## Canadian Manuscript Report of Fisheries and Aquatic Sciences 2544

## Canadian Manuscript Report of Fisheries and Aquatic Sciences

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-900 in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551 .

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport manuscrit canadien des sciences halieutiques et aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques ques qui constituent une contribution aux connaissances actuelles, mais qui traitent de problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministere des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports manuscrits sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annual des publications scientifiques et techniques du Ministère.

Les numéros 1 à 900 de cette série ont été publiés à titre de manuscrits (série biologique) de l'Office de biologie du Canada, et après le changement de la désignation de cet organisme par décret du Parlement, en 1937, ont été classés comme manuscrits (série biologique) de l'Office des recherches sur les pêcheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de rapports manuscrits de l'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

Les rapports manuscrits sont produits a l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

Nagtegaal, D. A. and E. W. Carter. 2000. Adult chinook escapement assessment conducted on the Cowichan River during 1999. Can. Manuscr. Rep. Fish. Aquat. Sci. 2544: 59 p.

In 1999, the Stock Assessment Division, Pacific Biological Station, conducted a study of chinook salmon (Oncorhynchus tshawytscha) productivity in the Cowichan River. This indepth adult escapement assessment project has been in place since 1988. Major components of this ongoing study include: i) enumeration of spawners and total return, ii) estimation of Native food fish catch, iii) recording hatchery broodstock removals, iv) biological sampling and coded-wire tag (CWT) recovery data collection. A carcass mark-recapture study was conducted to augment the fence count. Total return of adult chinook to the Cowichan River was estimated to be 6,392 in 2000. The number of natural spawners was estimated to be 4,500. Carcass mark-recapture escapement estimate of upper river spawners was determined to be 3,440 (95\% CL; 2,908-3,972).

## RÉSUMÉ

Nagtegaal, D. A. and E. W. Carter. 2000. Adult chinook escapement assessment conducted on the Cowichan River during 1999. Can. Manuscr. Rep. Fish. Aquat. Sci. 2544: 59 p.

En 1999, la Direction des sciences biologiques de la Station biologique du Pacifique a entamé une étude sur la productivité du saumon quinnat (Oncorhyncus tshawytscha) dans la rivière Cowichan. Cette étude, qui est toujours en cours, porte principalement sur : i) le recensement des reproducteurs ; ii) le volume de la pêche autochtone de subsistance ; iii) le recensement des spécimens de recrues issus d'écloserie ; iv) l'échantillonnage biologique et l'examen des micromarques magnétisées codées (MMC). Soulignons qu'une étude consistant à étiqueter les carcasses de reproducteurs pour qu'on les remette à l'eau afin de comparer le nombre de carcasses de reproducteurs étiquetées et non étiquetées a permis d'étayer les résultats obtenus aux barrières de comptage. Pour l'année 2000, l'effectif de remonte total du saumon quinnat adulte - écloseries et frayères naturelles confondues - dans la rivière Cowichan se chiffrait à 4500 , le nombre de reproducteurs issus de frayères naturelles étant estimé à 6 392. Enfin, les auteurs décrivent un plan de gestion des eaux destiné à faciliter la remonte du quinnat.

Considerable interest has been focused towards the chinook salmon (Oncorhynchus tshawytscha) stocks in the southern portion of the Strait of Georgia over the past several years due to the perceived decline in these stocks and their importance to the local fisheries (Farlinger et al. 1990). The Stock Assessment Division, Pacific Biological Station, initiated a study of chinook productivity to assess rebuilding strategies and to evaluate the effects of harvest management policies for these stocks. In the fall of 1988, a study was implemented on the Cowichan River chinook stock with additional information collected from the Squamish and Nanaimo River chinook stocks. These three stocks were identified as escapement indicators to represent the status of Lower Georgia Strait chinook stocks.

Hatchery production of chinook on the Cowichan River began in 1980 (Cross et al., 1991). Chinook fry releases have increased from 64,681 in 1980, to 2,543,136 in 1999. Marked releases also began in 1980 and in 1999 approximately $15 \%$ of the total number of chinook released were coded-wire tagged.

The objectives of this study include: i) to quantitatively determine the optimum spawning requirement for chinook salmon in the Cowichan River (this involved investigations of the determinants of juvenile production, interactions between hatchery and wild chinook, and estimation of the spawning escapement and catch attributed to the hatchery and wild components of the total run), and ii) to develop guidelines for establishing escapement targets for other B.C. chinook stocks (Nagtegaal et al.,1994a).

The purpose of this report is to present the results of the adult escapement enumeration component of the chinook productivity study conducted on the Cowichan River during the fall of 1999.

METHODS

Components of escapement enumeration include: i) enumeration of chinook salmon at the counting fence; ii) estimation/biological sampling of Native food fishery catch; iii) recording of hatchery broodstock removals; iv) collection of biological data and sampling of coded-wire tag (CWT) recoveries; and v) carcass mark-recapture studies for both adult and jack chinook.

A detailed description of the methodology used to collect the above information was presented in Nagtegaal et al. (1994b). Some changes were made in 1999 and are described below. The counting fence was placed in the same location as in previous years (Fig. 1).

ENUMERATION FENCE

A resistance board weir was installed with a counting raceway (adjustable flashboard) and trap box adjacent to the counting tower equipped with floodlights. Counts were continuously recorded for the duration of the operation by 15 minute intervals for adult and jack chinook, adult and jack coho, and chum. If identification was in doubt those fish were recorded as unknown. Water depth, temperature, and clarity, and weather conditions were recorded three times per day. On a daily basis the integrity of the fence was checked and cleaned of leaves and other debris. Records of broodstock collected at the fence by the hatchery staff were also kept.

SWIM SURVEYS

Swim surveys were conducted, in conjunction with Cowichan Tribes Aboriginal Fisheries Management (CTAF), to estimate the spawning population of chinook. The swims were made in the upper section of the river only (Fig. 1) and extrapolated to the total system. Each survey was conducted by three experienced swimmers and one person in a canoe who recorded the data. Each swimmer (one in the middle and one on each side of the river) counted the fish seen within their range of visibility. The three swimmers attempted to keep abreast as they approached each pool while the person in the canoe lagged behind within hailing distance. Counts were recorded by pool/riffle and then compiled by river section. When possible the same swim team was used for each survey to maintain consistency in counting procedures. Swim counts were expanded by a factor of 3.4, based on historical distribution of spawners, to derive an escapement estimate (Nagtegaal et al. 1994a). This expansion factor was consistently applied to swim counts with no adjustments made for run timing or the changes in the distribution of chinook in the river. A final escapement estimate was then determined in consultation with Fisheries and Oceans Canada Fishery Officers and based on other anecdotal information.

It was intended that the swim survey estimates remain independent of the fence count. Even though no fence count information was passed on to the swim teams during the season, general trends in escapement numbers were known.

## NATIVE FOOD FISHERY

In 1990, a systematic approach was developed by the Cowichan Tribes Aboriginal Fisheries Management (CTAF) program to monitor the fishery more closely and to better estimate the Native food fish catch (Paige 1992, 1997). This approach involved recording catch and effort by management zone within the Native fishing boundaries (Fig.2). A crew of four observers patrolled the fishery on a daily basis and interviewed fishermen for numbers caught by area and total time spent fishing. In this way, weekly estimates of catch per unit effort (CPUE) were obtained. CPUE was adjusted for daily changes in fishing effort and differences in effort among fishing zones. These data were then extrapolated over time and area to estimate total catch by week and summed over all weeks to estimate the total 1999 catch.

$$
C A T C H \equiv \sum_{n}^{w=1} C P U E_{w} \times E F F O R T_{d}
$$

where w refers to the time interval for catch (week), and d refers to the time interval for effort (day). No confidence limits were calculated (Paige 1997).

For some years since 1988, an observer was employed to independently collect catch and biological data from the in-river chinook spear fishery. Due to budget contraints no independent biosampling of the fishery was conducted in 1999.

## BIOLOGICAL DATA

Biological data for chinook were collected from two sources: i) hatchery broodstock samples; and ii) carcass mark/recapture (spawning grounds). Hatchery staff randomly collected biological data from approximately $25 \%$ of the chinook broodstock, recorded the incidence of coded-wire tagged (CWT) fish, and selectively sampled all additional CWT fish. On the spawning grounds chinook were sampled for post-orbital hypural ( POH ) length, sex, scale, spawning condition and the presence/absence of an adipose clip. All coded-wire tagged fish recovered were biosampled, the head removed and frozen for further analysis.

## MARK-RECAPTURE

A multiple mark-recapture program involving the tagging and subsequent recovery of chinook jack and adult carcasses was conducted on the spawning grounds (Sykes and Botsford 1986). All chinook carcasses were individually tagged with a Ketchum ${ }^{1}$ aluminum sheep ear tag on the
${ }^{1}$ Ketchum Manufacturing Ltd., Ottawa, Canada.
left operculum and immediately released in the same area as captured. Location of capture and release, tag number, spawning condition, length, sex, and adipose clip information were recorded for each carcass recovered. Tag numbers and location of previously marked carcasses were recorded and the carcass returned to the river in the same site as captured.

Two or three man crews in inflatable boats daily surveyed the upper section of the river (Fig. 1) and collected all available chinook carcasses. This section of the river above Skutz Falls represents the area where the majority of chinook spawning typically occurs. On two occasions, one of the crews collected carcasses from the middle section of the river (Fig. 1). A 4.2 m pole with a gaff hook attached to the end was used to recover carcasses. Some carcasses were likely missed if they ended up in pools too deep for retrieval.

POPULATION ESTIMATE

Adult chinook salmon escapement estimates were generated from the carcass mark-recapture data using the Petersen model (Chapman modification) stratified by sex and river section (Ricker 1975). As in past years, it was necessary to stratify the data in order to minimize the effects of differential tagging and tag recovery between sexes and river sections. This study follows the estimation procedure as outlined in previous reports (Nagtegaal et al. 1994a, 1994b, 1994c).

## RESULTS

ENUMERATION FENCE

In 1999, the counting fence was operated from Aug. 27 through to Oct. 30. Due to high water conditions at the end of the study the fence operation was terminated. Daily counts at the enumeration fence are contained in Table 1, and compared with water depth and temperature recorded at the fence (Fig. 3). Total counts recorded during this period were: 3,824 adult chinook; 1,291 jack chinook; 2,353 adult coho; 670 jack coho; 2,184 chum and 59 unidentified fish. During the last days of operation, the combination of heavy rain, increasing flow and muddy water made identification difficult. Only a few fish were observed passing over the submersed fence prior to removal.

In past years, especially during the early part of the season, more jack chinook have often been observed to enter the river than adult chinook. The numbers of jack chinook were particularly low and the ratio of jack to adult chinook was the lowest since the project began in 1988. Daily counts were summarized by one hour intervals (Table 2) and we note that peak movement of adult and jack chinook occurred between

0700 and 0900 and again between 2200 and 2400. Approximately 51\% of adults and $28 \%$ of jacks migrated past the fence during daylight hours.

During several shifts throughout the migration period an independent count was made at the enumeration fence to determine the accuracy of the counting procedure and species identification. On several occasions, fish were visually identified by an observer in the counting tower and then captured in the fish trap and identified by a second observer. Of the 150 fish examined, three fish (2\%) were incorrectly identified. Errors were made in mis-identification of jack or adult fish.

SWIM SURVEYS

A summary of visual surveys conducted by Fishery Officers and Cowichan Tribes Aboriginal Fisheries Management from 1981-1999 is presented in Table 3. Total escapement estimates for each year are for adult chinook only. Swims in 1999 were conducted in the upper section of the river (Birdhouse to Three Firs pool; Fig. 1) on Sept. 10 and Oct. 13. The 1999 escapement of adult chinook was determined to be about 5,000 based on the upper river swim counts. The two swim surveys were conducted under good conditions (low water and clear visibility).

NATIVE FOOD FISHERY

Estimates of the Native food fish catch of chinook since 1981 are listed in Table 4. The 1999 catch estimate of 233 adults and 89 jacks was determined by the Cowichan Tribes Aboriginal Fisheries Management group (Fig. 2). According to their observations, the adult chinook spear fishery was more successful than the catch estimates indicate, (Fig. 4) since low water conditions remained during the fishing season. Although it was very difficult to assess the quality of the data collected, the catch estimate was considered to be low. According to Aboriginal Fisheries Guardians the number of adult chinook taken in the spear fishery was likely 600-800 fish.

## HATCHERY COMPONENT

In 1999, 1,654 adult chinook were removed from the river by the Cowichan River hatchery staff below the enumeration fence (Table 5). The hatchery staff (D. Millerd, P.O. Box 880, Duncan, B.C., pers. comm.) indicated they had met their target this year (Table 6). Primarily three year old chinook were used for broodstock (Table 7).

BIOLOGICAL DATA
More adult male carcasses than female chinook were sampled on the spawning grounds (Table 8). Since conditions for recapture of carcasses was not optimal throughout the survey with higher flows experienced in November, larger and heavier (female) carcasses were more easily recovered. Most carcasses were recovered on the spawning grounds in the upper section and few from the middle section of the river. Mean size of females sampled was 65.7 cm post orbital hypural (POH) length and for males was $63.9 \mathrm{~cm}(\mathrm{POH})$. Adult chinook were primarily comprised of 3 and 4 year old fish (Table 9).

Length-frequency summaries of chinook broodstock collected and sampled at the hatchery are listed in Table 10 . The hatchery staff randomly sampled approximately $25 \%$ of all broodstock collected and then selectively sampled all remaining adipose-clipped chinook. The adipose mark rate in the random sample was $3.0 \%$ for males and $6.3 \%$ for females. The mark rate for chinook from hatchery samples was comparable to the mark rate observed on the spawning grounds.

Coded-wire tag recovery information for chinook sampled on the spawning grounds is listed in Table 11. A summary of chinook releases (Kuhn 1988) from the Cowichan hatchery by brood year is listed in Table 12. A cursory look at CWT recoveries on the spawning grounds relative to the total number of fish released indicated that the majority of recoveries were observed from tag groups released in the upper Cowichan (Road Pool) site.

ENVIRONMENTAL INFORMATION

Water flow and temperature measured at the fence site (Table 1) and discharge information recorded at the Water Survey Canada station below the Island highway bridge in Duncan (Table 13), indicated that river conditions during the fall of 1999 were quite typical (Inland Waters Directorate 1999). Compared to the 30 year mean (1960-90), water flow was near mean levels from August to December (Fig. 5) with average rainfall was recorded during this time.

## MARK-RECAPTURE

Table 14 contains a summary of the carcass mark-recapture data by tagging period. A total of 601 adult and one jack chinook carcasses were tagged and released in the upper river section and only 5 adults in the middle river section. More than $78 \%$ of the adult carcasses were tagged but never recaptured. Smaller and lighter male chinook carcasses are often more readily swept downstream and less likely to be recovered than the heavier female carcasses. Higher water conditions occurred in November and this often causes carcass retrieval to be difficult. This is often the case during the fall and a potential source of bias. This was especially evident in certain areas in the middle river section where cloudy water, due to riverbank erosion, made it particularly difficult to tag and retrieve adult and jack carcasses.

## Stratified Petersen

The escapement estimate of adults (excluding jacks) based on carcass mark-recapture data was 3,440 with lower and upper 95\% confidence limits of 2,908 and 3,972 , respectively (Table 15). This was based on the data from the upper section of the river only since few fish were tagged or recovered in the middle section. It was assumed that greater than $75 \%$ of the total escapement spawned in the upper river section.

## Potential biases

Some of the typical biases associated with mark-recapture experiments (Ricker 1975) are listed below and were examined in some detail for the carcass mark-recapture data. To minimize bias, fish tagging and recovery occurred concurrently and was stratified by sex and river location.

1. Temporal bias: Temporal bias in the tagging sample was examined by comparing the mark incidence between periods in the recovery sample (Table 16). There were no significant differences in the mark incidence between periods ( $\mathrm{P}>0.05$; chi-square; Zar 1984). Mark incidence was somewhat higher towards the end of the survey.

Recovery bias was examined by stratifying the application sample by period and comparing proportions recovered (Table 17). Significant differences were observed ( P < 0.05; chi-square). The highest percentage of tags was recovered towards the end of the study. This occurred even though tags were applied at a consistent rate during the study.
2. Location bias: Spatial bias was not examined between the upper and middle river sections due to insufficient sample size in the middle river section. This may have been due to the cloudy water conditions in this section which made carcass tag and recovery
difficult, although a few carcasses were found along the sides of the river. Erosion of some clay banks, which exist in this segment of the river, cause the water to be very cloudy and substantially reduce water visibility. Conditions further deteriorate due to high water.
3. Fish size: Size related bias in the application sample was examined by comparing the continuous POH length frequency distributions of marked and unmarked recoveries from the spawning ground. No significant differences were observed in males or females ( $D_{\text {obs }}<D_{\text {alpha }}$; Kolmogorov-Smirnov two sample test). Size related bias in the recovery sample was examined by comparing the continuous POH length frequency distributions of tagged and recaptured carcasses (Table 18). Again, no significant differences were observed in males or females ( $P>0.05$ ).
4. Fish sex: Sex related bias in the application sample was examined by comparing the sex ratio of the marked and unmarked spawning ground recoveries (Table 19). No significant differences were noted ( $\mathrm{P}<0.05$; chi-square). Bias in the recovery sample was examined by partitioning the application sample into recovered and non-recovered components and comparing the sex ratios in each. No significant differences were noted between the tag and recovery samples ( $\mathrm{P}<0.05$; chi-square). Often in high water conditions, fewer tagged males are recovered than females because the larger-bodied (heavier) females tend to remain in the tag area more readily than the lighter-bodied males that are more readily swept downstream. This was not the case, however, and it was simply a matter that fewer male carcasses were available to be tagged.

## DISCUSSION

## ENUMERATION FENCE

The floating fence design adapts well to the considerable changes in flow that occur during the fall on the Cowichan River. Although it was intended to be self-cleaning, field staff were required to maintain a regular cleaning schedule during times when leafy debris and flooding caused by heavy rains made it difficult for the fence to remain afloat. Due to the considerable number of deciduous trees along the banks of the river, a combination of wind, rain and leaves are the main causes of fence failure. This remains an ongoing problem that is very difficult to overcome (Cousens et. al., 1982; Johnston et. al.,1986).

In most years, the fence is removed due to high water towards the end of the chinook run and mark-recapture population estimates are used to corroborate the fence data and determine the total return. Enumeration data were collected for the time the fence was in full
operation. Although this was the period during which most chinook were presumed to have entered the river, we have no direct count of fish that may have entered before or after the fence was in place and need to rely on swim survey and mark-recapture information. Obviously, the fence count of 3,824 chinook adults and 1,291 jack chinook should be considered an incomplete count of the total run, but the most accurate one available for the time it was in operation. Since the daily count of chinook was minimal when the fence count began, we could assume that the run had just started and few fish had moved upstream past the fence site. Based on information from previous studies (1991-96) for upstream movement after Oct. 30, we estimate that approximately $15 \%$ of the run was still to come. If we extrapolate the adult fence on this basis we derive a total count of 4,397 adults.

## SWIM SURVEYS

Among the biases typically associated with swim surveys, the extrapolation of actual swim counts to total estimates warrants some consideration (Burns, unpubl). Assumptions concerning the distribution of chinook in the river at the time of the survey are the basis for expanding these counts to estimate total escapement (T. Fields, 230 Underwood St., Duncan, B.C. V9L-3X3, pers comm.). In 1991, it became apparent that during high water flow conditions in early fall, expansions based on the swim survey results overestimated total escapement (Nagtegaal et al. 1994b, 1994c). The results of the 1992 swim surveys support the hypothesis that during low water flow conditions in late fall, expansions based on swim survey results underestimate the number of spawners. Low flow conditions lead to underestimation of spawners because the distribution of fish in the river is affected by flow. Generally, in low water years, not as many fish make it to the traditional spawning areas above Skutz Falls. Expansion of swim surveys conducted in the upper area alone tend to underestimate the number of fish. Conversely, during high water years most of the fish make it above Skutz Falls so the expansion factor tends to overestimate the number of fish.

Flow rate was average during September to November (Fig. 5). Based on the carcass tagging data most chinook spawned in the upper river section in 1999. Since each swim survey count was expanded by the same factor, no consideration was made with regards to the distribution of chinook in the river. The adult escapement estimate for upper river spawners based on the expanded swim count $(1,641)$ was much lower compared to the fence count extrapolation. An insufficient number of swims were made during the season, particularly during the peak and end of the run, to make any appropriate estimates of chinook escapement.

Since we did not have the opportunity to directly assess catch estimation procedures developed by the Cowichan Tribes Aboriginal Fisheries Management unit, no comments could be made regarding the methodologies used. The 1999 estimate of 233 adult chinook was a considerable decrease over last year. The prevailing fishing conditions were considered to be very good during September/October based on information provided by CTAF staff. According to CTAF staff, the spear fishery catch was likely between 600-800 adult chinook. In past, independent observer estimates of adult chinook catch have been 2 to 3.5 times the amount estimated by the CTAF unit. No independent estimates were made in 1999.

## BIOLOGICAL DATA

Significant differences were only noted in the adipose mark rate for females between the random broodstock sample recorded by the hatchery staff and the data collected from the spawning grounds by our field staff. The incidence of adipose-clipped female chinook sampled on the spawning ground was $6.3 \%$ and in the hatchery chinook broodstock sample was $3.1 \%$. Significant differences were also noted in the size frequency distribution of adult male chinook between hatchery and spawning ground samples ( $\mathrm{D}_{\text {obs }}<\mathrm{D}_{\text {alpha }}$; Kolmogorov-Smirnov, Zar 1984). This may in a large part be due to the proportionately fewer smaller male carcasses that were recovered in the spawning ground sample. This is likely due to the fact that these lighter carcasses were washed downstream and were not available for biosampling on the spawning ground as readily as the larger and heavier adult carcasses.

Typically, the hatchery collects broodstock from various locations in the river and randomly samples $25 \%$ to $50 \%$ of males, females and jacks at the hatchery after the fish are spawned. In addition, all other adipose-clipped fish collected for broodstock are selectively sampled for production assessment purposes.

MARK-RECAPTURE

Fall rains that often occur during spawning cause high flows and turbid water. Carcasses are often trapped in deep pools and cannot be seen or easily recovered due to the turbid conditions. Conditions for carcass recovery were generally good in the upper river for the first half of the survey, but were particularly poor in the middle section, with high flows and cloudy water, making it difficult to tag or recover carcasses. On the first sampling trip to the middle section of the river, several hundred live spawners were observed although few carcasses tagged. Subsequent trips to this section were unproductive due to poor tag and recovery conditions. Conditions for tag and
recapture deteriorated rapidly during the last weeks of November. We were able to tag and sample approximately 13\% of the total adult chinook escapement.

Stratification by sex was necessary in order to minimize the effects of differential tagging and recovery between sexes. Some potential biases associated with tagging and recovery of carcasses were examined and it was assumed that these could significantly affect the population estimate. For whatever reason, smaller adult carcasses were much less available for tagging and therefore the estimate for males was considered to be low. If we assume that the fence count extrapolation was the preferred method of estimating escapement, then the stratified Petersen estimates based on carcass mark-recapture underestimated escapement by at least $25 \%$. If we assumed the sex ratio to be approximately $50 / 50$ and simply doubled the mark-recapture estimate for females then the result would be approximately 4100 adults. If we then expanded that by $25 \%$ to adjust for the numbers that spawned in the middle section of the river, the total estimated adult escapement would be approximately 5100.

SEAL PREDATION

Although seal predation was not directly assessed in this
study, it is worthwhile to examine the impact seals have on chinook in Cowichan Bay. In 1988, the number of seals gradually increased from a low of 30 in April to a peak of about 100 in December. According to Olesiuk et al. (1990) harbour seals consume an estimated 9 tonnes of salmon annually in Cowichan Bay. An estimated 23\% (Sept.) to $48 \%$ (Nov.) of the harbour seals' diet in Cowichan Bay was comprised of salmon (Bigg et al. 1990). Based on these data, consumption of chinook salmon could potentially range from 100 to 500 adults. These data were collected in 1988 when low flows in the Cowichan River persisted until the end of October. Predation likely increases the longer chinook salmon remain in the estuary waiting for high water to allow upstream migration. Predation on chinook in 1999 was estimated to be approximately 300 and somewhat less than the past few years even though low flow conditions occurred in September and October. DFO charter patrol observations indicated that fewer numbers of seals and sea lions were present in Cowichan Bay.

ESCAPEMENT

Escapement (natural spawners and total return) estimates for 1999 were primarily based on fence data since this was the preferred enumeration technique. The number of natural spawners was determined to be the fence count minus broodstock removals above the fence. If we also add an estimate for migration before and after the fence was in place then the total number of spawners is estimated to be approx. 4,500 (Table 20).

Total return of adult chinook to the Cowichan River was determined to be equal to the sum of the fence count and the number of adults removed below the fence by the hatchery for broodstock and in the Native spear fishery. If we also add an estimate for migration before and after the fence was in place then the total return is estimated to be approx. 6,392 (Table 20). If we include a seal predation estimate of 300, then it is probable that the total return of chinook in 1999 was closer to 6,700 adults.

Adult chinook escapements have fluctuated from a low of 1200 in $1986 / 87$ to over 16,000 in 1995, the largest escapement recorded for the past 40 years (Fig. 6). In recent years chinook escapement has increased substantially and came close to or exceeded the escapement goal of 12,500 in 1995 and 1996. This escapement trend may in part be due to substantial increases in hatchery production (Fig. 7) and a reduction in commercial and sport fleet effort. Natural production as well as enhanced contribution to the escapement has increased Fig. 8). However, for the last two years the number of spawners has again dropped well below the escapement goal.

Returns of jack chinook to the Cowichan River were lower than average in 1999. If we use the fence count by year and look at the average jack to adult ratio from 1988-1998 (excluding 1990, 1993-94 when the jack return exceeded the adult count), we find that the jack count was approximately $66 \%$ of the adult fence count. This year the ratio was only $33.8 \%$ or 1,291 jacks. One explanation for this poor return may be the reduced hatchery production for the 1997 brood year (Fig. 7). This may also indicate poorer returns of 3 and 4 year olds in 2000 and 2001.

## ACKNOWLEDGEMENTS

We would like to thank Phillip Joe, Dave Key, Dave Burton, Kevin Timothy, Kyle Fairbanks, Ian Sinclair, Grant MacPherson, John Paige, Steve Alphonse and Kevin Pellet for their involvement in the implementation of the enumeration fence, collection of migration and biological data. We thank W. Jansen and E. Teskey, Fisheries and Oceans Canada Fishery Officers stationed in Duncan, for their helpful
assistance. We thank the Cowichan Tribes Fisheries Management Unit, in particular Wayne Paige, Jed and Doug August, and Wayne Paige Jr. for their cooperation and assistance in acquiring Native food fishery data and swim survey results. We thank Doug Millerd, manager of the Cowichan hatchery, for providing broodstock capture and biosampling data. We thank the conscientious sport fishers who returned the Ketchum tags from the chinook they caught in the Cowichan River. We thank the City of Duncan for allowing us to use their access road to the counting fence site and granting us storage space, power and water from their pumphouse facility. We thank C. Harlow, from Fisheries and Oceans Canada, B. Hollingshead, the Regional Water Manager for British Columbia, and A. Jezierski from Fletcher Challenge Ltd. for coordinating the water release management plan for the Cowichan River.

| 1997 | 125 | 1485 |  |
| 1998 | 1659 |  |  |

${ }^{1}$ Barry Cordecedo (Salmon Enhancement Program) provided numbers on broodstock collection from 1981-1987. The brood stock numbers provided included jacks, but no reliable records were kept. It was estimated that about 10-15 jacks were collected per year, except in the first few years in the Cowichan River. These estimates were subtacted from the broodstock numbers provided to give an estimate of the number of adult chinook removed from the system.
${ }^{2}$ In addition, 284 males were removed for broodstock but later returned to the river.

Table 7. Summary of chinook broodstock age data ${ }^{1}$, 1999.

| Age | Males | Females | Total |
| :---: | :---: | :---: | :---: |
| 3 | 39 | 67 | 106 |
| 4 | 16 | 60 | 76 |
| 5 | 1 | 4 | 5 |
| Total: | 56 | 131 | 18 |

1 Cowichan Hatchery release strategies for chinook:
Upper Cowichan (Late): raised to pre-smolt size (5-6gm) prior to release approx. 3 km below the weir in May.
Upper Cowichan (Early): raised to fry ( 3 gm ) prior to release approx. 3 km below the weir in early April.
Cowichan Lake Pen: raised to pre-smolt size (5-6gm) prior to release just above the weir in May.
Hatchery (Late): raised to pre-smolt size ( $5-6 \mathrm{gm}$ ) prior to release at the hatchery in May.
Seapen: raised to smolt size $(6+g m)$ prior to release from the netpens in Cowichan Bay in early June.

Table 14. Summary of chinook carcass mark-recapture data from the Cowichan River, 1999.

| 1999 |  |  |  |  |

${ }^{1}$ For 1989 to the present, the number of natural spawners is calculated as the number of adults recorded at the fence minus the adults removed for broodstock above the fence.
${ }^{2}$ Total broodstock removed.
${ }^{3}$ Includes 2000 adult chinook estimated to have passed by the fence during the period of high water
${ }^{4}$ Includes the fence count and an estimate of the numbers of fish that entered the river prior to and after the fence was in place.

## Fig. 1 Cowichan River Survey Areas:

```
Swim survey locations were:
    1 - Bird House pool
    2 - Road pool
    3 - Train trestle (mile 70.2)
    4 - Old pick-up site
    5 - Maple tree
    6 - Three Firs pool
    7 - Skutz Falls
    8 - Marie Canyon
    9 - Bible Camp
1 0 ~ - ~ C o w i c h a n ~ s i d e ~ c h a n n e l
    11 - Sandy pool
    12 - Sewer
    13 - JC pool
```

## Swim survey areas:

Bird House (1) to Three Firs pool (6) represents the Upper survey section.

Marie Canyon (8) to enumeration fence (A) represents the Middle survey section.

A - refers to the adult enumeration fence
Tag recovery locations:
Locations numbered 1 to 45 are in the upper river section, those numbered 46 to 83 are in the middle river section.

## Fig. 2 River Management Zones for Native Food Fishery

```
A-Cliffs to Silver bridge
    B-Silver bridge to JC's place
    C-Quamichan to Black creek
D-Powerline to Elliot's barn
E-Elliot's barn to Brian's pool
F-Brian's pool to Clem Clem and
    part of Koksilah
G-Clem Clem to mouth
H-North side to Four plex
I-Four plex to Meriner's
    slough
J-Meriner's slough to mouth
```

Fig 3. Daily fence count of adult and jack chinook, water depth and temperature, 1999.

Fig. 6. Adult chinook escapement estimates for the Cowichan River, 1953-99.

Percent Contribution

Fig. 8. Natural and enhanced contribution to escapement, Cowichan River, 1982-99.

[^0]:    ${ }^{1}$ Includes chinook caught in the native spear fishery and the inriver gillnet fishery.
    ${ }^{2}$ Since 1988 data collected by Cowichan Tribes River Management unit. Prior to 1988, data were collected by the local Fishery Officers.
    ${ }^{3}$ Estimates for jack chinook were not provided in 1997 and 1998.

[^1]:    ${ }^{1}$ Based on hatchery field records.

[^2]:    ${ }^{1}$ Data from random biosample of hatchery chinook broodstock.

[^3]:    ${ }^{1}$ Random sample subset of total broodstock collected (does not include selected mark only sample).

[^4]:    ${ }^{1}$ Cowichan Hatchery release strategies for chinook:
    Upper Cowichan (Late): raised to pre-smolt size ( $5-6 \mathrm{gm}$ ) prior to release approx. 3 km below the weir in May. Upper Cowichan (Early): raised to fry (3 gm) prior to release approx. 3 km below the weir in early April. Cowichan Lake Pen: raised to pre-smolt size ( $5-6 \mathrm{gm}$ ) prior to release just above the weir in May.
    Hatchery (Late): raised to pre-smolt size ( $5-6 \mathrm{gm}$ ) prior to release at the hatchery in May.
    Seapen: raised to smolt size ( $6+\mathrm{gm}$ ) prior to release from the netpens in Cowichan Bay in early June.
