Unemployment Insurance Evaluation Series

Human Resources Development Canada (HRDC), in its policies and programs, is committed to assisting all Canadians in their efforts to live contributing and rewarding lives and to promote a fair and safe workplace, a competitive labour market with equitable access to work, and a strong learning culture.

To ensure that public money is well spent in pursuit of this mission, HRDC rigorously evaluates the extent to which its programs are achieving their objectives. To do this, the Department systematically collects information to evaluate the continuing rationale, net impacts and effects, and alternatives for publicly-funded activities. Such knowledge provides a basis for measuring performance and the retrospective lessons learned for strategic policy and planning purposes.

As part of this program of evaluative research, the Department has developed a major series of studies contributing to an overall evaluation of UI Regular Benefits. These studies involved the best available subject-matter experts from seven Canadian universities, the private sector and Departmental evaluation staff. Although each study represented a stand alone analysis examining specific UI topics, they are all rooted in a common analytical framework. The collective wisdom provides the single most important source of evaluation research on unemployment insurance ever undertaken in Canada and constitutes a major reference.

The Unemployment Insurance Evaluation Series makes the findings of these studies available to inform public discussion on an important part of Canada's social security system.

Abstract

Unemployment Insurance (UI) and social assistance (SA) are the two principal components of the income security system for Canada's working age population. In the 1992–93 fiscal year, the combined expenditures for the two programs accounted for more than \$48 billion. In 1992, 1.4 million individuals received UI and approximately 2.7 million received social assistance or welfare.

However, in spite of the size of these programs and recent concerns about their fiscal sustainability, there is very little work, to date, directly examining the interaction between the UI and welfare programs.

The principal objective of this paper is to present descriptive information on the population of UI and welfare recipients in five Canadian provinces. The information is based on data derived from the administration of the welfare and UI programs in the provinces of British Columbia, New Brunswick, Newfoundland, Prince Edward Island and Alberta.

By matching case records for individuals who participate in both programs it is possible to compare the characteristics and experiences of the subset of individuals who use both programs to the larger population of participants of each program separately. In this way it is possible to determine if the UI and welfare programs serve essentially separate, distinct populations or whether they serve a similar set of people.

After presenting basic descriptive information on the overlap in the clientele of the UI and SA programs, the study analyses the impact of SA participation on the duration of UI spells. Due to the limited nature of the SA data in the other provinces, this analysis focusses on New Brunswick and British Columbia.

We find that a large proportion of welfare recipients have some attachment to the workforce and that there is a large overlap in the clientele of UI and SA. There is also evidence of an upward trend over the 1986–92 period in the extent to which the programs serve a common group of participants. Welfare spell durations had a distinct bimodal distribution, with UI-SA interaction concentrated among short welfare spells. SA use was found to be associated with substantially longer UI spells in New Brunswick but not British Columbia.

The evidence suggests that the individuals who participate in both the UI and SA programs may differ in their labour market opportunities and behaviour from those who participate in only one program. However further research is required to better understand the source of these differences.

Introduction

There is very little work directly examining the interaction between the UI and welfare programs.

Unemployment Insurance (UI) and social assistance (SA), also referred to as income assistance or welfare, are the two most important income security programs for Canada's working age population. In the 1992–93 fiscal year, the combined expenditures for the two programs accounted for more than \$48 billion, approximately \$27 billion being the combined federal, provincial and municipal spending on welfare programs and approximately \$21 billion being the expenditure on UI, making these programs the two largest (in terms of expenditure) components of the Canadian social security system (Human Resources Development Canada, 1994a).

Both are also large in terms of the number of individuals and families who interact with the programs. The average number of beneficiaries of the programs during 1992 was 1.4 million for UI and approximately 2.7 million for social assistance or welfare. Over recent years there has been a growing concern for the fiscal sustainability and the efficacy of the income security programs (Human Resources Development Canada, 1994b; OECD, 1994). As a consequence, the federal and several provincial governments have recently been considering major reforms to the income security system.

In considering alternate reform proposals it is important to first understand how individuals use and interact with the current programs. There is a substantial literature examining the use and behavioral effects of UI in Canada. Recent surveys of this literature are provided by Green and Riddell (1993), Corak (1994) and Gunderson and Riddell (1995), among others. Recently a number of researchers, such as Allen (1993), Bruce et. al. (1993), Charette and Meng (1994) and Barrett and Cragg (1995), have begun describing and analyzing how individuals and families interact with Canada's welfare programs.

However, to date, there is very little work directly examining the interaction between the UI and welfare programs. This is an important gap because there is a widespread perception that the two income security programs may increasingly overlap. Because there has been very little previous research on the interaction between UI and SA there is a lack of even basic information. A principal objective of this project is to provide some of this basic descriptive information.

There are several avenues through which the UI and welfare programs may interact. Firstly, welfare is the income security program of last resort. Individuals and families in need, and who are ineligible for benefits under other programs, may turn to welfare for financial assistance. Therefore changes to the UI program that restrict eligibility, or decrease benefit durations, may have the consequence of shifting some individuals onto welfare.

Additionally, changes over time in the economy and the labour market may have contributed to welfare becoming a more frequent source of income support for segments of the workforce, including those who in the past may have relied solely on UI for this purpose. For instance, real wages have been stagnant since the late 1970s and the real wages of younger and less educated workers have declined. Further, the incidence of unemployment has increased, especially among young and less educated workers, and the amount of long term unemployment has risen.

These developments may contribute to individuals, particularly recent labour market entrants and those with limited skills and earnings opportunities, relying on UI and welfare more than previously. These changes in labour market conditions may also mean that the two programs are increasingly serving the same populations.

Administrative practices are another source of interaction between the two programs. For example, in the late 1980s significant backlogs developed in the processing of UI claims. The average time for the processing of a claim increased to more than 2 weeks, the waiting period before benefits may be received on a claim. These processing delays mean that eligible claimants may go without income for several weeks. Because of this hardship, individuals may turn to welfare for assistance while their UI claim is being processed. In the case of British Columbia, Bruce et. al. (1993) have documented the dramatic increase in the “UI pending” welfare caseload which resulted from these administrative features of the UI program.

Another source of interaction between the two programs is the practice of some provincial governments or their agencies of designing “job creation” programs so that social assistance recipients (or those who might otherwise become welfare recipients) will qualify for UI, thus shifting the cost of their income support from the provincially cost-shared social assistance program to the federal UI program. As this example points out, the two programs may interact even in situations where individuals are not observed to participate in both programs within a limited period of time.

The principal objective of this paper is to present descriptive information on the population of UI and welfare recipients in five Canadian provinces. The information is based on data derived from the administration of the welfare and UI programs in the provinces of British Columbia, New Brunswick, Newfoundland, Prince Edward Island and Alberta. The UI program is administered federally while the SA programs are administered provincially. Consequently, although the UI data is consistent across provinces, the information contained in the welfare data files varies across provinces.

The time period covered by the welfare data files also varies across the provinces. As a result, the research summarized in this report covers the interaction of UI and SA in British Columbia and New Brunswick for the years 1986–1992, Newfoundland for 1990–1992, and Prince Edward Island and Alberta for 1991–1992. Because of the limited time period covered by the available data, it is difficult to disentangle longer term trends relating to UI and SA, and their interaction, from the impacts of the 1990–1992 recession. In the cases of Newfoundland, Prince Edward Island and Alberta, separating underlying trends from cyclical factors cannot even be attempted because the administrative data are available only for the period which coincides with the 1990–92 downturn.

By matching case records for individuals who participate in both programs it is possible to compare the characteristics and experiences of the subset of individuals who use both programs to the larger population of participants of each program separately. In this way it is possible to determine if the UI and welfare programs serve essentially separate, distinct populations or whether they serve a similar set of people. To the extent that the two populations of beneficiaries overlap, the characteristics of the people who rely on both programs may be determined along

with the typical time pattern of their interaction with the programs. By using the longitudinal information in the administrative data it is also possible to discern whether the time pattern of the interaction of the programs has changed over time.

After presenting basic descriptive information on the overlap in the clientele of the UI and SA programs, the study analyses the impact of SA participation on the duration of UI spells. Specifically, we test the hypothesis that the duration of UI spells differs according to the welfare history of the claimant. This analysis is limited to the provinces of British Columbia and New Brunswick; the data period for the other three provinces is too short for the analysis to be feasible.

The paper proceeds by briefly outlining the objectives of the UI and welfare programs. In section 2 the data used in the study are described in more detail. In section 3 descriptive statistics on the population of recipients of both programs are presented. Particular attention is paid to the characteristics of individuals who interact with both programs. Section 4 reports our analysis of the relationship between welfare history and the duration of UI spells in the provinces of British Columbia and New Brunswick. The final section summarizes the main conclusions of the study.

... the UI program has increasingly become an income support program in addition to a social insurance program.

1. The Unemployment Insurance Act and the Canada Assistance Plan

Unemployment Insurance

In many respects the UI and welfare programs are fundamentally different, for they were originally designed to serve very different purposes. The UI program was established in 1940 and although the program has substantially changed since then, the program's primary objective remains the provision of insurance to labour market participants for the temporary loss of income during periods of unemployment. With the major reforms in 1971, the goals of the program expanded to include special benefits for absences from work due to sickness, temporary disability and the birth or adoption of a child. By 1971 the UI program covered over 95 percent of all paid workers. During the past two decades in particular, the UI program has increasingly become an income support program in addition to a social insurance program (Gunderson and Riddell, 1995).

However the UI program is not a universal income support program. It specifically excludes individuals who do not have some labour force attachment in the form of recent employment, who are self employed or who have exhausted their benefit entitlement. Furthermore, benefits paid under the program are based mainly on previous earnings rather than need.

Despite the changes to the program since the late 1970s, which generally made the program more restrictive or less generous, UI expenditures and the number of beneficiaries have grown substantially since 1970. Real UI benefit expenditures (measured in 1992 dollars) increased six-fold from less than \$3 billion in 1970 to \$19 billion in 1992 (OECD, 1994). The average number of weekly beneficiaries grew from approximately 0.7 million in 1976 to 1.4 million in 1991–92. The severe recessions in 1981–82 and 1990–92 were associated with sharp increases in the number of beneficiaries and expenditure; however, there were not equivalent declines in the intervening years of economic growth.

Social Assistance

The present welfare programs in Canada were established under the Canada Assistance Plan (CAP) of 1966. The objective of Canadian welfare programs is to provide financial assistance to all individuals and families in need, irrespective of the causes of the hardship. Unlike UI, welfare is a universal program covering all people in need. Eligibility for the receipt of welfare is not tied to previous employment, benefits are not related to prior earnings nor is there a limit on the length of time a person may receive benefits.

Under CAP the federal government sets broad guidelines on the eligibility criteria and the implementation of the “needs test” by which eligibility is assessed and shares equally with the provinces in the costs of those programs.¹ The provinces are responsible for administering the programs and have substantial discretion in determining the rules and the benefit structure in their jurisdiction. Consequently there is considerable diversity in the welfare programs across the provinces and territories of Canada.

¹ However in 1990 the federal government placed an upper limit of total CAP payments to the three “have” provinces of Ontario, Alberta and British Columbia.

A common feature of the provincial welfare programs is the central role of the needs test. To qualify for welfare a household undergoes a budgetary assessment, which takes into account both the household's basic needs and the resources available to meet them. A deficit between assessed needs and available resources qualifies the household for welfare. The amount of assistance depends on the household's budgetary deficit, employability status, and family status and size, subject to a maximum amount.

The welfare programs in Canada have witnessed a similar trend of dramatically increasing caseloads and real resource costs over recent decades. Total real welfare expenditures have increased from \$1.7 billion in 1958–59 to \$17.6 billion in 1990–91. Since the introduction of CAP in 1966 expenditures have increased almost three-fold. In terms of direct assistance payments, real expenditures increased by 250 percent from 1970–1990. The number of welfare recipients in Canada grew from 1.2 million (or 6 percent of the population) in 1968 to approximately 2.7 million (over 10 percent of the population) in 1992. As was the case for UI, the caseload and real cost of the welfare programs experienced large increases following the recessions of 1980–81 and 1990–92 without a significant decline in the intervening years of economic and employment growth.

2. Data and Methods

The data on welfare use are based on the case records of a random sample of individuals with a history of welfare receipt in the five provinces between 1986 and 1993, though the time period varies from province to province.

The data used in the study are a random sample of case records derived from the administration of UI and the provincial welfare programs. The UI sample is drawn from the Status Vector File of Human Resources Development Canada's UI Longitudinal File. Each record in the sample corresponds to a UI claim initiated by an individual residing in the provinces under study. The file contains information on all the UI claims for a random 10 percent of people with a UI history, in each of the provinces, sometime during the 1986–1992 period. The random sample is generated by drawing the claim records for all individuals with a Social Insurance Number (SIN) ending with the numeral 5. (To preserve confidentiality, the SIN is masked so it cannot be observed by the researcher.)

Information on each UI claim that is used in this study includes the date of benefit period commencement and the duration of the claim period, the total number of weeks in which benefits were paid on the claim, the number of weeks of disqualification or disentitlement, the benefit rate, the number of weeks of insured employment and the sum of insured earnings. There is further information on whether the claim was associated with the developmental use of UI funds (including their use for training, work-sharing and job creation programs) and whether the claimant participated in government sponsored training programs, such as the Adult Occupational Training Act (AOTA) and Canada Jobs Strategy (CJS).

Additionally, the claim type is identified (such as regular, or unemployment related UI; sickness; fishing; maternity/parental; retirement; AOTA).² The reason for claim termination is provided and grouped into 5 categories (not terminated, lapsed, exhausted, externally terminated (such as due to disqualification) and terminated at 52 weeks (which is when the benefit period expires)). There is detailed information on the occupation and industry of most recent employment. The demographic information available on the claimant is limited to sex and age.

The data on welfare use are based on the case records of a random sample of individuals with a history of welfare receipt in the five provinces between 1986 and 1993, though the time period varies from province to province. Analogous to the UI file, the random sample is obtained by drawing the records for all individuals with a SIN ending in 5. The raw data consist of a record for each month an individual received welfare. From this file, welfare spells (consecutive months of welfare receipt) were constructed.

For each welfare spell there is information on the start date of the spell and spell duration (in months) and whether it is right censored,³ plus the sex and age of the recipient. Additional variables common to all the welfare files are family type and employability status. Furthermore, marital status, educational attainment, employment status, UI status and occupation are recorded in several of the provincial welfare files.

² Records with claim type of "No Trailers Present" were dropped from the analysis. For claims of this type no UI benefits are paid, most likely due to the ineligibility of the claimant as indicated by the very low number of weeks of insured employment.

³ Right censored spells are those that were still in progress at the end of the data period; hence their ending date and the duration of the completed spell is not observed.

The employability status of an individual or family is important in determining their eligibility for assistance and the level of benefits they may receive. The definition of an “employable” person varies across provinces; however, the criteria generally relate to whether the individual, or a family member, has a disability or whether the individual is a single parent.⁴ For example, in British Columbia, in 1992, a person was classified as employable if they were not:

- 65 years of age or older;
- temporarily or permanently unable to work due to medical reasons;
- a single parent with one dependent child under six months of age or two or more dependent children under 12 years of age; or
- a single parent required to stay at home to care for a disabled child.

The definition of employability with respect to single parents with young children was most stringent in British Columbia and Alberta. In Alberta, prior to 1991, a lone parent with one child was considered employable if the child was over 4 months of age. In February, 1991 Alberta increased this to two years of age, which corresponds to the age adopted by most other provinces. Newfoundland is exceptional in treating a person as “unemployable” if they received SA benefits for reasons other than unemployment.

A key advantage of these administrative data is that they provide an accurate history of an individual’s use of UI and welfare over an extended period of time. This is very important given the limitations of alternative data sources, which are the Survey of Consumer Finances (SCF) and the Labour Market Activity Surveys (LMAS). Both the SCF and the LMAS contain information on UI and welfare receipt; however, it has been found that both surveys underreport government transfer income, which is predominantly UI and welfare, by up to 30 percent. Furthermore the SCF is purely cross-sectional and so cannot be used to analyse the time pattern of individual’s interaction with the two programs. Although the LMAS contains longitudinal information, the longest panel covers only 3 years, 1988–90, which severely constrains an analysis of the dynamics of program participation.

An additional advantage of the administrative data includes the fine level of time aggregation (weekly for UI and monthly for welfare) corresponding to the time scale by which the programs are administered. The data also provide detailed program-related information on the individual and their application for benefits.

The limitations of the data, like other administrative data, include the lack of information on individuals when they are not participating in the program plus the limited amount of demographic information they contain, especially in relation to the UI file. An additional limitation of these data derives from the fact the UI program is individual based whereas welfare is family based. In general, if an individual is a member of a family that received welfare and that person was not the principal claimant then he/she will not be observed in the welfare file.⁵

4 See National Council on Welfare (1987) for definitions of “employable” in each province. More recent information is available from the respective departments or ministries of social services.

5 The exception is the welfare file for Prince Edward Island, which contains records for the household head and spouse if both have SINS ending in “5”.

Therefore it is not possible to identify the welfare histories of every individual in the UI file. Finally, the very short time period over which the data for Newfoundland, Prince Edward Island and Alberta are available implies that we are unable to analyse the dynamics of social assistance and UI participation and changes over time in these provinces.

The separate UI and welfare files are matched using individuals' SINs. With the matched sample, three exercises are performed:

- (a) Descriptive statistics on the population of individuals who began a spell of welfare in specific calendar years are generated. Welfare recipients are then grouped according to whether they had a UI claim open during the same calendar year, and summary statistics on the "Non-UI history" and "UI history" subgroups are reported. The results are then compared across years to discern changes in the size and composition of the welfare population, and in the pattern of welfare use. Note that the sample is based on individual recipients⁶ and sample division is according to a UI claim being open, but not necessarily being initiated, in the same calendar year as the welfare spell began.
- (b) Descriptive statistics on the UI claims initiated in specific years are produced. Like the welfare sample, which is based on cases of actual SA receipt, the analysis of UI claims is limited to those claims where UI benefits were actually paid. The set of UI claims is then divided into three groups according to the following hierarchy:
 - UI claims where upon the termination of the claim, the individual immediately (within one month) began a spell of welfare receipt;
 - UI claims where the claimant had a welfare spell overlapping with the UI claim period; and
 - those claims where there was no welfare receipt by the same person during or immediately after the UI claim.

The groups are referred to as the *Subsequent UI-welfare*, *Concurrent UI-welfare* and *UI only* beneficiaries, respectively.⁷

The purpose of this sample division is to firstly distinguish the set of claimants who only use UI from those that use welfare and UI, and then to distinguish among the latter those who tend to move onto welfare following a period of UI receipt. This *subsequent UI-welfare* group is of particular concern to policy makers in that it includes individuals who appear to face the greatest difficulties obtaining or retaining employment. In contrast, the *concurrent UI-welfare* group includes "UI pending" welfare recipients who receive welfare benefits while their UI claim is being processed, and whose receipt of social assistance is thus administrative rather than behavioral in nature.

⁶ Therefore, if an individual began two or more welfare spells in a given year, the total duration of all spells combined is calculated though the individual's demographic characteristics at the commencement of the first spell are retained.

⁷ The majority of individuals in the subsequent UI-welfare group also had a separate, prior spell of welfare that overlapped with the initial weeks of the UI claim and hence this group may also be labelled UI-Welfare cyclers.

Overall, exercises (a) and (b) should reveal to what extent the UI and welfare programs serve different populations and, as far as the populations do overlap, the characteristics of the those that do interact with both programs within a limited period of time.

- (c) The regular UI claims by males in British Columbia and New Brunswick are matched against the welfare files to determine if the claimant received welfare during a 24 month time period beginning 27 months prior to the commencement of the claim. The UI claims are separated into two groups; claimants with and without a recent history of welfare participation. The samples are then analyzed in a hazard function framework to test whether the receipt of welfare is associated with longer subsequent UI spells.

The criteria used to measure UI-SA interaction in (a), (b) and (c) are necessarily arbitrary. We have chosen to examine the extent of overlapping participation in the two programs within limited periods of time. Thus, for example, welfare recipients who were or are UI beneficiaries in a previous or subsequent year would not be classified in the UI history group. Similarly, those who take more than one month to move onto welfare following the completion of a UI spell would be classified as *UI only* according to (b). Because we restrict the analysis to participation in both programs within limited periods of time, our investigation may understate the magnitude of UI-SA interaction and will be useful as a lower bound measure of the extent to which the two programs serve an overlapping clientele.

A large proportion of the welfare spells which commence in a given year are experienced by single men and women with no dependants.

3. Features of UI-SA Interaction

We have extracted a large amount of information from the UI and SA administrative files and report this information in a sequence of tables which can be found in Appendix A. The tables are organized as follows. First, we use the SA data to describe the characteristics of welfare recipients in each of the five provinces. Information is provided on the total population (some of which is provided in other publicly available sources) as well as for social assistance recipients (SARs) with and without a UI history (information which is generally not publicly available). Second, for the two provinces for which there is a sufficiently long time period (New Brunswick and British Columbia) we examine the duration of welfare spells, and report summary statistics for the total population as well as for those with and without a UI history. Third, we use the UI administrative data to describe the characteristics of UI recipients, and provide this information for the total population as well as breakdowns for the UI only, UI-concurrent welfare and UI-subsequent welfare groups.

Characteristics of Welfare Recipients

Summary statistics on the characteristics of SARs who began a welfare spell in the year noted are reported in Tables A.1–A.3 (for British Columbia), A.4–A.6 (New Brunswick), A.7–A.9 (Newfoundland), A.10–A.11 (Prince Edward Island) and A.12–A.13 (Alberta). Information is provided for the following years, corresponding to the data which is available for each province: 1986, 1989 and 1992 for British Columbia and New Brunswick; 1990, 1991 and 1992 for Newfoundland; and 1991 and 1992 for Prince Edward Island and Alberta.

The content of the tables varies somewhat according to the information available in each province's administrative data. For each province, we report basic demographic information, family type, employability status, and both the number and average duration of welfare spells. Additional information provided for some provinces includes marital status, education, occupation, employment status and disability status, as well as the administrative status of the claim. All of this information is provided for the total SA population in the year in question and separately for those with and without a UI spell in that year.

Not surprisingly, there are both similarities and differences in the nature of welfare recipients in these jurisdictions. In all provinces, the majority of principal claimants are male and the average age ranges from 30 to 35. The average number of dependent children varies substantially across provinces, from about 0.3 in British Columbia to 0.8 in Prince Edward Island and Newfoundland. The average duration of SA spells also varies across provinces, in 1992 from a low of 5.1 months in Alberta to a high of 9.6 months in New Brunswick.

A large proportion of the welfare spells which commence in a given year are experienced by single men and women with no dependants. For example, in 1992 this proportion ranged from approximately 54 percent in Alberta to 71 percent in British Columbia. Single parents accounted for approximately 15 to 20 percent of all welfare spells which commenced in 1992 in the five provinces. A majority of the people who receive welfare in a given year are neither ill nor disabled but are

“employable”;⁸ during 1992 these accounted for between 63 percent of SARs in New Brunswick to 89 percent of SARs in British Columbia. Although this observation has been made by others, it is worth emphasizing because it contrasts with what continues to be a common perception that welfare is predominantly used by single parents or individuals with disabilities.

Information on educational attainment is provided in the data files for New Brunswick, Newfoundland and Prince Edward Island. For these provinces, welfare recipients, on average, have a low level of formal education. For example, in 1992 from 44 percent to 64 percent of welfare recipients in these provinces had completed schooling of grade 10 or less.

By matching the welfare and UI files we find that a large proportion of welfare recipients also participated in the UI program in the same calendar year. For example, in 1992 the proportion of welfare recipients who also received UI benefits ranged from 32 percent in Alberta, 34 percent in New Brunswick and British Columbia, to 53 percent in Newfoundland and 55 percent in Prince Edward Island. In addition, some of those in the non-UI history group are receiving welfare while awaiting UI benefits, as illustrated for the case of British Columbia in Table A.1. These results suggest that, in recent years, there is a large overlap in the clientele of UI and SA.

There are a number of distinct differences between the UI history and non-UI history groups. In all provinces SARs with a UI history are more likely to be male and “employable” and to have much shorter welfare spell durations. However, in other respects (average age, number of children, family status) there is not a common pattern of differences across provinces between these two groups.

In comparing the descriptive statistics for the welfare spells over time a number of common trends are evident. The strongest, and most obvious, is the dramatic growth in the sample sizes and hence program caseloads. In British Columbia and New Brunswick from 1986 to 1989, a period of relatively strong economic and employment growth, the number of cases grew by 14.5 percent and 3 percent, respectively (see Tables A.1 and A.2 for British Columbia and A.4 and A.5 for New Brunswick). Following the onset of the recession in 1990, the caseloads grew from 1989 to 1992 by a further 62 percent and 39 percent, respectively (compare Tables A.2 and A.3 for British Columbia and similarly for New Brunswick). For the other provinces it is only possible to examine year to year changes in the caseloads after 1990 (again, compare across years for each province); from 1990 to 1992 the number of cases grew by 14 percent in Newfoundland, and from 1991 to 1992 by 17 percent in Alberta and a massive 140 percent in Prince Edward Island.

Although the recession of the early 1990s was an important factor contributing to the growth in welfare recipiency, the upward trend in welfare caseloads during the late 1980s in New Brunswick and, especially, British Columbia cannot be attributed to such cyclical factors. This evidence, together with the observation made

8 As discussed previously, the definition of “employable” varies across provinces and in some provinces has changed over time. Thus some of the differences across provinces in the proportion of SARs who are deemed to be “employable” may be due to these different definitions rather than to differences in the characteristics of the SARs population in each province.

by others that the recessions of 1974–75 and 1981–82 tended to have a ratcheting effect on aggregate caseloads,⁹ suggests that underlying structural factors were contributing to a rising proportion of the population being on welfare prior to the 1990s.

Coincident with the growth in the size of the welfare population was a change in composition. Because only New Brunswick and British Columbia are observed for more than 3 years, we focus on the compositional changes in these provinces. In many respects the story is similar in both jurisdictions. Over the 1986–92 period there were significant increases in the proportions of the SA population who are single men and women without dependants, employable, and who also experienced a UI spell in the same year. At the same time, the proportion of single parents on welfare declined and the average duration of welfare spells fell dramatically — in British Columbia from over 14 months in 1986 to 6.7 months in 1992 and in New Brunswick from 19.2 months in 1986 to 9.6 months in 1992.¹⁰

Although the recession of 1990–92 and the changes made to the UI program in the early 1990s are often cited as factors contributing to these changes in the nature of the SA caseload, it is clear from Tables A.1–A.3 and A.4–A.6 that additional factors must be at work. Indeed, most of the changes noted above — the increasing overlap in the clientele of the SA and UI programs, as measured by the fraction of SA recipients receiving UI in the same year, the rise in the number of single men and women on welfare, the increasing proportion of the SA population deemed to be employable, and the decline in the average duration of SA spells — occurred to a equally large or even greater degree between 1986 and 1989, a period of strong employment growth, than between 1989 and 1992.

Duration of Welfare Spells

Since the data files for New Brunswick and British Columbia cover a longer period of time, we are able to analyse the length of welfare spells in these two provinces. These results are reported in Tables A.14–A.16 for British Columbia and A.17–A.19 for New Brunswick. For each of the years 1986, 1989 and 1992 the tables show summary statistics on the SA population broken down by the following spell durations: 1–3 months, 4–6 months, 7–9 months, 10–12 months, 13–18 months and 19 months and over. Data for all durations are also reported for comparisons with the population as a whole.

A number of conclusions are evident from these tables. Perhaps the most striking feature is that in both provinces and for all three years, there are both large numbers of short and of long welfare spells. The majority of those who receive welfare in a given year tend to remain on the program for six months or less (and most of these have spells of 1–3 months); however, there is also a substantial number who remain on the program for more than 18 months. The distributions of welfare spells have a distinct bimodal character. SARs with short spells are more likely to

⁹ That is, the increase in the caseloads following the onset of the recessions were not mirrored by a similar decline during the ensuing recovery: see OECD (1994) and Brown (1995).

¹⁰ Because there are large differences in the duration of welfare spells according to such factors as age, family type and employability status (see Barrett and Cragg, 1995, for evidence from the province of British Columbia), changes in the composition of the SARs population can be expected to result in changes in average spell duration.

be male, young, single or a member of a two parent family, and employable. The New Brunswick data also indicate that individuals with higher levels of completed education tend to have significantly shorter welfare spells. Those with long spells are more likely to be single parents and individuals who were either ill or disabled and unable to work. Although not shown in the tables, further examination of the spell duration data reveals that a small subset of these groups remain on the program for several consecutive years, and therefore account for a greater proportion of the population in receipt of welfare at a point in time and of total welfare expenditures over a period of time.

In both New Brunswick and British Columbia, a large proportion of the short welfare spells involve individuals who also received UI in the same year. Indeed, in both provinces more than half of the 1–3 month spells are experienced by such individuals. Thus examining the welfare data alone could result in an inappropriate characterization of these individuals' labour market behaviour and opportunities. Although they are able to exit from welfare quickly, their total reliance on income support is greater than suggested by the welfare case history alone.

The proportion of SARs with a UI history declines with spell duration, but nonetheless remains substantial even for those who experience very long spells. In British Columbia, over 20 percent of welfare recipients with spells exceeding 18 months also had a UI claim open during each of the years 1986, 1989 and 1992. The comparable figures are somewhat lower in New Brunswick, and vary from 13 to 22 percent depending on the year. Thus in both provinces, UI-SA interaction is substantial across the distribution of welfare spell durations, although more concentrated among the shorter spells.

UI Beneficiaries

A further dimension of the UI-SA interaction is revealed by examining UI spells and dividing claimants according to their receipt of welfare. Summary statistics are reported in Tables A.20–A.22 (for British Columbia), A.23–A.25 (New Brunswick), A.26–A.28 (Newfoundland), A.29–A.30 (Prince Edward Island) and A.31–A.32 (Alberta). As was the case previously, we report information for the years 1986, 1989 and 1992 for British Columbia and New Brunswick, 1990, 1991 and 1992 for Newfoundland, and 1991 and 1992 for Prince Edward Island and Alberta. The UI data contain only limited demographic data (age and gender) but do provide detailed information on the UI claim as well as information on occupation and industry of last employment.

The descriptive statistics for the samples of UI spells in a given year show that the average claim period is substantially longer than the duration of actual benefit payments (even when the waiting period is taken into account). For example, in 1992 the average claim period varied from 44.9 weeks in British Columbia to 46.8 in New Brunswick, whereas the average number of weeks of benefit payments were 24.3 and 28.6, respectively. The average number of weeks of insured employment supporting the UI claims in 1992 varied from 22.3 in Newfoundland to 39 in Alberta.

The vast majority of the UI claims are for regular, or unemployment related, benefits. Generally, the most common reasons for claim termination are due to claims lapsing, presumably because the claimant found employment, or because the

claim period (52 weeks) expired. However, as discussed below, the reasons for claim termination vary greatly across subgroups of claimants and over time with the business cycle.

As described in section 2, the UI spell samples are stratified into three groups, the *UI only* claimants, the *concurrent UI-welfare* claimants and the *subsequent UI-welfare* claimants. While most UI beneficiaries belong to the UI only group, a significant fraction are in one of the UI-welfare groups. For example, in 1992, approximately 15 percent of claimants in British Columbia, 13 percent in Alberta, 10 percent in Prince Edward Island and 7 percent in New Brunswick and Newfoundland, were in the combined welfare subgroups.

In general, claimants in the welfare subgroups of the UI populations have, on average, longer UI claim periods and weeks of benefit receipt but fewer weeks of insured employment. In addition, the insured earnings of members of the welfare subgroups are, on average, significantly lower than that for the population of UI beneficiaries as a whole. The UI-welfare subgroups also exhibit a higher incidence of benefit exhaustion. The findings suggest that individuals in the UI-welfare subgroups differ from other UI claimants in their labour market opportunities and behaviour.

In comparing the two UI-welfare subgroups, the concurrent user group generally accounts for a greater proportion of claimants. The subsequent UI-welfare users generally have, on average, more weeks in which benefits were paid though fewer weeks of insured employment. Moreover, the subsequent UI-welfare group has the lowest average insured earnings, and hence benefit levels, and the greatest incidence of UI benefit exhaustion. For this group, benefit exhaustion tends to be the most common reason for claim termination except in British Columbia where “benefits lapsed” tends to dominate. This difference may be the consequence of the more buoyant economic conditions in British Columbia than in the other provinces during this period.

A number of common changes over time were evident in these five provinces. There is much clearer evidence of cyclical sensitivity of the UI caseload than was the case for welfare. From 1986 to 1989, a period of strong economic and employment growth, the number of UI recipients changed by -4 percent and +9 percent in British Columbia and New Brunswick respectively. Following the onset of the recession in 1990, the number of UI claimants increased from 1989 to 1992 by 19 percent in British Columbia and 28.6 percent in New Brunswick. The number of claimants in Newfoundland increased by over 27 percent from 1990 to 1992; in Alberta and Prince Edward Island the increase from 1991 to 1992 was 7 percent and zero percent respectively. With the exception of Prince Edward Island, the number of UI claimants grew dramatically as the 1990–1992 recession progressed.

The experience of Prince Edward Island stands out as a special case. From 1991 to 1992 the aggregate UI caseload in Prince Edward Island remained static while the welfare caseload increased by 140 percent. Coinciding with the increase in the size of the welfare population were significant changes in composition; these included increases in the proportion of claimants who were employable and who were employed in seasonal jobs. At the same time, the average duration of welfare

spells declined, indicating that the welfare population were more mobile, exiting the program more quickly in 1992. Although the limited time period covered by the Prince Edward Island data precludes further analysis, the evidence suggests that many individuals who would normally rely on UI for income support shifted to welfare as the recession proceeded to take its toll on economic activity.

Further developments evident from the analysis of the UI samples include the substantial increase in the average length of the claim period, with little or no increase in the duration of benefit payments. With the progression of the 1990–1992 recession, there was a substantial increase in the incidence of benefit exhaustion in all five provinces. The increase in average claim durations but little (or negative) change in the duration of benefit payments, and the increase in incidence of benefit exhaustion were more pronounced among the UI-welfare groups, especially the subsequent UI-welfare group.

In the two provinces for which data are available over the 1986–92 period, there is evidence of a trend toward an increasing proportion of UI claimants to be classified in the UI-welfare subgroups. In British Columbia, the fraction of UI claimants who also interacted with the welfare program in a limited period of time increased from 6.6 percent in 1986 to 9.8 percent in 1989 to 15.1 percent in 1992. In New Brunswick, the comparable proportions were 4.7, 5.1 and 6.6 percent respectively. Thus examination of the UI data yields a similar conclusion to that obtained with the welfare data — an increased tendency for individuals to interact with both programs that was in place prior to the recession of the early 1990s.

4. Social Assistance and the Duration of UI Spells in British Columbia and New Brunswick

... when on welfare an individual is unable to accumulate work experience and their human capital may depreciate.

This section reports the findings of an analysis of one particular form of interaction between UI and welfare. Specifically, we test the hypothesis that the duration of UI benefit receipt differs according to the welfare history of the claimant.

There are several potential reasons why the receipt of welfare may influence an individual's subsequent use of UI. For example, by participating in the welfare program individuals may learn new information regarding the program administration, rules and benefit levels. These individuals would then be aware of the income that is available from welfare and which may be used to subsidise job search beyond UI exhaustion. Consequently, if unemployed and on UI, these individuals may not search as intensively, or may not lower their reservation wage as much as other UI claimants, as benefit exhaustion approaches.

In addition to the learning or informational effects of welfare participation on subsequent UI behaviour, the receipt of welfare may have a “scarring” effect on an individual's future labour market opportunities. To be on welfare individuals generally have to be unemployed. Consequently, when on welfare an individual is unable to accumulate work experience and their human capital may depreciate.¹¹ Furthermore, employers may use individuals' labour market histories in the screening of job applicants or in the determination of wage offers. Together, these factors introduce negative conditioning between an individual's participation in the welfare program and their future employment prospects and hence use of the UI program.

The objective is to test the hypothesis that the receipt of welfare in the recent past increases the average duration of UI spells. Given the nature of the data, it is not possible to identify the particular avenues (informational, human capital, screening etc.) through which this interaction may occur. In investigating this hypothesis it is important to control for the impact of UI benefit entitlement on the length of UI spells as well possible duration dependence effects of the UI program.¹²

Economic Model

The hypothesis of welfare receipt leading to longer subsequent UI spells can usefully be described in the context of a job search model. The negative impact of past welfare receipt on UI spell durations is posited to occur through learning about the welfare program; as stated above, this mechanism leading to the interaction between welfare and UI use is observationally equivalent to the human capital and employer screening impacts.

A popular way to model unemployment and UI spell durations is with dynamic job search models. Mortensen (1977) presents a dynamic search model where the

¹¹ Similar effects, of being unable to acquire work experience while human capital depreciates, are likely to occur when receiving UI.

¹² A worthwhile extension of the research presented here would be to control for unobserved individual characteristics (also known as unobserved heterogeneity). In this way, one could test whether any observed state dependence effects between UI and welfare are a product of the programs themselves or a reflection of unobserved individual characteristics (such as motivation, or for the data set at hand, education) which are correlated with longer expected UI spells.

hazard rate from unemployment and UI (the probability of exiting from unemployment and UI at week t , given that the UI spell has lasted t weeks) is proportional to:

$$s[1 - F(w)]$$

where s is search intensity, w is the individual's reservation wage and $F(.)$ is the cumulative distribution of wage offers. According to this model the hazard is increasing in search intensity because the arrival of job offers increases. Additionally, the hazard rate rises as the reservation wage declines because the likelihood of a job offer being acceptable increases. As an individual gets closer to benefit exhaustion s increases while w decreases, both implying that the hazard rises as exhaustion approaches.

After exhaustion, the individual may move onto welfare. Those with prior welfare receipt are potentially better informed about that program and thus face lower fixed costs of receiving welfare. Therefore, the prediction to be tested is that individuals with a recent welfare history tend to search less intensively and do not lower their reservation wage as much during the course of a UI spell as other UI claimants.

Data

The data used in this part of our analysis are similar to those used previously. The data on welfare participation are based on case records of a random sample of individuals with a history of welfare receipt in British Columbia and New Brunswick between 1986 and December, 1993. The UI data are restricted to the subset of regular UI claims initiated by men in British Columbia from January, 1988 to December, 1992 and in New Brunswick from April, 1988 to December, 1992. Claims that were for developmental purposes or where the claimant participated in government sponsored training programs were dropped from the sample. This step was taken because it is important to control for the potential duration of UI benefits in the empirical analysis, and this variable could not be accurately constructed for this special set of UI claims. Furthermore, the behaviour of claimants involved in training is potentially very different from the behaviour of UI claimants in general and merits a separate analysis.

The UI claims were matched with the welfare spell file using individual's masked SINS. The analysis is restricted to men because the matching of the UI and SA data is much more complete for this group. Each UI claim in the sample was matched against the welfare spell file to see if within a 24 month window, beginning 27 months prior to the commencement of the UI claim and ending 4 months prior to the UI claim, the individual had recently received welfare benefits. The time window with which to examine an individuals' welfare history was constructed so as to allow adequate time for a person to have been on welfare and in employment, in order to be eligible for UI. Additionally the time window ended three months prior to the UI claim commencement so to avoid sampling predominantly "UI pending" welfare spells.¹³ These welfare spells are a product of administrative practices of the UI system rather than of individual behaviour, and in terms of the

¹³ As noted previously, the UI pending welfare spells accounted for an important part of the increase in the British Columbia welfare caseload in the late 1980's (see also Bruce *et. al.*, 1993).

characteristics of such welfare spells, they are a special group which deserve a separate analysis.

The set of UI claims is separated into 2 groups, claimants with and without a recent welfare history. The primary variable examined in the analysis is the number of weeks that benefits were actually received on the UI claim. This definition of a UI spell may not correspond to consecutive weeks of UI receipt. While the UI claim is open, an individual may not receive any benefits in a given week due to full-time employment or disqualification. This definition of a UI spell — aggregate weeks of compensation paid on the UI claim — is very general.

An important variable in the analysis is the maximum potential duration of benefits payable on the UI claim. This variable was constructed using the number of weeks of insured employment in the qualifying period and the regional unemployment rate and the entitlement formula to calculate benefit entitlement as defined in the program rules. With this information, the number of weeks of benefit entitlement not utilised (or time until benefit exhaustion) was constructed. However UI claims that ended in exhaustion (15 and 22 percent of all claims in British Columbia and New Brunswick, respectively), were externally terminated or remained unterminated (7.8 and 11.8 percent in British Columbia and New Brunswick, respectively) were treated as right-censored.

Results

Summary statistics on the sample of UI claims for British Columbia are presented in Table 1. From the full sample of 42,946 UI claims, 37,519 (87 percent) were without a matched welfare spell while 5,427 (13 percent) did have a recent welfare history. The average duration of benefit entitlement is marginally greater for the non-welfare history sample at 45.9 weeks. The actual weeks of benefit receipt were approximately 2 weeks greater, at 28.5 weeks, for the welfare history sample. Correspondingly the average time until exhaustion is approximately 2.5 weeks less (at 16.8 weeks) for the welfare history sample. These summary statistics suggest that, in British Columbia, UI claimants who recently received welfare tended to have slightly longer UI spells and used up more of their benefit entitlement than other UI claimants.

Table 1
Summary Statistics on UI Claims in British Columbia, 1988–1992

Variable	All UI Claims	Non-Welfare Population	Welfare Population
Claim duration	39.121	38.868	40.869

Age	35.303	35.497	33.783
Right censored	0.338	0.324	0.456
Observations	22,706	20,138	2,568
Sample percent	100	89	11

Summary statistics on the sample of UI claims in New Brunswick are presented in Table 2. Of the sample of 22,706 UI claims, 20,138 (88.7 percent) were without a welfare history while 2,568 (11.3 percent) did have a recent history of welfare receipt. The average length of the benefit entitlement in New Brunswick was very similar to that for British Columbia at 45.8 weeks. In New Brunswick, the benefit entitlement was marginally less for the welfare history group; however, the actual weeks of benefit receipt were substantially greater (over 6 weeks greater at 33.2 weeks) for the welfare history group. As a result, the average time until exhaustion is 7 weeks less for the welfare history sample (at 11.6 weeks). These descriptive statistics show that UI claimants in New Brunswick who recently received welfare had substantially longer UI spells and utilised more of their entitlement, on average, than other UI claimants. Furthermore, the differences between the welfare and non-welfare history groups are much greater in New Brunswick than British Columbia.

There are a number of additional differences in the characteristics of the welfare and non-welfare history groups common to British Columbia and New Brunswick, as revealed in Tables 1 and 2. The number of weeks of insured employment and the benefit rate, which is based on prior earnings, are substantially less for the welfare subsample. Further, the welfare history group members tend to be younger (especially in British Columbia) and hence are likely to have less labour market experience. Lastly, the regional unemployment rate is slightly higher, on average, for the welfare history sample indicating they are in weaker local labour markets.

A more complete picture of the duration of UI spells is shown in Figures 1 and 2, which plot the empirical hazard rate function for the number of weeks of UI benefit receipt. The figures present separate plots for the non-welfare and welfare history groups for British Columbia and New Brunswick, respectively. Figure 1 shows that in British Columbia approximately 5 percent of claimants in both groups exit UI within the 2 week waiting period and hence do not receive any benefits. For spells from 1 to 36 weeks long, the conditional probability of individuals exiting the program is marginally higher for the non-welfare history group. Over the longest spells, from 37–50 weeks in length, the hazard rate is generally higher

Figure 1
British Columbia UI Benefit Receipt Empirical Hazard

Figure 2
New Brunswick UI Benefit Receipt Empirical Hazard

for the welfare history group. The major conclusion from Figure 1 is that, for both groups in British Columbia, the exit rate from UI increases slightly over short durations and then dramatically increases at spell lengths of 40 weeks or more.

Figure 2 shows that in New Brunswick approximately 3 percent of claimants in the non-welfare group exit UI within the 2 week waiting period. For the welfare group, only 1 percent of claims end within the waiting period. Further, as found for British Columbia, the hazard rate from UI, for both groups, increases gradually over short spell lengths and then increases more dramatically over the longest spells. There is a spike in the hazard rates for the two groups between 40 and 42 weeks which is explained by the fact that a large proportion of claimants exhaust their entitlement in this range. This underscores the need to control for initial entitlement when analyzing the exit rate from UI. The common pattern of an increasing exit rate from UI is consistent with the predictions of the search model discussed above, with the exit rate increasing as spell length increases and as benefit exhaustion approaches.

A major feature of Figure 2 is that the hazard rate function for the welfare history group lies below that for the non-welfare history group at all spell lengths. Unlike the exit rate plots for British Columbia, the hazard rates for the two groups in New Brunswick do not converge and the welfare group of UI claimants clearly has a lower exit rate than the non-welfare group. Therefore, the welfare group have a substantially longer expected UI spell duration in New Brunswick.

An alternative way to present the information on the duration of UI spells is by plotting the empirical survival curve. Figures 3 and 4 plot the empirical survival

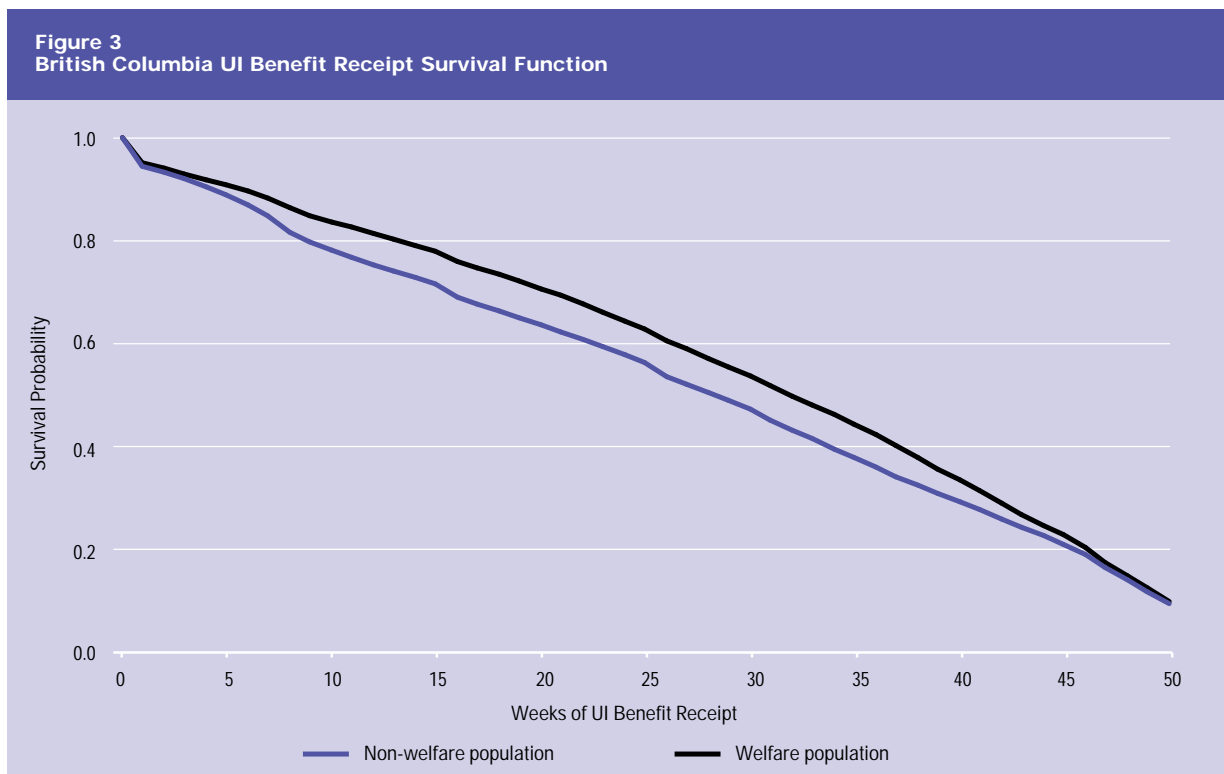

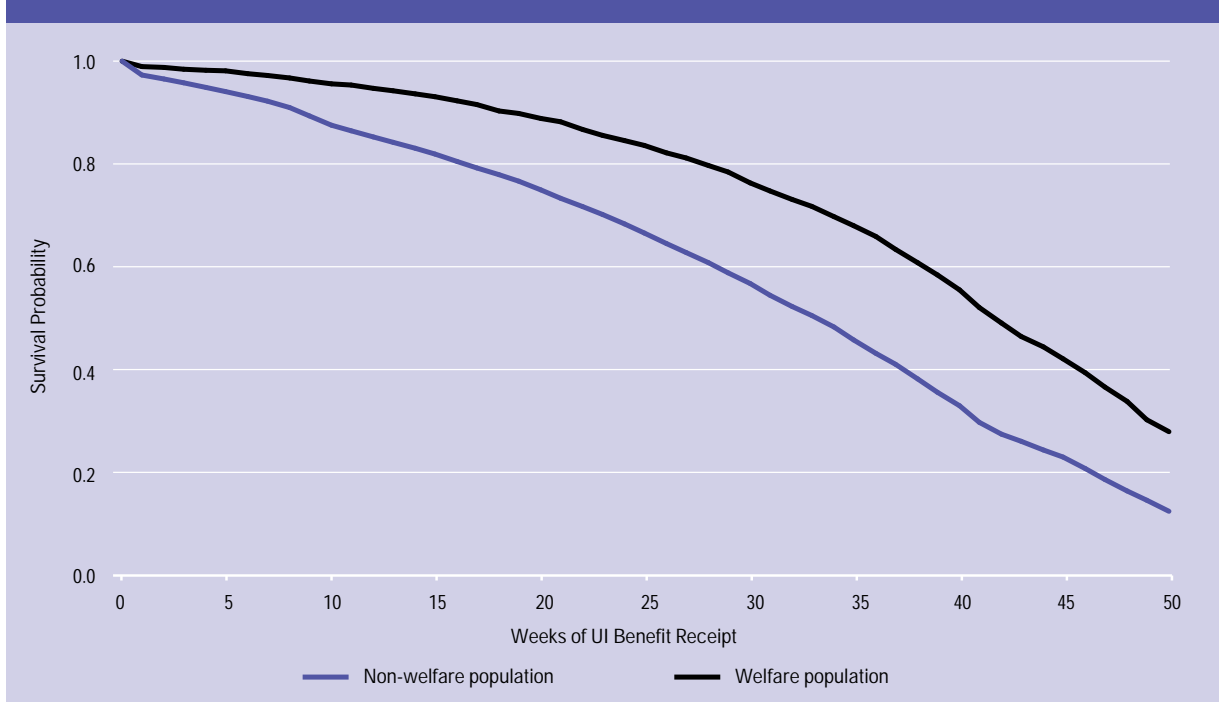

Figure 4
New Brunswick UI Benefit Receipt Survival Function

curves for the non-welfare and welfare history samples in British Columbia and New Brunswick, respectively. The survival curve plots show more clearly that the welfare history sample tend to have longer UI spells. Figure 3 shows that, in British Columbia, approximately half of the UI spells end within 28 weeks for the non-welfare history sample and within 32 weeks for the welfare history sample. However, as the exit rate is slightly higher for the welfare history group at longer durations, the survival curves converge over the 37–50 week range. One third of the spells by the non-welfare group are ongoing after 40 weeks; however, over 55 percent of spells by the welfare group remain in progress. The difference in the empirical hazard and survival curve plots for British Columbia is consistent with the welfare history group searching less intensively for employment during the initial weeks of a UI claim, but then either searching relatively more intensively or lowering their reservation wage more quickly as the spell progresses. The figures do not suggest that the welfare history group are substantially less likely overall to exit from UI than the non-welfare group in British Columbia, nor do they indicate a higher incidence of benefit exhaustion.

It is possible that the impacts of prior welfare receipt on UI spell durations are greatest for the set of individuals that have relatively greater entitlements under the welfare program. This would correspond to lone parent families, for whom welfare benefits are relatively more generous than for other family types.¹⁴ Figure 5

¹⁴ National Council of Welfare (1993) shows that in British Columbia (and most other provinces) lone parents with 2 or more dependent children and who qualify for welfare are financially better off on the program than working fulltime in a minimum wage job.

Figure 5
British Columbia UI Benefit Receipt Survival Function

presents the empirical survival curve plots respectively for the lone parent subset of the welfare history sample, relative to the non-welfare history group, in British Columbia. The figure shows that lone parents have longer expected UI spell durations than the average welfare history group; however, even this subset of the welfare history group does not appear to act substantially differently, in their use of UI, than the non-welfare history group in British Columbia.

Turning to New Brunswick, Figure 4 shows that approximately half of the UI spells end within 33 weeks for the non-welfare history sample and within 41 weeks for the welfare history sample. However, the survival curves do not converge over the longer durations. Figure 4 clearly shows that the two groups of UI claimants in New Brunswick do exhibit very different behaviour while on UI. The difference in the empirical hazard and survival curve plots for New Brunswick is consistent with the welfare history group searching less, or not decreasing their reservation wage as much, over the duration of the UI claim and hence experiencing a substantially higher incidence of benefit exhaustion.^{15,16}

The next step in the analysis is to take into account time until benefit exhaustion. The differences in the duration of UI spells may, in part, be due to differences in the length of benefit entitlements. Figures 6 and 7 illustrate the time until exhaustion empirical hazard rate function for the welfare and non-welfare history samples in

¹⁵ The results are also consistent with the welfare history group having more limited employment opportunities.

¹⁶ The sample size for the lone parent family subsample of the welfare history group in New Brunswick was too small for the empirical survival function to be estimated separately.

Figure 6
British Columbia Time Until UI Exhaustion Empirical Hazard

Figure 7
New Brunswick Time Until UI Exhaustion Empirical Hazard

British Columbia and New Brunswick, respectively. Note that these are not the same as Figures 1 and 2 with the time axis reversed, since there is variation in the length of benefit entitlement. For example, the risk set for the estimation of the time until exhaustion hazard rate at 30 weeks is given by the set of claims that have an entitlement of at least 30 weeks in duration and were not completed or right censored with more than 30 weeks of entitlement remaining.

The general shape of the hazard functions in Figures 6 and 7 are consistent with the search model and show a marked increase in the exit rate from UI as benefit exhaustion approaches. Figure 6 confirms that in British Columbia there is not a dramatic difference in the exit rate from UI for the welfare history group relative to the non-welfare history group. Conversely, Figure 7 shows that in New Brunswick the welfare history group do have lower exit rates from UI, even after controlling for initial entitlement, and are substantially more likely to remain on the program until benefits are exhausted.

Conclusions

This section examined the effect of prior welfare receipt on the duration of subsequent UI spells. We find that individuals who had received welfare in the two years prior to the UI spell tend to remain on UI longer (approximately 2 and 7 weeks longer in British Columbia and New Brunswick, respectively). After controlling for the maximum potential duration of benefits, it was found that in British Columbia the group with a recent welfare history had very similar exit rates from UI compared to the non-welfare history group. However, in New Brunswick the two groups exhibited very different behaviour, with the welfare history group exhibiting significantly lower exit rates from UI and a higher incidence of UI exhaustion. Therefore in New Brunswick, but not British Columbia, the prior receipt of welfare is associated with a substantially longer expected duration of subsequent UI spells.

The empirical analysis was motivated by a dynamic model of job search. The empirical findings for New Brunswick are consistent with the welfare history group having better knowledge of the welfare system and therefore searching less intensively, or not reducing their reservation wage, while on UI, relative to the non-welfare group. However, this is not the only possible explanation of the findings. As noted above, the hypothesis examined is also consistent with “scarring” effects of welfare receipt, through human capital depreciation or employer screening, on individual’s labour market opportunities. With the data examined in this study, it is not possible to determine the actual cause of the negative conditioning of welfare receipt on subsequent UI spell duration in New Brunswick.

The results of this study suggest several important avenues for future research on the interaction between UI and SA. Firstly, for the design of appropriate policy responses, it would be useful to test the competing explanations of the negative impact of welfare receipt on exit rates from UI in New Brunswick. Secondly, the findings of the analysis for New Brunswick contrast strongly with those for British Columbia; in the latter the welfare and non-welfare groups were found to have very similar behaviour. Therefore, it is important to understand why the results are so dramatically different; are the different findings due to differences in local labour market conditions or the characteristics of the welfare populations or perhaps differences in the operation of the welfare programs?

5. Conclusions

Most analyses of the labour market effects of social programs focus on one program at a time, in many cases on one or a few specific features of that program. Yet in designing public policy it is important to not only be aware of the behavioral effects of individual programs and policies, but also to take account of how the various components of the income security system interact with each other. As a consequence there is a need for research on the extent to which programs have a common set of participants and how any overlap in program participation affects behaviour.

Unemployment Insurance and social assistance are the two principal components of the Canadian income security system for the working age population. Although the effects of both programs have been analyzed separately (especially the effects of UI, which have been extensively investigated), there has been little previous research on the interaction between UI and SA. As a consequence there is a lack of even basic information about the extent to which the participants in the two programs overlap.

A principal objective of this study is to provide some of this basic information. The recent availability of administrative data on SA for five provinces, and the availability of UI administrative data, provides the opportunity to begin the analysis of UI-SA interaction in Canada. Unfortunately, the limited time period covered by the SA data for the provinces of Newfoundland, Prince Edward Island and Alberta implies that we can only provide a picture of how UI and SA interact in those provinces at a point in time, the early 1990s. The social assistance data for New Brunswick and British Columbia are available since 1986, and we are thus able to examine changes over the 1986–92 period — a period which includes the strong economic growth of the 1980s and the severe recession of the early 1990s — in these provinces.

In analyzing the welfare files we find that a large proportion of welfare recipients have some attachment to the workforce and that there is a large overlap in the clientele of UI and SA. In 1992, the most recent year covered by our data and a year for which we have data for all five provinces, the proportion of welfare recipients who also had a UI claim open in the same year varied from approximately one-third in Alberta and New Brunswick to more than one-half in Prince Edward Island and Newfoundland. These results may understate the extent to which UI and SA provide income support to a common set of individuals and families for two reasons. First, we employed a limited time period of the same calendar year in our analysis. The proportion of welfare recipients who had a UI claim open in either the same or an adjacent calendar year would be larger still. Furthermore, because UI claims are associated with individuals and welfare claims with families, our matching of UI and SA participants misses some individuals who receive income support from both programs — specifically those UI recipients who are members of a family receiving welfare, but not the principal claimant in that family.

In our examination of the interaction between UI and SA in British Columbia and New Brunswick, we also find clear evidence of an upward trend over the 1986–92 period in the extent to which the programs serve a common group of participants.

An interesting finding is that this trend toward increasing overlap between UI and SA was evident during the 1986–89 period, as the economy approached a cyclical peak. Indeed, in the case of British Columbia, most of the growth in the program overlap occurred prior to the onset of the recession of the early 1990s; in New Brunswick as much of the growth occurred in the 1986–89 period as in the 1989–92 period.

We also find, as have other recent studies of welfare participation (such as Brown, 1994, and Barrett and Cragg, 1995), that there is a growing tendency for individuals with characteristics normally associated with high employability and strong labour market attachment — young single men and women and members of two parent families — to increasingly rely upon welfare. The clientele for which the SA programs were originally conceived and designed, the disabled and single parent families, accounted for a diminishing proportion of recipients over this time period. The growth in the overlap in the clientele of the SA and UI programs and the changing nature of the welfare caseload in Canadian provinces are two aspects of the same phenomenon.

Accompanying this change in the composition of the social assistance population was a substantial decline in the average duration of welfare spells. For example, in British Columbia average spell duration declined from more than 14 months in 1986 to 9.4 months in 1989 and to 6.7 months in 1992. Similar changes occurred in New Brunswick

A number of potential factors may have contributed to these trends. The recession of 1990–1992 clearly affected the labour market opportunities of many individuals and likely contributed to many long-term unemployed relying upon welfare. Reforms to the UI program that reduced the generosity of the program may have lead some individuals to rely more on welfare than UI. However, these two explanations both relate to changes which took place in the 1990s. Our examination of the behaviour of UI and SA in British Columbia and New Brunswick over the 1986–92 period makes clear that other factors must have been at work. Further research is required to determine the causes of the changes which occurred in the 1980s.

A good deal of policy attention focuses on the duration of UI and SA spells. For British Columbia and New Brunswick we are able to document the extent to which UI and SA participants overlap among spells of different durations. In both provinces the changing nature of the SA population has resulted in a distribution of welfare spells with a distinct bimodal nature. There are both a large number of very short spells and a smaller but nonetheless substantial number of very long spells. The UI-SA overlap is concentrated among the short spells; in both British Columbia and New Brunswick, more than half of the 1–3 month spells involve individuals with a UI claim in the same year.

This examination of the interaction between UI and SA according to the duration of SA spells has a potentially important policy implication. Researchers using SA data *alone* have observed that a large number of SA spells end relatively quickly, and have concluded from this observation that these individuals do not face significant labour market problems (Barrett and Cragg, 1995). However, because many of these individuals also experienced a UI claim prior to their welfare spell,

the duration of their period of receipt of income support is much longer than is indicated by the duration of their welfare spell alone. The brief nature of their period in receipt of SA may be a misleading indicator of the difficulties they face in obtaining employment.

A further dimension of the UI-SA interaction was revealed by examining the UI spell samples and dividing claimants according to their use of welfare. This analysis also points to a substantial overlap in participation in the two programs. In 1992, the proportion of UI claimants who received both UI and welfare in a limited time frame varied from 7 percent in New Brunswick and Newfoundland to 15 percent in British Columbia. The UI files matched to SA data also indicate growth in the extent to which the programs serve the same group of individuals over the 1986–92 period in British Columbia and New Brunswick. In both provinces, there is evidence of the two programs increasingly serving an overlapping clientele during the expansionary period of the late 1980s, with the trend continuing during the downturn of the early 1990s.

In the final step of the analysis, we examine a specific form of UI-SA interaction and find that SA participation is associated with substantially longer UI spells in New Brunswick but not British Columbia. The results of this analysis suggest several important avenues for future research on the interaction between UI and SA. Firstly, it would be useful to test competing explanations for the negative impact of SA receipt on UI exit rates in New Brunswick because the alternative explanations have different policy implications. Second, it is important to understand why the results for British Columbia and New Brunswick differ; are these differences due to differences in local labour market conditions, differences in the characteristics of the welfare populations in the two jurisdictions, or differences in the welfare programs themselves?

The evidence reported here suggests that the individuals who participate in both the UI and SA programs may differ in their labour market opportunities and behaviour from those who participate in only one program. However, further research is needed to better understand the sources of these differences. Do the differences mainly emanate from the demand side of the labour market, with individuals in depressed labour markets increasingly needing to rely on both programs for income support? Or do the welfare or UI programs have a “scarring” effect on people, with the programs themselves adversely affecting beneficiaries’ future labour market opportunities? Finally, are any work disincentive effects of each program exacerbated by the availability of and, in some cases, participation in both? We have begun the process of addressing these issues by providing basic summary information on the extent to which the two programs interact in practice in several Canadian provinces. We hope that this information will stimulate further research on the behavioral implications of the interaction between UI and social assistance in Canada.

List of UI Evaluation Technical Reports

Unemployment Insurance Evaluation

In the spring of 1993, a major evaluation of UI Regular Benefits was initiated. This evaluation consists of a number of separate studies, conducted by academics, departmental evaluators, and outside agencies such as Statistics Canada. Many of these studies are now completed and the department is in the process of preparing a comprehensive evaluation report.

Listed below are the full technical reports. Briefs of the full reports are also available separately. Copies can be obtained from:

Human Resources Development Canada
Enquiries Centre
140 Promenade du Portage
