## Canadä̀

#### Abstract

The total catch of eastern Georges Bank haddock in 2004 was 11,790 mt under a combined Canada/USA quota of $15,000 \mathrm{mt}$. The 2004 Canadian catch increased from 6,873 mt in 2003 to $9,838 \mathrm{mt}$ while the USA catch increased from 1,627 mt in 2003 to 1,952 mt. Estimated discards from the Canadian scallop fishery and USA groundfish fishery were revised from the previous assessment and were very low relative to the total catch. Eastern Georges Bank haddock catches fluctuated around $5,000 \mathrm{mt}$ during 1985-1990. Under restrictive management measures, combined Canada/USA catches declined from over 6,500 mt in 1991 to a low of about 2,100 mt in 1995, averaged about 3,600 mt during 1996-1999 and have increased since then.

Adult population biomass has steadily increased from near an historical low of about 9,000 mt in 1993 to about $74,000 \mathrm{mt}$ in 2003 . Adult biomass subsequently decreased to about $50,000 \mathrm{mt}$ at the beginning of 2005 but is projected to increase after 2006 to well beyond the 1931-1955 maximum biomass of about $90,000 \mathrm{mt}$. The 2003 year class is estimated to be 365 million age- 1 fish. Although the current estimate is substantially lower than the previous year's estimate, the 2003 year class is still estimated to be the largest ever observed in the assessment time series. The 2000 and 1998 year classes are also strong. In contrast, the 2001 and 2002 year classes are weak and initial estimates of the 2004 year class suggest it is also relatively weak. Fishing mortality has been below the reference threshold ( $\mathrm{F}_{\text {ref }}$ ) of 0.26 since 1995. Reduced fishing mortality and lower bycatches of juveniles have increased haddock survival rates and led to greater abundance of older fish. The population age structure shows full representation of all age classes. Productivity has diminished in recent years due to reductions in average fish size at age.

With an assumed total catch of $23,000 \mathrm{mt}$ in 2005, a combined Canada/USA catch of $22,000 \mathrm{mt}$ in 2006 would result in a neutral risk (50\%) that fishing mortality in 2005 would exceed $F_{\text {ref. }}$ A catch of $18,000 \mathrm{mt}$ would result in a low risk (25\%) that fishing mortality in 2005 would exceed $\mathrm{F}_{\text {ref }}$. Catches in 2007 are expected to increase substantially as the 2003 year class becomes more fully recruited to the fishery.

## RÉSUMÉ

En 2004, les prises totales d'aiglefin du banc Georges se sont chiffrées à 11790 tm , par rapport à un quota combiné Canada/États-Unis de 15000 tm . Les prises canadiennes, qui étaient de 6 873 tm en 2003 ont augmenté à 9838 tm , tandis que les prises des États-Unis ont, elles aussi, connu une hausse, passant de 1627 tm en 2003 à 1952 tm en 2004. Le chiffre estimé des rejets de la pêche canadienne du pétoncle et de la pêche américaine du poisson de fond a été revu par rapport à l'évaluation précédente et ces rejets se sont avérés très bas par rapport aux prises totales. Les prises d'aiglefin dans l'est du banc Georges ont fluctué alentour de 5000 tm de 1985 à 1990. Suite à l'adoption de mesures de gestion restrictives, les prises combinées du Canada et des États-Unis ont diminué, passant de plus de 6500 tm en 1991 à un seuil d'environ 2100 tm en 1995, puis elles se sont situées en moyenne alentour de 3600 tm de 1996 à 1999 et elles ont augmenté depuis.

La biomasse de la population adulte a constamment augmenté après être tombée à environ 9 000 t , presque un seuil historique, en 1993 et elle s'est chiffrée à environ 74000 tm en 2003. Elle a ensuite diminué à environ 50000 tm au début de 2005, mais on prévoit qu'elle augmentera après 2006, au point de se situer bien au-delà de la biomasse maximale de la période 1931-1955, soit environ 90000 tm . On estime que la classe d'âge de 2003 est d'environ 365 millions de poissons d'âge-1. Bien que cette estimation soit sensiblement plus basse que celle de l'an dernier, elle fait encore de la classe d'âge de 2003 la plus grande classe d'âge observée dans la série chronologique de l'évaluation. Les classes d'âge de 2000 et 1998 sont également fortes. En revanche, celles de 2001 et 2002 sont faibles, tandis que les estimations initiales de la classe d'âge de 2004 laissent croire qu'elle est aussi relativement faible. La mortalité par pêche s'est située sous le seuil de référence (Fréf) de 0,26 depuis 1995. La baisse de la mortalité par pêche et des prises accessoires de juvéniles ont accru les taux de survie de l'aiglefin et abouti à une plus grande abondance de vieux aiglefins. Toutes les classes d'âge sont pleinement représentées dans la structure d'âges de la population. La productivité a baissé ces dernières années par suite de la diminution de la taille moyenne du poisson selon l'âge.

Si on se fonde sur des prises hypothétiques totales de 23000 tm en 2005, des prises combinées Canada-États-Unis de 22000 tm en 2006 se traduiraient par un risque neutre (50 $\%$ ) que la mortalité par pêche en 2005 soit supérieure à Fréf. Des prises de 18000 tm se traduiraient par un faible risque ( 25 \%) que la mortalité par pêche en 2005 dépasse Fréf. On s'attend à ce que les prises augmentent notablement en 2007 en raison du plein recrutement à la pêche de la classe d'âge de 2003.

## INTRODUCTION

Since 1990, Canada uses eastern Georges Bank, statistical unit areas j and m in NAFO sub-division 5Ze (Figure 1), as a haddock management unit (Gavaris 1989), referred to as "5Zjm". Canada and the USA jointly develop management measures for Georges Bank transboundary stocks including haddock. The 5Zjm management unit was adopted as the basis for a harvest allocation proposal for the two countries (DFO 2002). This assessment applies the approach used by Van Eeckhaute and Brodziak (2004) using Canadian and USA fisheries information updated to 2004. Results from the Fisheries and Oceans Canada (DFO) survey, updated to 2005, and the USA National Marine Fisheries Service (NMFS) surveys in the spring, updated to 2005, and fall, updated to 2004, were incorporated.

## FISHERY

## Commercial Catches

Haddock on Georges Bank have supported a commercial fishery since the early 1920s (Clark et al 1982, Gavaris and Van Eeckhaute 1998). Catches during the 1930s to 1950s ranged between $15,000 \mathrm{mt}$ and $40,000 \mathrm{mt}$ (Figure 2), averaging about 25,000 mt (Schuck 1951, R. Brown pers. com.). Records of catches by unit area for the early 1960s period have not been located, however, based on records for NAFO Subdivision 5Ze, catches probably attained record high levels of about $60,000 \mathrm{mt}$ during the early 1960s. Catches in the late 1970s and early 1980s, ranging up to about $23,000 \mathrm{mt}$, were associated with good recruitment. Substantial quantities of small fish were discarded in those years (Overholtz et al 1983). Catches subsequently declined and fluctuated around $5,000 \mathrm{mt}$ during the mid to late 1980s. Under restrictive management measures, combined Canada/USA catches declined from over 6,500 mt in 1991 to a low of about 2,100 mt in 1995, fluctuated between about $3,000 \mathrm{mt}$ and $4,000 \mathrm{mt}$ until 1999 and increased to $11,790 \mathrm{mt}$ in 2004 (Table 1, Figure 3). In 2004, the Canadian catch was $9,838 \mathrm{mt}$ and the USA catch was $1,952 \mathrm{mt}$ under quotas of $9,900 \mathrm{mt}$ for Canada and $5,100 \mathrm{mt}$ for the USA.

Quotas are the principal means used to regulate the Canadian groundfish fisheries on Georges Bank. Canadian catches since 1995 were below the quota due to closure of some fleet sectors when the cod quotas were reached, except for the year 2000 when the catch of $5,402 \mathrm{mt}$ was slightly above the Canadian quota of $5,400 \mathrm{mt}$. Quota regulation requires effective monitoring of fishery catch. Weights of all Canadian landings in 2004 were monitored at dockside and at-sea observers monitored 12\% by weight of the haddock caught in 2004. Discarding and misreporting of haddock by the groundfish fishery have been considered negligible since 1992. During 1994-2004, all Canadian groundfish fisheries on Georges Bank were closed from January to early June.

In recent years, the Canadian fishery has been conducted primarily by vessels using otter trawls and longlines with some handlines and gillnets. During 2004, otter trawlers under 65 ft and fixed gear vessels $45-65 \mathrm{ft}$ operated on individual quotas while fixed gear vessels under 45 ft operated on community quotas administered by local boards (Table 2). Vessels over 65 ft operate on Enterprise Allocations, which are company quotas. Smaller vessels are allowed to fish the quota which has been allocated to the larger vessels under the Temporary Vessel Replacement Program (TVRP) and increasing amounts of this quota have been taken by the TVRP boats in recent years. In 2004, 80\% of the catch was taken by tonnage class 2 and 3 (less than 150 tons) vessels less than 65 ft in overall length. Otter trawls took $80 \%$ of the
haddock and longliners took 20\% (Table 3). The highest catches in 2004 occurred during July and August (Table 4, Figure 4).

Canadian landings until 1995 include those catches reported by the scallop fishery but, since 1996, this fishery has been prohibited from landing haddock and this species was then discarded. Landed haddock bycatch, when landings were allowed, was low with a maximum of 38 mt reported in 1987 (Table 3). Estimates of scallop fishery discards were revised from what was reported in the previous assessment (Van Eeckhaute and Brodziak, 2004). Discards of haddock for 1969 to 1995 by the Canadian scallop fishery were estimated from scallop effort data and a discard per scallop gear tow-hour estimated from eight observed scallop trips conducted during 1991 to 1995. No scallop effort data was available for 1969 to 1971 so discards were estimated using the haddock discard rate per scallop landed estimated from the same eight observed scallop trips and prorated to the total scallop landings for these three years. Discards ranged between 69 and 186 mt from 1969 to 1995. Discards of haddock from this fishery for 1996 to 2004 were estimated from scallop effort data and bycatch rates from five observed trips conducted in 1995, 1996, 1997 and 1998 and from eight observed trips in 2001, three in 2002 and five in 2004. A seasonal component was apparent from the 2001, 2002 and 2004 trips and was incorporated into the bycatch rates for 1996 to 2004. In these years the discard estimates ranged between 29 and 102 mt , lower than most values reported before 1996 due to lower effort in the scallop fishery. Greater detail on the methods and results can be found in Van Eeckhaute et al 2005.

USA haddock catches for 2004 were derived from mandatory dealer reports and fishing vessel logbooks using the same procedures as for 1994-2003. The USA fishery has been regulated using trawl mesh size increases, closed areas, days-at-sea limits, daily catch limits and trip limits (Table 2). Trip limits were introduced in 1994 and daily catch limits in 1996 to reduce fishing mortality. Low trip limits in the mid-1990s resulted in an increase in discards which were included in the USA catch at age data for 1994 to 1998. Trip limits have been increased periodically to reduce discarding of haddock and improve haddock yields. Otter trawl gear accounted for the vast majority of USA discards (>99\%) while other gears such as scallop dredges, accounted for less than $1 \%$ of the total USA haddock discards. Discards have remained low because of high trip limits combined with larger trawl mesh size. Discards for 2001 to 2003 were estimated at 40, 35 and 63 mt , respectively and are included in the catch at age. The combination of area closures, effort restrictions, and trip limits reduced USA fishing effort in 5Zjm, with the result that USA catches from 5Zjm were relatively low from 1993 to 2000. Even though Area II was closed, landings from 5Zjm, which come almost exclusively from tonnage class 3 and 4 otter trawlers ( 51 to 500 tons), nearly tripled from 604 mt in 2001 to $1,796 \mathrm{mt}$ in 2004, averaging 1,200 mt during 2001-2004 (Table 5). In 2004, due to limits on the cod quota, 5Zjm was closed to USA groundfish vessels on Oct. 1. A haddock Special Access Program (SAP) was in place from Nov. 19 to Dec. 31 which allowed fishing outside of Closed Area II. As a result, catches were much lower than the USA quota of $5,100 \mathrm{mt}$ and were 1,952 mt , of which 156 mt were estimated as discards. USA catches by month have not been available since mandatory reporting began in 1994 (Table 6). Quarterly USA landings totals in 2004 were: 266 (15\%), 1196 (67\%), 309 (17\%) and 25 mt (1\%) (Table 7). USA landings were divided into 372 mt (21\%) large, 1411 mt (79\%) scrod and 12 mt (1\%) unclassified market categories.

## Size and Age Composition

The size and age composition of the 2004 Canadian groundfishery was characterized using port and at-sea samples from all principal gears and seasons. Comparison of port and atsea length frequencies did not reveal any persistent differences (Figure 5), therefore, all data
were combined (Table 8). The size composition of catch in the Canadian fisheries peaked at 50.5 to 52.5 cm (20-21 in) for otter trawlers and at 54 cm (21 in) for longliners (Figure 6). Gillnetters caught few haddock but these fish were larger. The percentage of haddock below 43 cm was less than $1 \%$ in the groundfish fishery.

Scallop fishery discards in 2004 quarters (Q) 3 and 4 could be characterized by length samples obtained by observers on trips conducted during August to December. To characterize all other time periods, a comparison was conducted between relevant survey and groundfishery length frequencies and the available haddock length frequencies from observed scallop trips (Figure 7). Scallop fishery length frequencies obtained by observers were available from 1995 (Q1), 2001 (Q2,3,4) to $2002(\mathrm{Q} 1,2)$ and $2004(\mathrm{Q} 3,4)$. The 1995, 2001 and 2002 data were compared to those from the survey area which most closely matched the scallop dredge fishing locations. For example, the 1995 dredge sets occurred almost exclusively in area 5Zj so only survey sets made in 5Zj, stratum $5 Z 2$ were used for comparison. The 2004 scallop dredge data were compared to the length frequencies from DFO and NMFS spring and fall surveys and the Canadian groundfishery data in the 5Zjm area. The quarter 1 comparisons indicated that scallop dredges failed to capture the smaller haddock observed in the surveys but this may be due to a lack of spatial coverage of the dredge data and the limited amount of data available from the scallop fishery since comparisons from other quarters show similar selectivity between survey and scallop dredge gear. Survey and scallop gear length frequencies were most similar for quarters 3 and 4 for which the greatest amount of data were available. The comparisons indicate that the size composition of the haddock taken in scallop gear is more similar to that in the surveys than to the commercial groundfish gear. Therefore, except for 2004 quarters 3 and 4 , in which adequate sampling was conducted, survey age composition was used to characterize the age composition of the scallop fishery discards. The average age composition of the DFO and NMFS spring surveys were used to characterize quarters 1 and 2 and the NMFS fall survey was used for quarters 3 and 4. The annual scallop fishery haddock discards are presented in Table 9.

Quarterly length samples from USA 5Zjm landings in 2004 were used to characterize the fishery length composition. Since no scrod samples were collected in quarters 1 and 4 and no large samples in quarter 4 (Table 7), size composition data were augmented by length samples from adjacent areas ( $522(5 \mathrm{Zh})$ and $525(5 \mathrm{Zn})$ ) with similar size compositions for these quarters. Quarterly age samples were also used to characterize the fishery age composition. USA age composition data were augmented with 2004 DFO survey data for quarter 1 and with the 2004 Canadian commercial fishery age length keys for quarters 2,3 , and 4 . The weight composition of the USA 5Zjm landings by market category was $21 \%$ large, peaking at 64 cm and $79 \%$ scrod, peaking at 53 cm , compared to 42\% large and 58\% scrod in 2003.

USA discards of eastern Georges Bank haddock in 2001 to 2004 were computed using quarterly age-length keys applied to quarterly discard length frequencies collected by at-sea observers. Approximately 9\% of USA landings of eastern Georges Bank haddock were sampled by at-sea observers in 2004 involving a total of 936 otter trawl hauls and 16 other fishing operations. As in recent years, the vast majority of USA discards was attributable to otter trawl gear (>99\%). Overall, USA discards of eastern Georges Bank haddock totaled 323.5 thousand fish in 2004. Of these, roughly $51 \%$ were age-1 fish from the exceptional 2003 year class.

Ages of survey and commercial-caught haddock were separately assigned by the DFO and the NMFS age readers, L. Van Eeckhaute and S. Sutherland, respectively. Intra-reader agreement tests for the DFO reader were not conducted in 2004 but testing conducted in 2003 indicated that age interpretations were internally consistent (Van Eeckhaute and Brodziak 2004). NMFS testing was conducted on data from the 2004 fall and 2005 spring NMFS surveys,

USA commercial landings in 2004 by quarter and a haddock otolith reference collection. The tests involved a total of 393 otoliths. Precision levels ranged between 91 and 98\% agreement between first and second readings with no pattern of seasonal bias, as was observed in the previous years testing, indicating a high level of consistency in age determinations. Agreement matrices are presented in Appendix A, Tables A1 to A7. Inter-reader testing between the NMFS reader and the DFO reader was completed in 2005 for 50 otoliths from the DFO 2004 spring survey and 50 otoliths from the Canadian commercial fishery. Agreement was very good at about 96\% (Tables A8 \& A9). Age reader agreement was judged to be satisfactory for estimating catch at age.

The 2004 Canadian and USA landings at age estimates by quarter (Table 10) were added to the 1969-2003 catch at age data (Van Eeckhaute and Brodziak 2004). The Canadian 2002 and 2003 and USA 2001 to 2003 landings at age were revised to reflect updated landings. Canadian discards and USA discards for 2001 to 2004 were also included. Combined Canada/USA annual catch at age and average Canadian fishery weights at age are summarized in Tables 11 and 12 and Figures 8 and 9. The 2000 year class (age 4) and the 1998 year class (age 6) dominated the fishery in 2004 (Figure 10). In comparison to the USA catch the Canadian catch contained more younger haddock, i.e., about $20 \%$ more haddock aged 4. This reflects a difference in the time of peak catches between the two countries. The majority of the Canadian catch is taken in quarter 3 while most of the USA catch occurs in quarter 2. The proportion of age 4 haddock caught by Canada increased from $36 \%$ in quarter 2 to $56 \%$ in quarter 3 and $65 \%$ in quarter 4 . Older age groups (ages 7,8 , and $9+$ ) also contributed significantly to the 2004 catch (Figure 10). The age composition during the 1969 to 1974 period was atypical since it was dominated by the outstanding 1962 and 1963 year classes which continued to contribute substantially at ages 6 and older.

## ABUNDANCE INDICES

## Research Surveys

Surveys of Georges Bank have been conducted by DFO each year (February) since 1986 and by NMFS each fall (October) since 1963 and each spring (April) since 1968. All surveys use a stratified random design (Figures 11 and 12). For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors (Table 13), derived experimentally from comparative fishing, have been applied to the survey results to make the series consistent. Additionally, two different trawl nets have been used on the NMFS spring survey, a modified Yankee 41 during 1973-81 and a Yankee 36 in other years, but no conversion factors are available for haddock (Forrester et al 1997).

The spatial distribution of catches by age group (1, 2, and 3+ for spring and 0, 1 and 2+ for fall) in the most recent surveys was plotted to show the distribution in comparison to the average over the previous 10 year period (Figures 13, 14 and 15). The 2003 year class at age 1 in the NMFS 2004 fall survey was abundantly and widely distributed as has been previously observed for large year classes. At age 2, the DFO 2005 February survey found this year class abundantly distributed on the northern edge, peak and southern flank while the NMFS 2005 spring survey found large catches on the northern edge and the southern flank. This year class was found in large quantities on the US side as well as the Canadian side, especially during the NMFS spring survey. The 2004 fall survey caught moderate catches of the 2004 year class at age 0 while catches of this year class at age 1 for both spring surveys were low. In fall, adult haddock are more concentrated in the deeper waters along the slopes of the Northeast Peak
and the Northern Edge. The 2004 fall survey got good catches of adult haddock in these areas. Large catches of adult haddock were observed on the Canadian side during the DFO 2005 spring survey. The NMFS 2005 spring survey caught fewer adults but they were somewhat more evenly spread out on both sides of the Bank, consistent with the trend usually observed for this survey.

Age-specific, swept area abundance indices show that the three surveys are consistent and track year class strengths well (Tables 14, 15 and 16; Figure 16). Some year effects are evident, however; for example, low spring catches occurred in both the 1997 DFO and NMFS surveys. All three survey series indicated that the 2003 year class is one of the strongest on record but spring survey catches in 2005 dropped substantially from the previous year. The NMFS fall survey gave a strong signal for the 2003 year class at age 1.

Survey biomass indices (ages 2-8 in fall; 3-8 in spring) peaked during the early 1960s (Figure 17). After declining to a record low in the early 1970s, they peaked again in the late 1970s, though at a lower level, and again during the mid to late 1980s at about half the level of the 1970s peak. Biomass generally increased during the 1990s. The DFO and NMFS spring 2005 biomass indices decreased substantially after being near record levels in 2004. A decrease was expected as the weak 2001 and 2002 year classes were anticipated to add very little biomass. The NMFS 2004 fall survey point was back up after showing a large drop in biomass in 2003.

Survey recruitment indices in 2003 and 2004 (ages 0 and 1) suggested that the 2003 year class was as abundant as the outstanding 1963 year class (Figure 18). However, survey results in 2005 indicate that this year class is not as large as initially indicated.

The abundance of the 2000 year class is comparable to the strong 1975 and 1978 year classes, with the 1998 year class being the third strongest since the 1978 cohort. The 1996 and the 1999 year classes are comparable to the moderate 1983, 1985, 1987 and 1992 year classes. These year classes are considerably smaller than the strong 1975 and 1978 year classes and the exceptional 1963 year class. The 2005 survey results suggest that the 2004 year class may be somewhat stronger than the weak 2001 and 2002 year classes.

## GROWTH

Fishery weights at age (Table 12, Figure 9) for ages 2 and 3 during the mid-1990s were generally higher than prior to the 1990s. This increase reflects a change in gear selectivity that occurred in the early 1990s. In 2004, fishery weights for all ages except age 1 declined from the low 2003 values and 2005 DFO survey weights also markedly declined (Table 17 and Figure 9). This trend in decreasing weights at age starter earlier for the older ages in both the fishery and DFO survey. The younger ages did not show this trend until about 2001. DFO survey lengths at age also show decreases and, except for age 5, declined in spring 2005 to their lowest values in the time series (Figure 19).

Average weights at age of haddock from the 1989, 1990 and 1991 year classes are higher than adjacent year classes in both the surveys and the commercial fisheries, giving the false impression of a declining trend in the years following. Weights at age from the DFO survey are considered beginning of year population weights and are calculated using the method in Gavaris and Van Eeckhaute (1998) in which weights observed during the survey are weighted by population numbers at length and age. Fishery weights at age are derived from the sampled lengths at age and a length-weight relationship (Waiwood and Neilson 1985). In some cases,
the mean weight at age in the catch was larger than the population mean weight at age at the beginning of the following year for the same cohort. This feature was mostly attributable to commercial fishery gear selectivity (Gavaris and Van Eeckhaute, 2000). However, some discrepancies in weights at age were more persistent and may be due to problems associated with the length-weight relationship and gutted-to-round weight conversion factors.

## HARVEST STRATEGY

The Transboundary Management Guidance Committee (TMGC 2003) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality limit reference, $\mathrm{F}_{\text {ref }}=$ 0.26 . When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding.

## ESTIMATION OF STOCK PARAMETERS

## Calibration of Virtual Population Analysis (VPA)

The adaptive framework, ADAPT, (Gavaris 1988) was used to calibrate the virtual population analysis with the research survey data. An investigation of model formulations and model assumptions was conducted by Gavaris and Van Eeckhaute (1998). They provide details for the established model formulation and objective function used in this assessment. Based on this formulation it was assumed that observation errors for the catch at age data were negligible. Observation errors for the abundance indices were assumed to be independent and identically distributed after taking natural logarithms of the values. The annual natural mortality rate, M , was assumed constant and equal to 0.2 . Similar model assumptions and methods were applied to the updated information here. Minor differences in the handling of zero terminal catches for a year class were implemented as a refinement to the software to afford more flexibility. The population abundance for the 9+ age group was calculated but not calibrated to the indices. In the first quarter of the first year, the 9+ abundance calculation was based on the assumption that the fishing mortality for the 9+ age group was equal to the population weighted fishing mortality for ages 4-8. In the first quarter of subsequent years, the 9+ abundance was calculated as the sum of the age 8 and age group 9+ abundances at the end of the last quarter of the previous year.

The VPA was based on quarterly catch at age, $C_{a, t}$, for ages $a=0,1,2 \ldots 8,9+$, and time $t=1969.0,1969.25,1969.5,1969.75,1970.0 \ldots 2004.75,2005.00$ where $t$ represents the beginning of the time interval during which the catch was taken. In previous assessments the catch at age contained no age 0 haddock since none were caught in the groundfish fishery. The inclusion of discards from the scallop fishery introduced age 0 fish into the catch at age. The effect of adding age 0 s to the catch at age was determined to be negligible and since the discards were poorly estimated and values were low, age 0 was set to zero in the analysis. Ages 1 and older discards were included in the catch at age. The effect on the population estimate of adding older discards was minimal. The population was calculated to the beginning of 2005.00. The VPA was calibrated to bottom trawl survey abundance indices, $I_{s, a, t}$, for

$$

$s=$ NMFS spring (Yankee 41), ages $a=1,2,3 \ldots 8$, time $t=1973.29,1974.29 \ldots 1981.29$
$s=$ NMFS fall, ages $a=0,1,2 \ldots 5$, time $t=1969.69,1970.69 \ldots 2004.69$
Since the population is calculated to beginning year 2005, the NMFS and DFO spring surveys in 2005 were designated as occurring at time 2005.00 The NMFS fall survey captures young of the year and that information is included as 0 group, but older haddock appear less available during this season. Survey indices for older ages where catches were sparse and where there were frequent occurrences of zero catches were not included (e.g., NMFS fall survey ages 6 and older and ages greater than 8 in the NMFS spring and the DFO surveys). Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. During years when discarding was high, survey information was used along with interviews to obtain estimates of the USA catch. This lack of complete independence between catch and survey data does not influence population estimates but may deflate variance estimates marginally.

Statistical properties of estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani 1993, Gavaris and Van Eeckhaute 1998). Population abundance estimates at age 1 exhibited a relatively large potential bias, had a relative error of about $60 \%$ and a potential bias of over $10 \%$, while the relative error for other ages was between about $25 \%$ and $40 \%$ with a potential bias between $1 \%$ and $7 \%$ (Table 18). The relative bias on fishing mortality for ages 4 and older in 2004 was small at about $2 \%$. While trends in the three surveys are generally consistent, the survey indices exhibit high variability and the average magnitude of residuals is large relative to other assessments. Although several large residuals were apparent, these do not appear to have a substantial impact on estimates of current abundance (Figures 20-24). Some patterns in the residuals (by cohort and by age) suggest year class and/or year effects.

## Retrospective Analysis

Retrospective analysis is used to detect a pattern of inconsistencies, where updates of previously estimated fishing mortality, biomass, and recruitment show a tendency to be systematically higher or lower. This stock assessment model, however, does not exhibit a retrospective pattern. While recruitment estimates may sometimes change substantially when more data becomes available, e.g., the 1998 and 2000 year classes, successive estimates of year class abundance at age do not display any persistent tendency to be higher or lower (Figure 25). Similarly, retrospective analysis showed no persistent patterns in the estimates of adult biomass (ages 3-8) or fishing mortality (ages 4-8 weighted by population numbers)
(Figure 26).

## STATE OF RESOURCE

The state of the resource was based on results from the calibrated age structured VPA. For each cohort, the terminal population abundance estimates from ADAPT were adjusted for bias estimated from the bootstrap, and used to construct the history of stock status (Tables 1920). This approach for bias adjustment, in the absence of an unbiased point estimator with optimal statistical properties, was considered preferable to using potentially biased point estimates (O'Boyle 1998). The weights at age from the DFO survey (Table 17) were used to calculate beginning of year population biomass (Table 21). A weight of 2.4 kg , which was midway between the age 6 and 8 weight for that cohort, was used for age 7 in 1995 as no data were available for that age group. The 1986-95 average weight at each age was used for 1969-
85. Data to approximate the age composition of the catch from unit areas 5 Zj and 5Zm were also available for the period between 1931 and 1955 to reconstruct an illustrative population analysis of eastern Georges Bank suitable for comparison of productivity.

Adult population biomass (ages 3+) during the late 1970s and early 1980s was about $40,000 \mathrm{mt}$, due to recruitment of the strong 1975 and 1978 year classes which were estimated to be about 50 million each (Figure 27). However, adult biomass declined rapidly in the early 1980s as subsequent recruitment was poor and these two year classes were fished intensely at young ages. Biomass steadily increased from a near record low of about 9,000 mt in 1993 to about 74,000 mt in 2003 but has since declined to about 50,000 mt ( $80 \%$ Confidence Interval: $40,500 \mathrm{mt}-63,000 \mathrm{mt}$, Figure 28, Table 21) at the beginning of 2005. The increase through the 1990s to 2003 was due to generally improved recruitment and was enhanced by lower exploitation and the reduced capture of small fish in the fisheries but two weak year classes, the 2001 and 2002, contributed to the reduction in adult biomass in 2004 and 2005. However, biomass is still near the upper range seen since 1969 and is within the range of the 1931-1955 biomass.

Recruitment improved in the 1990s and although the current estimate of 365 million age1 fish for the 2003 year class (Table 19) is substantially lower than the estimate in the previous assessment, the 2003 year class is still estimated to be the largest in the assessment time series (1931-1955 and 1969-2004) and will increase the adult biomass by 2006 to well beyond the 1931-1955 maximum biomass of about $90,000 \mathrm{mt}$. The 2000 year class ( 66 million at age 1 ) is estimated to be larger than the strong 1975 and 1978 year classes. The 1998 year class ( 28 million at age 1) is the third strongest since the 1978 cohort. The 1996 and 1999 year classes are estimated to be about 17 and 13 million, respectively, comparable to the 1983, 1985 and 1987 year classes, which were the strongest 3 year classes over about a 20 year time span. Two recent year classes, 2001 and 2002, are weak, at about 4 and 2 million fish, respectively, and first estimates of the 2004 year class are also low.

Fishing mortality for fully recruited ages 4+ fluctuated between 0.2 and 0.4 during the 1980s (Figure 29) and markedly increased between 1989 and 1993 to about 0.6, the highest observed, and subsequently declined to below the fishing mortality reference, $F_{\text {ref }}=0.26$, where it has remained since 1995 ( $F_{2004}=0.17$ : 80\% Confidence Interval: $0.13-0.21$, Figure 28).

Reduced fishing mortality in recent years has resulted in increased survival of recruiting year classes. The number of haddock of the 1992 year class surviving to age 8 was about four times that of the equally abundant 1983 year class, and about the same as that of the 1975 or 1978 year classes, which were more than 3 times as abundant (Figure 30). Avoidance of small fish by the fishery has resulted in increased survivorship at age 3 of the 1998 year class in comparison to the 1978 year class which was twice as strong.

Gains in fishable biomass may be partitioned into those associated with somatic growth of haddock, which have previously recruited to the fishery, and those associated with new recruitment to the fishery (Rivard 1980). We used age 2 as the age of first recruitment to the fishery. This choice facilitated comparisons with historic stock productivity but may be less representative of the current fishery selectivity. Except for 1996 and 2003, surplus production (biomass gains from growth and from recruitment, decremented by losses due to natural deaths) since 1993 has exceeded fishery harvest yields, resulting in net population biomass increases (Figure 31). Growth of fish is the dominant component of the biomass gain but recruitment accounts for significant portions when stronger year classes enter the population (Figure 32). The biomass contributed by the recruiting 2003 year class was greater than that of any other previous cohort.

## PRODUCTIVITY

Attributes like recruits per spawner, age structure and spatial distribution reflect possible fluctuations in the productive potential and can be used to qualify reference points and acceptable risk.

Stock-recruitment data indicates that the chance of a good year class is significantly enhanced for adult biomass above about 40,000 mt (Figure 35). Since 1969, only the 1975, 1978, 2000 and 2003 year classes have been above the average abundance of year classes observed during the period 1930-55. The recruits per adult biomass ratio was generally low during the 1980s but during the 1990s was comparable to that in the 1931-1955 period (Figure 34). Since 2000, two of the ratios were among the highest seen since 1931. The recruits per adult biomass ratio suggests that higher recruitment is likely to occur when the biomass is above 40,000 t.

Since 1995, a broad representation of age groups is apparent, reflecting improved recruitment and lower exploitation, particularly at younger ages (Figure 35).

Spatial distribution patterns observed during the most recent bottom trawl surveys are similar to the average patterns over the previous ten years. However, consistent with the pattern observed for previous large year classes, the exceptional 2003 year class at ages 1 and 2 as well as at age 0 was widely distributed throughout the survey area.

DFO survey average weights at length, used to reflect condition, show a decrease for smaller haddock ( 48 to 53 cm ) during the last 2 years and a longer trend is evident for larger fish ( 68 to 73 cm ). For these lengths, weights are at or near their lowest values in the DFO survey time series (Figure 36). The percent change in weight at length for 2002, 2003 and 2004 from the DFO survey indicate a decline in condition for most lengths during 2004. Some reduction in condition occurred during 2002 and 2003, especially for the smaller lengths but the data were more variable in these years (Figure 37).

In summary, productivity has increased since the 1980s due to improved recruits per spawner and increases in the number of larger and older fish in the population. Productivity has diminished in recent years due to reductions in average fish size at age.

## PARTIAL RECRUITMENT TO THE FISHERY

The significant reduction in weights at age and the decline in condition are reflected in a reduction in partial recruitment to the fishery. The average partial recruitment for 2002 to 2004 shows a large decrease in partial recruitment for ages 3 and 4 (Figure 38). The partial recruitment values used to estimate the 2005 catch in the previous assessment (Van Eeckhaure and Brodziak 2004) were based on ages 4-8 fully recruited. This revised partial recruitment pattern will have a significant impact on estimates of the magnitude and composition of future catches.

## OUTLOOK

The outlook is provided in terms of the possible consequences for alternative catch quotas in 2006 with respect to the harvest reference points. Uncertainty about standing stock
generates uncertainty in forecast results. This uncertainty is expressed in the outlook as the risk of exceeding $F_{\text {ref }}=0.26$.

Stock size estimates at the beginning of 2005 were used to start the forecasts. Abundances of the 2005 and 2006 year classes were assumed to be 20 million at age 1. For each forecast, partial recruitment to the fishery for ages 1, 2, 3 and 4 and fishery weights at age were set to their averages during 2002-2004. Population weights at age were set to their observed 2005 values from the DFO survey (Table 22). It was also assumed that the eastern Georges Bank total allowable catch (TAC) of 23,000 mt was caught in 2005. Natural mortality was assumed to be 0.2.

Given these forecast assumptions, a combined Canada/USA catch of 22,000 mt in 2006 would result in a neutral risk (50\%) that fishing mortality in 2006 will exceed $F_{\text {ref }}=0.26$. A lower catch of $18,000 \mathrm{mt}$ would produce a low risk (25\%) that the fishing mortality in 2006 will exceed $\mathrm{F}_{\text {ref }}$ (Figure 39). The 2003 year class (age 3) will comprise the highest proportion of the total 2005 yield, accounting for about half of the catch at the $22,000 \mathrm{mt}$ level. The 2000 year class will account for the second highest proportion ( $27 \%$ of the catch biomass).

The accuracy of the risk calculations depend on model assumptions and data. Though these assumptions are judged to be reasonable, other factors not considered could generate additional uncertainty. In particular, the calculations do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting, or the possibility that the model may not sufficiently reflect the dynamics of the stock. In this context, the risk profiles indicate the range of uncertainties and the consequences of alternative catch quotas.

Medium term projections were also conducted. In these forecasts (2006 to 2009), it was assumed that the stock would be exploited at a constant fishing mortality rate of 0.26 and the catch in 2005 would be $23,000 \mathrm{mt}$. Weights at age and partial recruitment were those used for the short term projection (Table 22). Recruitment was assumed to equal either the most recent 10-year average ( 20 million at age 1, excluding the 2003 year class) or the average recruitment which occurred during the period 1931 - 1955 average ( 40 million at age 1) when the stock was at a more productive level. Under either scenario, catches and biomass would be maintained at high levels through 2009 (Tables 23 and 24). Differences in projected total biomass, adult biomass and yield under the two recruitment scenarios are minimal.

## SPECIAL CONSIDERATIONS

Consistent management by Canada and the USA is required to ensure that conservation objectives are not compromised.

The outstanding 2003 year class will dominate the catch during 2006 to 2009. These catches are highly dependent on the magnitude of this cohort. Measures should be taken to avoid wastage of this year class due to discarding.

Several factors have resulted in a marked decrease in the estimates of biomass and future catch levels compared to the previous assessment. The significant decrease in weights at age and condition, which are also reflected in a reduction in partial recruitment to the fishery for ages 1 to 3 (age 4 is now also only partially recruited), along with a 2 to 3 fold reduction in the current estimate of the 2003 year class are responsible for this less optimistic outlook. If the TAC in 2005 is caught, fishing mortality will be higher than $F_{\text {ref }}$ due to the marked reduction in
weights at age and the reduced partial recruitment to the fishery of the 2003 year class at age 3 resulting in higher than predicted fishing pressure on the fully recruited older ages ( $F_{5_{+}}=0.39$ ).

Cod and haddock are often caught together in groundfish fisheries, although their catchabilities to the fisheries differ and they are not necessarily caught in proportion to their relative abundance. With current fishing practices and catch ratios, the achievement of rebuilding objectives for cod may constrain the harvesting of haddock. Additional efforts to protect the 2003 cod year class which, from first indications, is estimated to be larger than has been seen in recent years are warranted. Modifications to fishing gear and practices, with enhanced monitoring, may mitigate these concerns.

## ACKNOWLEDGEMENTS

G. Donaldson, S. D'Entremont and Javitech Ltd. provided samples from the Canadian fishery. We thank members of the fishing industry who spent time to discuss their experiences in the fishery. We also thank Stacey Paul, William Overholtz and Fred Serchuk for providing valuable comments on the draft manuscript.

[^0]Table 2. Regulatory measures implemented for the $5 Z$ and 5Zjm fishery management units by the USA and Canada, respectively, from 1977, when jurisdiction was extended to 200 miles for coastal states, to the present.

|  | USA | Canada |
| :---: | :---: | :---: |
| 1977-82 | Mesh size of $51 / 8^{\prime \prime}$ ( 140 mm ), seasonal spawning closures, quotas and trip limits. |  |
| 1982-85 | All catch controls eliminated, retained closed area and mesh size regulations, implemented minimum landings size ( 43 cm ). | First 5Ze assessment in 1983. |
| $\begin{aligned} & 1984 \\ & \text { Oct. } \end{aligned}$ | Implementation of the 'Hague' line . |  |
| 1985 | $51 / 2^{\prime \prime}$ mesh size, Areas 1 and 2 closed February-May. |  |
| 1989 |  | Combined cod-haddock-pollock quota for 4X5Zc |
| 1990 |  | 5Zjm adopted as management unit. For MG < 65 ft . - trip limits with a $30 \%$ bycatch of haddock to a maximum of 8 trips of 35,000 lbs per trip between June 1 and Oct. 31 and 130 mm square mesh required. Fixed gear required to use large hooks until June |
| 1991 | Established overfishing definitions for haddock. | MG < 65 ft similar to 1990 but mesh size increased to 145 mm diamond. |
| 1992 |  | Introduction of ITQs and dockside monitoring. Total allowable catch $(T A C)=$ 5000 mt . |
| 1993 | Area 2 closure in effect from Jan 1-June 30. | OT fishery permitted to operate in Jan. and Feb. <br> Increase in use square mesh. TAC $=5000$ mt. |
| 1994 | Jan.: Expanded Area 2 closure to include June and increased extent of area. <br> Area 1 closure not in effect. <br> 500 lb trip limit. <br> Catch data obtained from mandatory log books combined with dealer reports (replaces interview system). <br> May: 6" mesh restriction. <br> Dec.: Area 1,2 closed year-round. | Spawning closure extended to Jan. 1 to May 31. <br> Fixed gear vessels must choose between $5 Z$ or $4 X$ for the period of June to September. Small fish protocol. Increased at sea monitoring. OT > 65 could not begin fishng until July 1. Predominantly square mesh by end of year. TAC $=3000 \mathrm{mt}$. |
| 1995 |  | All OT vessels using square mesh. Fixed gear vessels with a history since 1990 of 25 t or more for 3 years of cod, haddock pollock, hake or cusk combined can participate in $5 Z$ fishery. <br> ITQ vessel require at least 2 t of cod and 8 t of haddock quota to fish Georges. TAC $=2500$ mt. |
| 1996 | July: Additional Days-at-Sea restrictions, trip limit raised to 1000 lbs. | Fixed gear history requirement dropped. TAC $=4500 \mathrm{mt}$. |
| 1997 | May: Additional scheduled Days-at-sea restrictions. <br> September: Trip limit raised to 1000 lbs/day, maximum of $10,000 \mathrm{lbs} /$ trip. | Vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft on individual quotas, fixed gear vessels 45-65 ft on self-administered individual quotas and fixed gear vessels under 45 ft on community |

|  | USA | Canada |
| :---: | :---: | :---: |
|  |  | quotas administered by local boards. TAC = 3200 mt . |
| 1998 | Sept. 1: Trip limit raised to $3000 \mathrm{lbs} /$ day, maximum of $30,000 \mathrm{lbs} /$ trip. | Fixed gear vessels $45-65 \mathrm{ft}$ operated on individual quotas. TAC $=3900 \mathrm{mt}$. |
| 1999 | May 1: Trip limit 2,000 Ibs/day, max. 20,000 lbs/trip. <br> Square mesh size increased to 6.5" (diamond is 6 "). <br> June 15: Scallop exemption fishery in Closed Area II. <br> Nov. 5: Trip limit 5,000 Ibs/day, max. 50,000 lbs/trip. | TAC $=3,900 \mathrm{mt}$. |
| 2000 | October: Daily trip limit suspended to April 2001but retained max. trip limit of 50,000 lbs/trip. | TAC $=5,400 \mathrm{mt}$. |
| $\begin{aligned} & 2001- \\ & 2002 \\ & \hline \end{aligned}$ | Day and trip limit adjustments. Daily trip limit suspended July 5, 2002. | TAC $=6,989 \mathrm{~m}$. and 6,740 mt for 2001 and 2002 respectively. |
| $\begin{aligned} & 2002- \\ & 2003 \\ & \hline \end{aligned}$ | 30,000 - 50,000 lb/trip limit. Trip limit suspended in Oct. 2003. | TAC $=6,933 \mathrm{mt} \mathrm{for} 2003$. |
| 2004 | May 1, day and trip limits removed. TAC = $5,100 \mathrm{mt}$. Oct. 1: 5 Zjm closed to groundfish vessels. Nov. 19: Special Access Program (SAP) for haddock opened. Dec. 31: Haddock SAP closed. | TAC $=9,900 \mathrm{mt}$. |
| 2005 | TAC= 7,590 mt. Jan. 14: Haddock separator trawl required. | TAC $=15,410 \mathrm{mt}$ |

Table 3. Canadian landings (mt) of haddock in unit areas 5Zjm during 1969-2004 by gear category and tonnage class for principle gears.

Table 15. Total swept area estimated abundance at age (numbers in 000's) of haddock for unit areas 5Zjm from NMFS spring surveys during 1968-2005. From 1973-81, a 41 Yankee trawl was used while a 36 Yankee trawl was used in other years. Conversion factors to adjust for changes in door type and survey vessel were applied.

Table 22. Risk projection input for haddock in unit areas 5Zjm for the 2006 fishery and projection input for the 2006 to 2009 fishery. A catch of $23,000 \mathrm{mt}$ in 2005 and $\mathrm{M}=0.2$ were assumed for the forecasts. Two projections were made, one using 20 million recruits for the 2005 to 2010 year classes, the other using 40 million.

Figure 2. Historical catch of haddock in 5Zjm during 1931-1955 compared to recent catches during 19692004.

Figure 3. Nominal catch of haddock in unit areas 5Zjm during 1969-2004.

Figure 4. Haddock catches in 5Zjm by month and gear for the Canadian commercial fishery in 2004 (wide gray bars) with sampling levels (narrow black bars).

Figure 5. Comparison of length frequencies obtained at port and at sea from the Georges Bank Canadian commercial fishery in 2004. The number of fish measured is shown in brackets.

Figure 6. Catch at length by the principal Canadian 5Zjm commercial haddock fisheries in 2004.

Figure 7. Comparison of haddock length frequencies by quarter from observed scallop fishery trips with survey and groundfishery length frequencies for scallop trips observed in 1995, 2001, 2002 and 2004. The 1995, 2001 and 2002 scallop dredge length frequencies were compared to that portion of the survey area which most closely matched the scallop dredge fishing locations. The 2004 dredge data were compared to the length frequencies from the 5Zjm area. The comparisons indicate that scallop gear length frequencies are more similar to those from survey gear than commercial groundfish gear.

Figure 8. Total commercial catch at age (numbers) of haddock from unit areas 5Zjm during 1969-2004. The bubble area is proportional to magnitude (see Table 11).

Figure 9. Average weights at age for haddock in unit areas 5Zjm from the Canadian commercial fishery during 1969-2004 and from the DFO survey during 1986-2005.

Figure 10. Age composition of the haddock catch for the 5Zjm commercial fishery in 2004 compared to the average age composition for the total catch of all fisheries during 1969-1974, 1975-1984, 1985-1994, and 1995-2003.

Figure 11. Stratification scheme used for NMFS surveys. The 5Zjm management area is indicated by shading.

Figure 12. Stratification scheme used for the DFO survey. The 5Zjm management area is indicated by shading.

Figure 13. Distribution of 5Zjm haddock abundance (number/tow) as observed from the DFO survey. The squares (left panels) are shaded relative to the average catch for 1995 to 2004. The expanding symbols (right panels) represent the 2005 survey catches.

Figure 14. Distribution of 5Zjm haddock abundance (number/tow) as observed from the NMFS spring survey. The squares (left panels) are shaded relative to the average catch for 1995 to 2004. The expanding symbols (right panels) represent the 2005 survey catches.

Figure 15. Distribution of 5Zjm haddock abundance (number/tow) as observed from the NMFS fall survey. The squares (left panels) are shaded relative to the average catch for 1994 to 2003. The expanding symbols (right panels) represent the 2004 survey catches.

Figure 16. Estimated abundance at age (numbers in 000's) of haddock for the DFO, NMFS spring and NMFS fall surveys during 1963-2005. Bubble area is proportional to magnitude (see Tables 14-16). Conversion factors to adjust for changes in door type and survey vessel were applied to the NMFS surveys. From 1973-81 (pale circles), a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years. Symbol size has not been adjusted between surveys for the catchability of the survey.

Figure 17. Biomass from NMFS fall (ages 2-8), NMFS spring (ages 3-8) and DFO (ages 3-8) research surveys (scaled by calibration constants, Table 18) for haddock in unit areas 5Zjm during 1963-2005.

Figure 18. Year-class abundance for ages 0 and 1 from the NMFS fall and ages 1 and 2 from the NMFS spring and DFO research surveys (scaled by calibration constants, Table 16) for haddock in unit areas 5Zjm during 1963-2005.

Figure 19. Length at age for haddock in unit areas 5Zjm derived from DFO surveys during 1986-2005.

Figure 20. Residuals by year and age group for research survey indices during 1969-2005. Solid symbols indicate positive values, open symbols indicate negative values. Bubble area is proportional to magnitude. From 1973-81 (pale circles), a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years.

Figure 21. Age by age plots of the observed and predicted In abundance index versus In population numbers for haddock in unit areas 5Zj and 5Zm from the DFO survey during 1986-2005.

Figure 22. Age by age plots of the observed and predicted In abundance index versus In population numbers for haddock in unit areas 5Zj and 5Zm from the NMFS spring survey with a Yankee 36 net during 1969-1972 and 1982-2005.

Figure 23. Age by age plots of the observed and predicted In abundance index versus In population numbers for haddock in unit areas 5Zj and 5Zm from the NMFS spring survey with a Yankee 41 net during 1973-1981.

Figure 24. Age by age plots of the observed and predicted In abundance index versus In population numbers for haddock in unit areas 5Zj and 5Zm from the NMFS fall survey 1969-2004.

Figure 25. Successive estimates of 5Zjm haddock year-class abundance as additional years of data were included in the assessment did not display any persistent trends.

Figure 26. Retrospective estimates from VPA of 5Zjm haddock biomass and fishing mortality did not display any persistent trends for over or under estimation as successive years of data were excluded in the assessment.

Figure 27. Beginning of year adult (3+) biomass and number of age 1 recruits for haddock in unit areas 5Zjm during 1931-1955 and 1969-2005.

Figure 28. Confidence distribution with $80 \%$ confidence intervals for 2005 5Zjm haddock ages 3+ biomass ( 000 mt ) and 2004 ages $4+$ fishing mortality.

Figure 29. Fishing mortality rate for haddock ages $4+$ in unit areas 5 Zjm and the fishing mortality threshold reference established at $\mathrm{F}_{\text {ref }}=0.26$ during 1969-2004.

Figure 30. Decline in abundance of selected year-classes of the 5Zjm haddock population.

Figure 31. Surplus production of 5Zjm haddock available to the commercial fishery compared to the harvested yield during 1969-2004.

Figure 32. Amount of productivity attributible to growth (ages 2 to $9+$ ) of 5Zjm haddock and the amount contributed by recruitment (age 2) during 1969-2004.

Figure 33. Relationship between adult (ages 3+) 5Zjm haddock biomass and recruits at age during 19311955 and during 1969-2004.

Figure 34. Ratio of recruits (numbers at age 1) to spawning biomass (kg) for 5Zjm haddock during 19311955 and during 1969-2004.

Figure 35. The age composition and absolute abundance at age of the 5Zjm haddock population in 2005 compared to averages during 1931-1955, 1969-1974, 1975-1984, 1985-1994, and 1995-2004.

Figure 36. DFO survey weights at lengths for haddock in 5Zjm for six 2 cm length groupings during 19862005.

Figure 37. Percent change in DFO survey weight at length for haddock in 5Zjm during 2002, 2003 and 2004.

Figure 38. Change in average recruitment pattern for 5Zjm haddock.

Figure 39. Risk of 2006 fishing mortality exceeding $\mathrm{F}_{\text {ref }}=0.26$ for 5Zjm haddock for increasing catch quotas. The 2002-2004 average fishery weights at age and partial recruitment pattern were used to predict the yield and the 2005 DFO average survey weights at age were used to estimate beginning year population biomass.
