too small to fit in the smallest head mold for the tagging machine), fish that escaped from the tagging shed before being tagged and any moribund or injured fish. Large smolts (larger than 85.5 mm ) comprised $84 \%$ of the total smolt run (Table 3). Coho smolts that were sampled totalled 3,995 or 15.7\% of the total run (Table 4). The run peaked on May 15 with a secondary peak on May 21 (Fig 3).

An unknown number of smolts passed the fence uncounted during the flood conditions of May 6-7. If the smolt numbers on May 6 (448) and May 8 (503) are averaged, then an estimate of 475 smolts passing the fence on May 7 can be obtained. After the water receded on May 7,106 smolts were found in the trap boxes. Of the estimate of 475 smolts migrating on May 7,106 were captured and the remaining 369 smolts can be assumed to have passed the fence uncounted (Table 2).

The results of the fence efficiency tests indicated that the recapture rate for early migrants was $82 \%$ and for peak migrants was 94\% (Table 5). These results indicate a high efficiency if one takes into account the fact that marked fish released upstream of the fence do not necessarily migrate downstream during fence operations and that released fish may experience some handling and stress related mortality. Some of the early test fish may have passed the fence undetected during the freshet on May $6-7$ when the panels were removed.

Tag retention tests indicated a $1 \%$ loss of tags for both large and small smolts. If this loss rate is applied to the total numbers of fish tagged, then 3926 small smolts and 20,466 large smolts would be expected to have retained their tags after 24 hours. Tag retention tests over 48 hours were conducted in
previous years and indicated no additional tag loss.
Small smolts were tagged with 2 tag codes; 08/26/34 until May 14 and 08/27/07 from May 15 to the end of the study (Table 6). Large smolts were tagged with 3 tag codes; 08/26/30 until May 8, 08/27/19 from May 8 until May 19 and 08/27/18 after May 19.

Selection of smolts for sampling was conducted using two different methods. Method 1 involved rapidly moving a dipnet through a large bucket of fish and selecting the first 100 fish scooped. Method 2 involved selecting fish from every third dipnet until 100 smolts were obtained. Sampling results from each method were kept separate. Results from the two sampling methods are shown in Table 4 and the length frequencies are compared in Figure 4. The results show that Method 1 and Method 2 produced very similar results. Average lengths and weights using Method 1 were $93.1 \mathrm{~mm}(\mathrm{SE}=0.22, \mathrm{~N}=2,586)$ and $7.54 \mathrm{~g}(\mathrm{SE}=0.07, \mathrm{~N}=2,057)$. Average lengths and weights using Method 2 were 92.9 mm ( $\mathrm{SE}=0.23$, $\mathrm{N}=1,409)$ and $7.44 \mathrm{~g}(\mathrm{SE}=0.09, \mathrm{~N}=1,326)$. The overall average length was 93.1 mm and the average weight was 7.50 g . The length frequency graphs are very similar except for the difference in total number sampled with each sampling method (Figure 4).

A number of smolts with mutilation type marks were recaptured at the main fence (Table 7). Most of the marked fish recaptured were marked in the late summer and early fall of 1989 as part of a study to determine juvenile coho movements within the system. The largest number of marked fish recaptured at the main fence were right ventral clipped fish from the 5000 m ponds, marked in the summer of 1989. As none of these fish were captured at the 5000 m fence during the present study period, it is likely that these fish moved out of the 5000 m ponds and into other areas of the system in the fall or winter before the 5000 m fence was installed on April 21. A total of 109 left maxillary clipped fish were marked in 1989 at the main fence after tagging ended on June 5 and 13 were recovered in 1990 at the main fence. These 13 fish probably stayed in the estuary for the entire year. The upper caudal fin clipped fish were marked at the 5000 m fence during the 1990 study period and only 133 were recovered at the main fence out of a total of 259 marked.

Twenty one adipose clipped smolts were captured at the main fence in 1990. Fourteen of these smolts had a coded wire tag. Coded wire tags were recovered and analyzed from the heads of five of these smolts. Four of the smolts were from 1990 tag groups (3 from $08 / 27 / 19$ and 1 from 08/27/18) and one was from a 1989 tag group ( $08 / 26 / 47$ ). It is unknown how the 1990 marked smolts were captured in the trap boxes. It is possible that they were able to swim upstream through the fence. The 1989 tagged smolt could have swum upstream of the fence prior to fence installation on April 13.

Coho smolt mortalities totalled 502 during the study period.

These consisted of 337 mortalities found in the trap boxes, 85 found dead after the 24 hour tag retention tests, 61 killed during the tagging process, and 19 killed to observe tag placement. Most of the mortalities had scales, fins and otoliths taken from them for age analysis.

A total of 337 scale samples and 79 fin and otolith samples were taken from coho smolts for age analysis. Of these 44 (13.0\%) could not be aged due to scale regeneration or poor samples, 95 (28.2\%) were analyzed as age 1.0, 189 (56.1\%) as age 2.0 and 9 (2.67\%) as age 3.0 (Table 8). Difficulties arose with age determination due to the uncertainty of what constituted an annulus with some of the scales from fish with lengths near the upper and lower size limits for each age, (S. Maclellan, P.B.S. Scale Lab, pers. comm.). Comparisons of the three aging methods showed that there was good agreement between all structures (Table 9). There is a slight indication that when there is disagreement between structures that the otolith ages are greater than both fin and scale ages. Age compositions estimated from scales are unlikely to be in error except for age 3.0 fish which may be fewer than estimated.

The mean lengths of age $1.0,2.0$ and 3.0 smolts were 77.0 mm , 107.1 mm and 123.1 mm respectively. The length frequency histogram shows that the lengths of age 1.0 and age 2.0 smolts overlap between 75 and 100 mm . (Fig. 5).

An estimate of the age composition of the migrating smolts was obtained by first calculating the proportion of each age within 1 mm length classes. Then each proportion was multiplied by the total number of smolts within each class to get the number of smolts by age in each length class. The numbers were then summed by age over all to obtain the numbers of smolts by age. These results showed that 7,525 (29.1\%) were age $1.0,18,102$ ( $70.0 \%$ ) were age 2.0 and 34 ( $0.9 \%$ ) were age 3.0 .

## Other Species

Totals of 1,189 rainbow/steelhead (O. mykiss) trout juveniles, 1,964 Dolly Varden (Salvelinus malma) juveniles, 1,387 cottids (Cottus sp.), 9 cutthroat trout (O. clarki) juveniles, 20 coho fry and 11 pink ( 0 . gorbuscha) fry were captured moving downstream (Table 10). Coho and pink fry were able to swim through the fence panel screen mesh and therefore were only occasionally caught in the trap boxes.

Numbers of trout juveniles migrating downstream were increasing when the fence was pulled out while migrating Dolly Varden juveniles peaked in mid May (Fig. 6). Both cottid and upstream migrating adult steelhead numbers appeared to peak in early May. Steelhead kelt numbers were still high when the the
fence was taken out.
Tables 11 and 12 show the average fork lengths and wet weights of fish other than coho smolts. Length frequencies for rainbow trout, Dolly Varden and cottids are presented in Figures 7, 8 and 9 respectively.

We counted 334 adult steelhead passing the fence moving upstream and 93 kelts going downstream. The numbers of steelhead moving upstream is only a minimum number as there were probably more fish that passed the fence without being observed. When there were many steelhead observed holding below the fence, a few panels were lifted to allow free steelhead passage. During these periods attempts were made to count as many steelhead as possible, but the demands of smolt sampling and tagging precluded a complete count. Adult steelhead could also have passed the fence unobserved before the fence was installed on April 13, during the flood event on May $6 / 7$ and after the fence was taken out on June 6. The downstream steelhead kelt number is a minimum also as some kelts could have moved after the fence was taken out. On the evening of June 3 many kelts were observed holding upstream of the fence and a small amount of rain had raised the river level slightly. Three panels were lifted and 90 kelts were counted past the fence in a 2 hour period.

## INCLINED PLANE TRAP

Fish numbers caught in the $2 \times 3$ trap are presented in Table 13. The trap was fished intermittently on 31 nights whenever time and manpower permitted. When the trap was fished, the coho smolt catches were weakly correlated ( $r=0.75$ ) with smolt catches at the main fence (Fig. 10). The effectiveness of inclined plane traps is known to depend on variables such as fishing position, water height, and water clarity.

Pink fry appeared to be either at their peak or past their peak when the trap was installed on April 11. Coho fry started appearing on May 21 and were still showing up when the trap was pulled out on June 8.

## 5000 M FENCE

The 5000 m fence was continuously fishing for 47 days from April 21 to June 7 except for a period of about 30 hours during the flood event of May $6 / 7$ when water topped the panels and lifted the breakaway panels. Totals of 259 coho smolts, 3 rainbow/steelhead juveniles, 2 Dolly Varden juveniles, and 2 cutthroat trout juveniles were caught (Table 14). All of the coho smolts received an upper caudal clip and were released.

## ENVIRONMENTAL DATA

Precipitation was generally low during the study period with the exception of one peak on May 6 and 7 when 90 mm of rain fell (Fig. 11). Total precipitation for the study period was 230 mm . Maximum and minimum air temperatures varied from a low of -2.5 deg . C on Apr. 30 to a high of 23 deg. C. on May 28 (Figure 12). On May 30 the min.-max thermometer ceased operating and spot temperatures were taken using a standard thermometer. Water temperatures gradually increased from a minimum of 4 deg . C to a maximum of 12 deg. C. (Figure 13).

ACKNOWLEDGEMENTS
The data was collected under a contract to J.A. Taylor and Associates of Sidney, B.C.

a Random samples were obtained in two ways. Method 1 involved selecting the first 100 fish that were dipnetted, Method 2 involved selecting fish from every third dipnet until 100 were obtained.
b
Method 1 was used to select all fish from Apr. 13 until May 17 On May 17, 101 fish were selected using Method 1 and 109 fish were selected using Method 2. Method 2 was used to select fish from May 17 until May 30, after this time all fish were selected with Method 1.

| :---: |

a all fish except the upper caudal, left maxillary and old upper and lower caudal marked fish were marked in the late summer and early fall 1989.
b left maxillary clipped fish were marked at the camp fence from June 6 to June 16 in 1989.
$c$ upper caudal marked fish were marked at the 5000 m fence during the 1990 study period.
d old upper and lower caudal marked smolts were marked in various locations within the watershed to obtain local population estimates.

Lachmach River, 1990

[^0]:    a most coho and pink fry were able to swim through the fence screens and thus were not captured.
    b the numbers of adult steelhead migrating both upstream and downstream are both minimum numbers. Migrants were able to pass undetected both before and after the fence was installed and during periods when fence panels were lifted to allow steelhead passage.
