ABSTRACT

Zitko, V. 1982. LETCUR, the lethality curve program. Can. Tech. Rep. Fish. Aquat. Sci. 1134, iii + 10 p.

A BASIC program is described to express LT50 (time to 50% mortality) as a three-parameter (K2, A, B) function of toxicant concentration (CW): $LT50 = -\ln(A-B/CW)/K2$. A calculator program, published previously, is documented to facilitate its portability.

Key words: aquatic toxicology, acute toxicity, computer program

RÉSUMÉ

Zitko, V. 1982. LETCUR, the lethality curve program. Can. Tech. Rep. Fish. Aquat. Sci. 1134, iii + 10 p.

Le présent rapport contient la description d'un programme BASIC permettant d'exprimer le TL50 (temps requis pour 50% de mortalité) comme fonction à trois paramètres (K2, A, B) de la concentration du toxique (CW) : $TL50 = -\ln(A-B/CW)/K2$. Une référence à un programme machine déjà publié en facilitera la portabilité.

INTRODUCTION

Lethality curves, graphs of time to LT50 plotted vs CW, are used widely in aquatic toxicology. They present graphically the "dose-mortality" relationship and are extrapolated frequently to estimate the incipient lethal level (lethality threshold).

The function

$$LT50 = -\ln (A-B/CW)/K2$$

has been suggested for the lethality curve (Zitko 1979). This suggestion was based on the one-compartment model of uptake of chemicals.

Expressing the lethality curve in this manner has several advantages over the usual plotting and storage of the graphs. The data are condensed into three parameters and may be stored readily in a data base. Comparison of the values of the parameters for a number of chemicals may lead to the development of structure/lethality relationships. Such comparisons are practically impossible or are at best only qualitative, when based on a visual comparison of graphs. In addition, incipient lethal levels are given consistently by the ratio A/B. Finding the values of the three parameters is straightforward but time-consuming, since it involves searching for a value of K2 which yields correlation coefficient $R < -0.9$ between $EXP(-K2*LT50)$ and $1/CW$. For each selected value of K2, linear regression must be calculated to obtain the corresponding values of the parameters A and B.

The original paper (Zitko 1979) contains a program to perform the calculations on the HP29C programmable calculator. The program has not been documented and, since the HP29C is no longer a common calculator, the transfer of the program to other calculators presents problems. A detailed documentation is given in this report to make the program easy to implement on any programmable calculator.

The main part of this report contains documentation of the program LETCUR, written in HP Terminal BASIC. The program calculates values of the three parameters and plots the lethality curve as well. The parameter calculation part is readily transferable to any computer with a reasonably "standard" BASIC interpreter. On the other hand, the plotting part may require considerable rewriting, although the algorithms, such as those for plotting logarithmic scales and data scaling, are generally applicable.

LETCUR also contains a "convenience" routine for the calculation of mean concentration of the toxicant if, as is the case in most static experiments, the concentration decreases exponentially with time. The routine also provides for the usual practice of changing the toxicant solution at 48 h of exposure.

PROGRAM LETCUR

In the attached listing, the calculation of the parameters K2, A, and B is performed by statements 100-765 and 3000-3150, the latter

containing the linear regression subroutine. A major part of the listing (statements 770-1380) deals with plotting the lethality curve. Statements 4500-5010 are used optionally to calculate the mean concentration of the toxicant and to display the concentration vs time curve.

The arrays dimensioned in statement 100 are used as follows: C(20) toxicant concentrations, T(20) LT50's, G(20) calculated LT50's, Z(20) scaled logarithms of toxicant concentrations, D(20) logarithms of LT50's. The arrays may be expanded, but there are seldom more than 20 points in lethality tests.

Concentration units should be chosen so that the values are >1 . This is because of the plotting format used. For the same reason, experimental data must be entered in decreasing order of concentration. In autoscaling (statements 845-960) the program assumes that the first and last toxicant concentration entered are the highest and the lowest, respectively.

The search for the optimum value of K2 is performed in three stages: First (statements 205-300) a preliminary value is found, which gives a correlation coefficient $R < -0.9$. Then (statements 320-435) the interval containing the optimum value is obtained. Finally (statements 460-640) the interval is narrowed to within 1% of the optimum K2 value. The whole algorithm is a generally applicable "one-dimensional" optimization. A convenient starting value of K2 is usually $K2 = 1$, but there is the option for the user to start with any value (statement 210). On completion of the optimization, values of the parameters K2, A and B, table of toxicant concentrations, experimental and calculated LT50's, and the incipient lethal level are printed (statements 645-765). The linear regression used during the optimization (statements 3000-3150) uses $EXP(-K2*LT50)$ as the dependent and $1/CW$ as the independent variable. The calculations are routine otherwise.

In preparation for plotting, the program first determines whether the incipient lethal level is too close to the Y-axis and, if it is, the X-axis will be scaled to shift the incipient lethal level to the right. The variable G (statements 774 and 776) is the flag. PRINT CHR\$(141) means "clear screen" (statement 800). Logarithms of experimental LT50's and toxicant concentrations are calculated. At the same time, the former are shifted to start from 0 (log 1; statements 810-840, see also 960). Next, the numbers of logarithmic cycles needed on the axes (M on the X-axis, N on the Y-axis) are determined (statements 845-960). The loops in statements 970-1210 draw the "ticks" on the axes. This is a generally useful algorithm for plots in logarithmic coordinates.

Printing labels and scales (statements 1212-1241) completes the preparation of the graph format. The flag Q9 indicates when the shortest LT50 is less than 10 h, and the Y-axis is shifted accordingly. Experimental points are plotted by statements 1232-1260. Following this, the incipient lethal level line is drawn and labeled (statements 1266-1296). Finally, the calculated lethality curve is plotted (statements 1298-1320) and the graph is labeled by the name of the

compound, incipient lethal level, and the equation of the lethality curve (statements 1321-1328).

The described automatic graph formatting and plotting routine worked well in all of our applications. However, such automated routines tend to run into problems in some unusual or unanticipated applications. Statements 4000-4030 mean "assign source to graphics", "assign destination to plotter (HP-IB#6)", and "transfer file", respectively. Their execution results in copying the graphics display on the plotter. The listing is concluded by the optional routine calculating mean concentration of the toxicant. The calculation assumes that the concentration decreases exponentially with time. To check the validity of this assumption, the concentrations are plotted against time for a visual check. It is also possible to use only selected points for the calculation. The parameters "slope" (M) and "intercept" (C) are determined by linear regression on the linearized function $\ln(CW) = MT+C$. The concentrations should be entered relative to concentration at time $t = 0$ (statements 4500-4820). The subroutines starting in statements 4920 and 4980 draw the points and the calculated curve, respectively.

Statements 4840-4890 calculate the mean concentration. This depends on the length of exposure, that is on the LT50 at a given concentration and is calculated from the formula:

$$CW_{av} = 1/LT50 * Co * \int_0^{LT50} EXP(-M*t)*dt$$

where CW_{av} = mean concentration,
 Co = nominal concentration multiplied by intercept,
 M = slope.

The calculation assumes that the toxicant solution is changed at 48 h. Accordingly, for $LT50 < 48$ h the calculation proceeds as outlined, but for $LT50 > 48$ h the concentration is averaged to 48 h (statement 4872), another mean is calculated for the exposure time in the new toxicant solution (statement 4873) and these two means are averaged again (statement 4874). If the experiment was carried out for longer than 48 h without solution change then statement 4865 must be modified. A modification would also be required for solution changes taking place at shorter time intervals.

After completion of these calculations, the program proceeds to fit the lethality curve (statement 4910). There is no provision for sending the CW vs time graph to the plotter. If desired, this operation may be easily accomplished manually.

LETCUR ON HP29C

The documentation below is largely self-explanatory. The calculation proceeds in much the same way as in LETCUR except that the K2 search is done manually and the optimization is left completely to the judgment of the user. Also, mean toxicant concentrations are not calculated and must be entered by the user. The

program consists of five subroutines (called labels, LBL). Some are used internally by the program, others are selected by the user. LBL0 is used to enter data. The parameter search is performed by LBL1 which calls LBL2 and LBL3. Values of LT50 for given CW and fitted parameters K2, A, and B are calculated by LBL9. Great care must be exercised in proper calculator initialization for the various operations.

ACKNOWLEDGMENTS

I thank Ms. R. Garnett for editorial assistance, Mrs. J. Hurley and Mrs. B. Fawkes for typing the manuscript and arranging the report, Ms. Madelyn M. Irwin, and Ms. R. Garnett for patient proofreading. Drs. D. W. McLeese and S. Ray commented on the manuscript.

Chlordane lethality curve

Lethality curve program for HP 29C. Documentation

Initial status of the calculator:
 Register 0 (R0)=16 (address of the first indirect storage register)
 Register 8 (R8)=16 (control value)
 Y-register =first LT50 value
 X-register =first CW value

```

01  LBL0      Data Entry Routine
-----
02  1/x      Reciprocal of CW, currently in X-register
03  STO 1    Store it in R16, the first indirect
             storage register of HP 29C
04  ISZ     Increment indirect storage register by 1
05  x = y    Exchange the contents of the X- and Y-
             registers. LT50 is now in the X-register
06  CHS     Convert LT50 to -LT50
07  STO 1    Store -LT50 in R17
08  ISZ     Increment indirect storage register index
09  RTN     Return to LBL0. The calculator is ready to
             accept another pair of values (LT50, CW).
             AFTER COMPLETION OF TEST DATA ENTRY, THE
             INDIRECT STORAGE REGISTERS CONTAIN:
             R16  -0.0333 (1/30)
             R17  -0.7
             R18  -0.2 (1/5)
             R19  -1.4
             R20  -2.0 (1/0.5)
             R21  -3.3
             R22  -4.0 (1/0.25)
             R23  -4.2
             THE REGISTERS R24 - R29 ARE AVAILABLE FOR
             ADDITIONAL VALUES (HP 29C CAN ACCEPT A TOTAL
             OF 7 PAIRS)
10  LBL1     Statistical Summation Driver
-----
11  CLEAR 8  Clear the "statistical registers" R.0 - R.5.
             The statistical registers of HP 29C store
             sums used in statistical calculations:
             R.0  n (number of entries)
             R.1  S(x)
             R.2  S(x^2)
             R.3  S(y)
             R.4  S(y^2)
             R.5  S(x*y)
             S (sigma on HP 29C) stands for sum
             x,y are the current contents of X- and Y-
             registers, respectively.
             S+ (sigma +) performs the addition (see 22)
             Decrease the indirect storage register index
             to the value of the last entry in LBL0
12  DSZ     Decrease the indirect storage register index
13  GSB2    Call the LBL2
14  RTN     Return to LBL1. Calculation is completed.
15  LBL2    Statistical Summation Routine
-----

```

```

16 RCL 1 Recall last -LT50
17 RCL 9 Recall K2
18 e*x Calculate -K2*LT50
20 DSZ 1 Calculate EXP(-K2*LT50). THIS IS "Y" FOR
21 RCL 1 THE SUBSEQUENT REGRESSION(the dependent variable)
Decrease indirect storage register index
Recall CW corresponding to the current
22 S + LT50. THIS IS "X" FOR THE SUBSEQUENT
REGRESSION(the independent variable)
(sigma +) Perform statistical summation
on the contents of X- and Y- registers
23 DSZ 0 (CW and EXP(-K2*LT50), respectively)
24 RCL 0 Decrease indirect storage register index
25 RCL 0 Recall the index into the X-register
Recall the "control value" 16 into the
X-register. This operation lifts the stack,
so that the indirect storage register index
is now in the Y-register
26 - Calculate the difference;
Indirect storage register index - 16,
place it into the X-register
27 x>0 If the difference is positive, not all data
have been used as yet. EXECUTE STEP 28
If the difference is 0, all data have been
used. BYPASS STEP 28
28 GTO 2 Start again LBL2
29 GSB 3 Call LBL3
30 RTN LBL2 is completed
WITH THE TEST DATA:

```

LT50	CW
0.7	30
1.4	5
3.3	0.5
4.2	0.25

K2=0.4
ON COMPLETION OF THE STATISTICAL SUMMATIONS
(that is just before going to LBL3),
the contents of the statistical registers
are:
R.0 4
R.1 6.2333
R.2 20.0411
R.3 1.7805
R.4 1.0036
R.5 1.4192
THE REGRESSION EQUATION IS
y = B*x + A
WHERE
 $B = \frac{[S(xy) - S(x)S(y)/n]}{[S(x^2) - (S(x))^2/n]}$
 $A = \frac{[S(x^2)S(y) - S(x)S(xy)]}{n[S(x^2) - (S(x))^2/n]}$
AND THE CORRELATION COEFFICIENT r =
 $B \sqrt{\frac{[S(x^2) - (S(x))^2/n]}{[S(y^2) - (S(y))^2/n]}}$

```

31 LBL3 Regression routine
=====
RCL 1 S(x)
x^2 <S(x)>^2
RCL 0 n
/ <S(x)>^2/n
CHS -(S(x))^2/n
RCL 2 S(x^2)
+ S(x^2) - (S(x))^2/n
STO 1 Denominator of A and B, store in R1
RCL 3 S(y)
x^2 <S(y)>^2
RCL 0 n
/ <S(y)>^2/n
CHS -(S(y))^2/n
RCL 4 S(y^2)
+ S(y^2) - (S(y))^2/n
STO 2 Needed for r, store in R2
RCL 1 S(x)
RCL 3 S(y)
* S(x)*S(y)
RCL 0 n
/ S(x)*S(y)/n
CHS -S(x)*S(y)/n
RCL 5 S(x*y)
+ S(x*y) - S(x)*S(y)/n
STO 3 Numerator of B, store in R3
RCL 3 S(y)
RCL 2 S(x^2)
* S(y)*S(x^2)
RCL 1 S(x)
RCL 5 S(x*y)
* S(x)*S(x*y)
- S(y)*S(x^2) - S(x)*S(x*y)
RCL 0 n
/ [S(y)*S(x^2) - S(x)*S(x*y)]/n
RCL 1 S(x^2) - (S(x))^2/n
/ Divide the contents of R3 by the contents
of the X-register and store the result
in R3; R3 now contains B
68 / [S(y)*S(x^2) - S(x)*S(x*y)]/
/n * [S(x^2) - (S(x))^2/n]
69 STO 4 THIS IS A
store it in R4

```

```

70      RCL 2      S(y^2)-(S(y))^2/n
71      STO 7.1    Divide the contents of R1 by the contents
              of the X-register and store the result
              in R1. R1 now contains
              [(S(x^2)-(S(x))^2/n)/[S(y^2)-(S(y))^2/n]]
72      RCL 1      recall it into the R1 register
73      #square root symbol square root on X-register
74      RCL 3      B
75      *          X-register now contains the correlation
              coefficient r
76      RTN       Regression calculations are completed
77      LBL9      Evaluation routine

```

=====
CALCULATOR STATUS:

R9 = K2
R4 = A
R3 = B
X-REGISTER = CW

```

78      1/x       1/CW
79      RCL 3     B
80      *        B/CW
81      RCL 4     A
82      +        A+B/CW
83      ln       ln(A+B/CW)
84      RCL 9     K2
85      /        ln(A+B/CW)/K2
86      CHS      X-register now contains calculated LT50
87      RTN      Calculation is completed

```

First step in the calculation is to estimate K2.
A good K2 value yields a correlation coefficient <-0.9 and
the absolute value of B is usually at maximum.

KEY STROKES:

16 STO 0; STO 8; K2 STO 9 [initialization]
Key in LT50; ENTER; Key in CW; GSB 0 [repeat with each LT50,CW pair]
GSB1 [regression is calculated, correlation coefficient is
displayed, A is stored in R4, B in R3.]

TO REPEAT THE CALCULATION WITH A NEW VALUE OF K2:

Key in the new value of K2
STO 9;
Key in N+16 (N = number of data pairs times 2)
STO 0
GSB1

TO CALCULATE LT50 FROM CW:

Key in K2;
STO 9
Key in A;
STO 4
Key in B;
STO 3

[The above needed only when other than the current K2,A, and B
values are used]

GSB 9

LBL3 is a general regression calculation and may be used
for other purposes as well. Just make certain that the
statistical registers contain the desired values and depress
GSB3
