Canadian Manuscript Report of Fisheries and Aquatic Sciences No. 2566

## Canadian Manuscript Report of Fisheries and Aquatic Sciences

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-900 in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551.

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport manuscrit canadien des sciences halieutiques et aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques ques qui constituent une contribution aux connaissances actuelles, mais qui traitent de problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports manuscrits sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annual des publications scientifiques et techniques du Ministère.

Les numéros 1 à 900 de cette série ont été publiés à titre de manuscrits (série biologique) de l'Office de biologie du Canada, et après le changement de la désignation de cet organisme par décret du Parlement, en 1937, ont été classés comme manuscrits (série biologique) de l'Office des recherches sur les pêcheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de rapports manuscrits de l'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

Les rapports manuscrits sont produits a l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

## ABSTRACT

Baxter, B.E., C.Y. Stephens and B.L. Nass. 2001. Adult and juvenile coho salmon enumeration and coded-wire tag recovery analysis for Zolzap Creek, BC, 1998. Can. Manuscr. Rep. Fish. Aquat. Sci. 2566: viii +44 p.

Adult and juvenile coho migrations were monitored at Zolzap Creek, British Columbia, as part of the 1998-1999 Nisga'a Aboriginal Fisheries Strategy. The 1998 season is the seventh year of continuous operation of the Zolzap Creek. This report includes seven year summaries of the most pertinent data. Smolt trapping was conducted from 28 April to 23 June 1998 using an instream wire-mesh fence. A total of 15,937 coho smolts were captured during the trapping period, and an unknown number migrated out during periods when the fence was not operational. Of those captured, 13,950 were released with coded-wire tags. Migration timing, mean length and weight at age, and age composition are presented.

Adult coho escapement was monitored using an instream fence and carcass surveys. The counting fence was operational between 31 August and 19 November. A total of 967 adult coho were counted at the fence. Adipose-clip rate was $22.0 \%$ for adult coho. Age and length characteristics of adult males and females are presented.

Canadian and US commercial harvests were examined using coded-wire tag recovery data obtained from the Mark-Recovery Program and the Alaskan Department of Fish and Game (ADF\&G) mark tag and age lab online database. Total commercial exploitation rate on Zolzap Creek coho in 1998 was $46.0 \%$ ( $0.0 \%$ Canadian, $46.0 \%$ US). Of the total commercial catch of Zolzap Creek coho, Canadian catch accounted for $0.0 \%$ and the US catch accounted for an estimated $100 \%$. Harvests occurred over a wide area ranging from S.E. Alaska to the US Northern Outside Statistical Area in Alaska (northwest of Juneau, AK). Due to concerns over declining coho stocks, the Canadian fishery was shut down for coho harvests this year. No CWT returns were received from the Canadian fisheries for Zolzap Creek in 1998. US harvests of Zolzap coho in Alaska were largest in the Southern Inside Statistical Area for the net fishery and the Central Outside Statistical Area for the troll fishery. Total survival was $2.9 \%$ and smolt-tospawner survival was $1.6 \%$.

## RÉSUMÉ

Baxter, B.E., C.Y. Stephens and B.L. Nass. 2001. Adult and juvenile coho salmon enumeration and coded-wire tag recovery analysis for Zolzap Creek, BC, 1998. Can. Manuscr. Rep. Fish. Aquat. Sci. 2566 : viii +44 p.

Les migrations de saumons coho, adultes et jeunes, ont été mesurées au ruisseau Zolzap en Colombie-Britannique, dans le cadre de la Stratégie des pêcheries autochtones des Nisga'a en 1998-1999. L'änée 1998 marque la 7ième saison d'opération continue des barrières en fil métallique du ruisseau Zolzap. Ce rapport contient 7 ans de sommaires des données les plus intéressantes. Le piégeage des saumoneaux prit place entre le 28 avril et le 23 juin 1998 à l'aide d'une barrière en fil métallique installée dans le ruisseau. En tout, 15,937 saumoneaux coho ont été capturés pendant la période de piégeage tandis qu'un nombre inconnu a migré quand la barrière n'était pas opérationelle. Sur l'ensemble des saumoneaux capturés, 13,950 ont été remis à l'eau avec une marque magnétique codée. La période de migration, la longueur moyenne, le poids et lạ composition selon l'âge sont présentées.

La remonte de saumons coho adultes a été surveillée grâce à une barrière installée dans le ruisseau et à l'observation des carcasses. La barrière de comptage fut opérationelle entre le 31 . août et le 19 novembre. Un total de 967 saumons coho adultes ont été dénombrés à la barrière. Le taux d'ablation de la nageoire adipeuse était de $22.0 \%$ pour les saumons coho adultes. Nous présentons les caractéristiques d'âge et de longueur pour les mâles et les femelles adultes.

Les récoltes commerciales canadiennes et américaines ont été examinées grâce aux données de récupération des marques magnétiques codées provenant du Programme de marquage-récupération et en direct de la base de données du Département de Pêche et Chasse de l'Alaska. En 1998 le taux total d'exploitation commerciale de saumon coho au ruisseau Zolzap fut évalué à $46.0 \%$ ( $0.0 \%$ pour le Canada, $46.0 \%$ pour les États-Unis). Sur le total de prises commerciales de saumon coho au ruisseau Zolzap, le Canada en comptait 0.0\% et les États-Unis, une estimation de $100 \%$. Les récoltes couvraient un vaste secteur, $s^{\prime}$ étendant à partir du sud-est de l'Alaska jusqu'à la zone statistique nord extérieure de l'Alaska aux États-Unis (au nord-ouest de Juneau, AK). Étant donné les souçis concernant le déclin des stock de coho la pêche canadienne pour récoltes de coho fut cancellée cette année. Nous n'avons reçu aucune donnée de récupération des marques magnétiques codées des pêches canadiennes au ruisseau Zolzap pour l'année 1998. Les saumons coho du Zolzap récoltés par les États-Unis en Alaska furent plus nombreux dans la zone statistique sud intérieure pour la pêche au filet, et, dans la zone statistique centrale extérieure pour la pêche à la traîne. Le taux total de survie fut $2.9 \%$ tandis que pour les saumoneaux/géniteurs le taux de survie fut $1.6 \%$.

## INTRODUCTION

As part of an agreement between the Nisga'a Tribal Council and the Canadian Government, an Interim Measures Program (IMP) was established for fisheries research in the Nisga'a Traditional Territory, British Columbia. One component of this large research initiative focused on the assessment of juvenile and adult coho populations in tributaries to the Nass River. Juvenile and adult coho enumeration studies have been conducted on Zolzap Creek since 1992 (Nass 1996a; Nass 1996b; Nass and English 1994; Nass 1996c; Nass 1997a; Nass 1997b; Nass 1999; Nass and Frith 1999). This report presents results for studies conducted at Zolzap Creek in 1998.

The objectives of the research were to:

1. Enumerate migrating juvenile coho and estimate escapement;
2. Document the timing, size, and age distribution of migrating coho;
3. Mark coho smolts with coded-wire tags (CWT) to enable the determination of oceanic harvest rates;
4. Monitor the escapement for marked (CWT) adult coho, and determine oceanic exploitation and survival rates; and
5. Collect water temperature and level data for future examination of the relationships between physical environmental factors and coho smolt migration timing, and between adult escapement and smolt production.

Achievement of these objectives involved the construction and operation of instream, semi-permanent, panel fences located approximately 0.5 km upstream of the mouth of Zolzap Creek.

## STUDY STREAM

Zolzap Creek is a tributary to the Nass River, located in northwestern British Columbia (Fig. 1 and 2). Zolzap Creek flows for 6 km in a northwesterly direction between Nisga'a Lava Bed Memorial Park and the Kitimat Mountain Range to its confluence with the Nass River, 5 km downstream of Gitwinksihlkw. The main channel of the creek is regularly interrupted by beaver dams and $\log$ jams. The substrate is highly variable and ranges between silty particulate to granite cobble, and coarse pumice. Major flow contributions come from Lava Creek ( 3 km in length) which flows from the lava beds and numerous small creeks that flow from the steep alpine. Intermittent flows of water from the Nass River and Vedder Creek are possible during flooding periods. The mouth of Zolzap Creek enters a side channel to the Nass River known as Zolzap Slough. The lower 0.5 km of Zolzap Creek regularly becomes inundated when water levels on the Nass River are high. Zolzap Creek supports many species of salmonids including
coho (Oncorhynchus kisutch), pink (O. gorbuscha), chum (O. keta), sockeye (O. nerka), rainbow (O. mykiss), cutthroat (O. clarki), and Dolly Varden (Salvelinus malma). Non-coho species include lampreys (family Petromyzontidae), sticklebacks (family Gasterosteidae), and sculpins (family Cottidae). Coho escapement was estimated to be 1,561 in 1992 (Nass 1996b); 1,048 in 1993 (Nass 1996c); 2,536 in 1994 (Nass 1997a); 908 in 1995 (Nass 1997b); 1,039 in 1996 (Nass 1998) and 470 in 1997 (Nass and Frith 1999).

## JUVENILE COHO STUDIES

## METHODS

## Trapping Operations

An instream, semi-permanent enumeration fence was located 0.5 km upstream of the creek mouth for the capture of downstream migrating coho smolts. Fence design was based on Conlin and Tutty (1979) and minor modifications were required due to site characteristics and available materials. The fence was built in a W-pattern and spanned the entire creek bed. Three by eight foot panels constructed of 2 "x 4 "s and covered with $1 / 4$ " wire-mesh were laid on their long side in the creek bed to form the fence. Rebar of $3 / 8^{\prime \prime}$ and $1 / 2$ " diameter were used to anchor the panels to the stream bed. A second layer of panels was installed on top of the first row of panels to create a fence with a total height of six feet. Burlap sandbags and heavy duty plastic garden sheeting were used to seal the base of the panels. Two hinged panels were installed in each of the fence wings for release of excess water in the event of flooding. Plywood trap boxes with Vexar-screened windows (to allow water exchange) were anchored at each downstream apex and were connected to the fence with 8" Big-O tubing. Additional boxes were made for holding fish after processing and were designed with a small door for releasing fish. Provisions for upstream migrating adults were made by constructing a simple trap consisting of a wire-mesh panel extending out from the stream bank to one wing of the fence. Plywood was used to cover the adult trap area.

Juveniles were captured using roe-baited gee traps when the fence was inoperable due to flood conditions. During periods of low water, seining was used to supplement fence catches.

## Physical Observations

Crews monitored water temperatures, water levels, and weather daily. Crews recorded temperature to the nearest degree $\left(1^{\circ} \mathrm{C}\right)$ using a maximum-minimum thermometer and water level using staff gauges calibrated to the nearest centimeter ( 0.01 m ). A total of three staff gauges were used; two were located within 50 m of the trapping site (one upstream, one downstream of the fence) and one approximately 1 km upstream of the fence. Precipitation was recorded on a scale of zero to five with zero representing no precipitation and five being heavy precipitation.

## Fish Enumerations

Daily numbers of coho smolts captured at the fence were obtained from automatic counters on coded-wire tagging machines or by manual counts. The number of fence mortalities was added to the total count. Coho juveniles with standard lengths greater than or equal to 70 mm were identified as smolts. Coho smaller than 70 mm tended to be dark with distinct parr marks and lacked the silver colouration typical of smolts; therefore, this group consisted of presmolts and fry. All coho pre-smolts and fry, and non-coho species were counted and released downstream of the fence during sorting. Upstream migrating juveniles caught in the adult traps were counted and released upstream.

## Biosampling

A random sample of up to 25 smolts (i.e., coho greater than or equal to 70 mm ) were obtained from each day's catch. These smolts were anaesthetized and measured for fork length and weighed using an electronic scale ( 0.1 g ). Scale sampling followed the stratified method of Ketchen, described by Ricker (1975); age sample data (column X on Table 1) included nonrandom samples, and length sample data (column Y on Table 1) and the calculated age representation was based on random sampling. Crews attempted to collect at least 10 scale samples from each 5 mm size class of coho for the study period. Smolts from under-represented size classes were selected to supplement random samples. Mean length and weight data were determined by multiplying the mean length and weight data for each 5 mm bin class by the total number of length and weight samples in that bin class (factor) to come up with an average weighted length and weight for that bin class. The average length and weight for all sampled fish was determined by summing all the weighted length and weight measurements and dividing by the overall sum of the factors. Scale samples were interpreted by Birkenhead Scale Analyses, Lone Butte, BC. Secondary quality control checks were performed to ensure a reliable age designation. Scale ages are reported in Gilbert-Rich notation where freshwater age 2 coho (i.e., having survived two winters from egg deposition) have a single freshwater annulus.

Biosampling was also conducted on a sub-sample of cutthroat and steelhead trout and sockeye. Length, weight, scales and DNA tissue samples were obtained from adults and juveniles. No data or analysis is presented here, but the data can be obtained from the principal author.

## Coded-wire Tagging

Coded-wire tagging at Zolzap Creek was performed using a Mark IV tagging machine (Northwest Marine Technology Ltd., Shaw Island, WA). Smolts were anaesthetized in a MS222 bath prior to tagging. All tagged fish were adipose-fin clipped (AFC). The numbers of coho smolts tagged with each tag code and the number of smolts untagged were recorded. All tagged smolts were placed in a holding box in the stream and allowed to recover from the tagging operation before release.

Tag retention tests were conducted for each tag code. A sample of tagged coho smolts (minimum of 200 smolts) were retained in a holding box from 24 h to 96 h . Following the holding period, smolts were lightly anaesthetized and checked for the presence of a coded-wire tag using the quality control device (QCD) from the coded-wire tagging machine. Coho smolts not possessing a tag were checked a second time. The total number of tags detected for each tag group and the total number of fish tested were recorded.

## RESULTS

## Physical Observations

Water temperatures during the smolt migration period at Zolzap Creek ranged from a minimum of $6^{\circ} \mathrm{C}$ in late April to a maximum of $13^{\circ} \mathrm{C}$ in mid-June (Fig. 3A). Water level at gauge 2 ( 50 m upstream of the fence) remained steady at a gauge height of 0.3 m from the beginning of monitoring on 29 April until 23 May. Water level rose sharply to 2.1 m within 5 days following 23 May and flooded the fence during the period 28 May to 1 June. Water levels continued to fluctuate between 0.3 m and 1.4 m until the end of the spring monitoring period on 23 June. High water levels in Zolzap Creek occur when the Nass mainstem flow rises causing water to back-up into the creek. Water flow in Zolzap Creek declines to very low velocities during these flooding events.

## Fish Enumerations

The Zolzap Creek juvenile counting fence was operated from 29 April to 23 June 1998. Seining was used to supplement catches at the fence during periods of low water. In addition, approximately 25 to 30 baited gee traps were used during the flooding of the fence and for a short period after.

Coho Smolts: A total of 15,937 coho smolts were counted at the fence (Table 2). This total includes catches from seining and gee trapping. The maximum daily number of smolts captured at the fence was 1,593 and occurred on 19 May (Table A-1; Fig. 4). An unknown number of smolts moved past the trapping location during fence flooding. An additional 3,000 smolts were estimated to have left the system based on the pattern of migration. There were a total of 1,528 fry and pre-smolt coho counted and released during trapping operations and 14 mortalities (Table A-1).

Non-coho Species: Lampreys (larvae and young adults) were caught in the largest numbers followed by juvenile sockeye, Dolly Varden and chum (Table 3; Table B-1).

## Biosampling-Length. Weight, and Age

The mean fork length of age 2 smolts was 99.0 mm and the mean weight was 9.8 g (Table 1). Age 3 smolts averaged 110.7 mm and 13.8 g and age 4 smolts averaged 129.5 mm and 21.5 g. The length-frequency distribution showed substantial overlap between age 2 and age 3 coho
(Fig. 5). Age 2 smolts and age 3 smolts were most numerous in the $100-105 \mathrm{~mm}$ length class. Age 3 coho smolts were significantly larger than age 2 smolts ( t -test, $\mathrm{p}<0.05$ ). Overall, coho smolts averaged 104.1 mm in length. The calculated freshwater age structure of coho smolts was $58.3 \%$ age $2,40.5 \%$ age 3 and $1.2 \%$ age 4 (Table 1).

## Coded-wire Tagging

Mean tag retention was $99.6 \%$ (Table 4). Crews conducted ten tests for tag code 28-1621 for a total of 1,965 samples with a total of 7 tag losses.

Releases of adipose-clipped coho totalled 13,950 (Table 5; Table C-1). Crews recorded 108 mortalities associated with the tagging process. The total number of coho smolts released with coded-wire tags was 13,900 . Approximately $11 \%(1,771)$ of the captured coho smolts were released untagged during the study period and thus the mark rate of coho smolts released was 1.13 (Table 5). The total number of smolts released was 15,721 .

## ADULT COHO STUDIES

## METHODS

## Population Estimates

An aluminum conduit fence anchored to a crib-type sill was constructed at Zolzap Creek. All salmonids caught at the fence were counted and classified by sex. Sex was distinguished on the basis of length and body morphology. Previous studies at Zolzap Creek (Nass 1996b; 1996c; 1997a; 1997b; Nass and Frith 1999) have shown an absence of jacks in the escapement and, therefore, all males were classified as adults. "Jack panels" consisting of 1 " wire mesh were used to prevent the passage of small coho through the fence and were used whenever water levels and debris permitted. Each coho was tagged on the operculum with a uniquely numbered Ketchum kurl-lock tag and measured for length. During handling, fish were examined for fin clips or tags that would be associated with coded-wire tagging or mark-recapture studies taking place on the Nass River. All captured fish were released upstream of the fence.

Adult coho abundance downstream of the fence was assessed later in the migration period due to the lack of fish movement past the fence. Delayed migration was the result of persistent low water conditions in Zolzap Creek in the later fall period. During these periods of delayed fish movement, angling was conducted approximately 1 km downstream of the fence in Zolzap Slough to determine relative coho abundance. Coho were examined for sex and AFC's, and a uniquely numbered opercular tag was applied. All fish captured were released back into Zolzap Slough. Live coho were recaptured in upstream surveys and checked for operculum tags.
Carcasses were recovered on the fence and during upstream surveys. In 1998, carcasses were recovered primarily in the lower 2 km of the creek.

## Biosampling

All live coho captured at the fence were measured for postorbital-hypural length and examined for fin clips and sex. Data recorded from coho captured at the fence were used to calculate sex ratios and mean length by sex. Crews attempted to sample at least 25 coho a day for scales ( 10 scales per fish). Scale samples were sent to the Fisheries and Oceans Canada scale lab, Nanaimo, BC, for age determination. Secondary quality control checks were performed at the scale lab to ensure reliability of the age designations. Scale ages are reported in Gilbert-Rich notation where freshwater age 2 coho (i.e., having survived two winters from egg deposition) have a single freshwater annulus.

Adult returns (calculated by escapement method) and smolt production, by CWT and total populations, were calculated for each brood year where data were available. Smolt output and adult escapement was apportioned between brood years (back-calculated) using the age structure observed in the respective yearly migrations. The sum of freshwater age 2 , age 3 , and age 4 individuals equals total production for a given brood year. Age composition for smolts and adults by brood year were calculated based on the estimated production. Total survival by brood year was calculated as the age specific adult return divided by the respective smolt production. The smolt-to-spawner ratio for each brood year was calculated as the number of smolts produced divided by the number of adults in the escapement, by brood year. Similarly, the recruit-tospawner ratio for each brood year was calculated as the number of adults produced divided by the number of adults in the escapement, by brood year.

## Coded-wire Tag Recoveries

Coded-wire tagged smolts were AFC prior to release. Coho smolts at Zolzap Creek were coded-wire tagged (CWT) in the spring of 1997 (Nass and Frith 2001) during out-migration.

Escapement: Crews examined all coho captured at the fence for the presence or absence of the adipose fin. The contribution and survival of AFC coho to the escapement was determined using methods presented in Bocking et al. (1992) and modified in Nass (1997a). CWT heads were collected from fish sacrificed at the fence, fish captured at the Nass River fishwheels and Meziadin fishway, and from carcass recoveries.

Commercial and Sport Harvests: Commercial and sport catches of CWT fish are monitored by the Fisheries and Oceans Canada and various US agencies and compiled in the Mark Recovery Program (MRP). Data on CWT releases and recaptures are used to estimate the number of fish from a particular stock that have been harvested in the commercial and sport fishery, as well as determining the spatial and temporal distribution of harvests (Kuhn et al. 1988; Nass 1997a). The estimates include catch (observed catch corrected for sampling effort), expanded catch (estimated catch corrected for unmarked fish), exploitation rate (proportion of CWT coho caught in the fishery), and total return (expanded catch plus escapement).

Geographic Distribution of Harvest: Coded-wire tagged fish in the commercial catch are recorded by Canadian and US fishery Statistical Areas. To estimate number of recoveries for each Canadian area, the observed CWT catch was expanded by the mean catch sampling ratio observed in the catch region (e.g., Northern Troll $=$ Statistical Areas 1, 3, 4, and 6). Similarly, US troll catch was expanded using the catch sampling ratio by quadrant (e.g., northwest) and the net catch sampling ratios, by district.

## RESULTS

## Physical Observations

During the period that the adult fence was operational, water temperatures ranged from a maximum of $12^{\circ} \mathrm{C}$ in early September to a minimum of $3^{\circ} \mathrm{C}$ in mid November (Fig. 3B). Water level ranged from 0.2 m during base flows to 0.5 m during freshets (Fig. 3B).

## Adult Enumerations

The fence was operated continuously from 31 August to 19 November. A total of 967 adult coho salmon were counted at the fence (Table 6). Of these, 947 adults were operculum tagged and released upstream. Maximum daily migration past the fence was 290 adults on 6 October (Table D-1; Fig. 6).

Coho population assessments below the fence were conducted on 10, 11, 17, 21 October and 11,12 November. A total of 54 coho were captured using angling. All coho were sexed, opercular tagged and checked for AFC's. Of the 54 tagged coho released, none were recaptured below the fence during the surveys, and 41 (76\%) were observed at the fence. Therefore, at least 13 coho remained below the fence.

Eleven surveys were conducted upstream of the fence from 17 October to 30 November at four access locations along the creek. Upstream surveys were conducted on 17 October in areas within 1 km above the fence; 19, 21, 29 October and 3,6,30 November at Goat Creek (a tributary); 30 October and 2, 6, 10, 23, 30 November at upper Zolzap Creek. A total of 166 adult coho ( 114 live, 52 dead) were examined during upstream surveys (fence to 2 km ) and on the fence (Table 6). All but one coho had been tagged at the fence; therefore, no mark-recapture estimate was calculated.

For non-coho species captured at the fence, Dolly Varden had the greatest abundance (30), followed by chum (24), and pink (23). Cutthroat (14), sockeye (10), steelhead (4) and lamprey (1) were also captured at the fence (Table 3). Chum and pink were caught in their greatest numbers in early September and sockeye were caught mainly in early October. Cutthroat and Dolly Varden were caught mainly in mid-October. The number of chum and sockeye caught in 1998 were less than in 1997. The number of cutthroat and Dolly Varden were more than in 1997. No population estimates were derived for non-coho species.

## Biosampling-Age and Length

A total of 324 coho were sampled for scales, of which 243 were successfully aged (Table 7). Unaged samples included marine regenerates. Adult males and females had different age compositions which averaged $35.1 \%$ and $28.4 \%$ freshwater age 2 , and $64.9 \%$ and $71.6 \%$ freshwater age 3, respectively. The total age composition was $32.1 \%$ age 2 and $67.9 \%$ age 3. All aged scales were recorded as marine age 1 (i.e., having 1 marine annulus).

Mean lengths of adult males and females were $51.5 \mathrm{~cm}(\mathrm{n}=469, \mathrm{SD}=9.05)$ and 56.7 cm ( $\mathrm{n}=405, \mathrm{SD}=3.88$ ), respectively. Adult male coho were widely distributed over the range of 29 to 77 cm with a mode of 57 cm (Fig. 7). Female coho had a mode of 57 cm with a range of 43 to 68 cm . For coho sexed during processing, adult males captured at the fence $(\mathrm{n}=517)$ were more abundant than females ( $n=437$ ).

## Coded-wire Tag Recoveries

Escapement: Crews examined 963 adult coho at the fence for fin clips of which 212 were AFC ( $22 \%$; Table 8). An estimated 213 adipose-clipped adult coho returned to Zolzap Creek in 1998. In addition, of the 54 coho examined below the fence, $2(0.04 \%)$ were AFC. Of the 2 AFC coho tagged below the fence, both were observed at the fence. Smolt to spawner survival (i.e., includes natural and harvest mortality) for adult coho was estimated at $1.6 \%$.

Thirty-five (35) CWT heads were collected at Zolzap Creek. Of these recoveries, 17 were from sacrifices at the fence and 18 were from carcass recoveries. In addition, 6 coho with adipose clips were recovered at the Nass River fishwheels and 1 coho was recovered with an adipose clip at the Meziadin fishway. All the CWT recoveries from Zolzap Creek were from the 1997 release at Zolzap Creek (code 28-16-20). Of the 6 fishwheel CWT recoveries, 3 were from the 1997 release at Zolzap Creek (code 28-16-20), 1 was from the 1997 release at Ft. Babine (code 18-17-6), 1 was from the 1997 release at Toboggan Creek (code 18-11-43), and 1 was a No-Pin. The 1 CWT recovery at the Meziadin Fishway was from the 1997 release at Ft. Babine (code 18-23-8).

Commercial and Sport Harvests: Total observed Zolzap Creek coho CWT recoveries were 0 and 60 for Canadian and US (Alaska) fisheries, respectively (Table 9). Observed sport recoveries totalled zero for the Canadian fisheries and one for the Alaskan fishery. All CWT recoveries were from the 1997 release year. Northern Canadian troll catch-to-sample ratio was 0.0 , while US troll and net ratios were 2.6 and 5.4, respectively (Table 9). Estimated Zolzap Creek CWT coho catches were $0(0 \%)$ and 184 (100\%) for Canadian and US fisheries, respectively (Table 9).

Expanded Canadian and US catches were 0 and 198, respectively, for a total of 198 using the CWT mark ratio at release (i.e., MRP method) (Table 10). Expanded Canadian and US catches were zero and 899 , respectively, for a total of 899 using the adipose-clip ratio at recovery
(i.e., escapement method). Estimated total adult return for Zolzap Creek coho was 426 and 1,866 using the MRP and escapement methods, respectively (Table 10).

Of the total commercial catch of Zolzap Creek coho, Canadian fisheries accounted for 0\% and the US accounted for $100 \%$ of the total commercial catch of Zolzap Creek coho (Table 11). US troll and net fisheries accounted for $70.6 \%$ and $29.4 \%$ of the total US catch, respectively. Commercial harvest of Zolzap Creek coho occurred over a wide area ranging from S.E. Alaska to the US Northern Outside Statistical Area in Alaska (Fig. 8). Due to restricted fisheries, no Canadian harvests were reported and no CWT returns were received from the Canadian fishery. US harvests were largest in the Southern Inside Statistical Area for the net fishery (13.3\%) and the Central Outside Statistical Area for the troll fishery (27.6\%; Table 11).

Total exploitation rate (Canadian and US combined) on Zolzap Creek coho in 1998 was 46.0\% (Table 12). Total Canadian exploitation rate was $0 \%$ and total US exploitation rate was $46.0 \%$ ( $34.6 \%$ troll, $11.4 \%$ net). Total survival based on CWT returns was $2.9 \%$ (Table 12).

## DISCUSSION

Over the past seven years of monitoring, the average number of smolts estimated leaving Zolzap Creek was 31,143 (Table 12). For the same time period, the average age composition of the smolt population was $57.5 \%$ age $2,41.1 \%$ age 3 , and $1.4 \%$ age 4 .

Adult coho counted at the fence in 1998 totalled 967. After CWT sacrifices ( $\mathrm{n}=17$ ), escapement was 950 plus an undetermined number of coho that spawned below the fence. The native and sport fisheries harvested an unknown number of coho below the fence. Average escapement estimates for 1992-1998 were 1,218 (Table 12) which may result in survival rates being underestimated and the exploitation rates overestimated.

Data from 1992-1997 have indicated that there are no jacks in the Zolzap Creek escapement (Nass 1996b; 1996c; 1997a; 1997b; 1999; Nass and Frith 1999). In 1998, CWT and scale ageing data have confirmed again the absence of jacks in the population. There were 35 heads taken for CWT sampling from coho measured between 28 and 63 cm (post-orbitalhypural) and all were found to be from 1997 releases. Twelve of the samples were from coho measuring less than 35 cm . This length has been used in previous studies at other BC streams to designate jacks in the escapement and is based on CWT analysis. Both the CWT analysis and scale ageing show that coho less than 35 cm from Zolzap Creek in 1998 were marine age 1.

In Alaska, comprehensive information exists for several southeast stocks, including Hugh Smith Lake (Southern Inside Statistical Area, see Fig. 8), which has been monitored since 1982. Preliminary data for the 1998 return suggests exploitation rates of $0 \%$ Canadian and $77.3 \%$ US ( $77.3 \%$ total; Leon Shaul, Alaska Dept. of Fish and Game, Douglas, AK, pers. comm.). Southeast Alaska and Canadian fisheries accounted for approximately $100 \%$ and $0 \%$ of the commercial catch of Hugh Smith coho, respectively. The total exploitation rate on Hugh Smith coho was substantially higher than exploitation rates of 0\% Canadian and 46.0\% US (46.0\%
total) on Zolzap Creek coho in 1998. Preliminary CWT data for the 1998 return of Hugh Smith coho suggest a survival rate of $11.4 \%$ which is substantially higher than for Zolzap Creek coho at 2.9\%. Hugh Smith coho have had substantially higher survivals (1997: 8.2\%; 1996: 17.9\%; 1995: $13.7 \%$; 1994: 19.4\%; 1993: 13.0\%) compared to Zolzap coho (1997: 2.4\%; 1996: 6.6\%; 1995: $3.6 \% ; 1994: 8.9 \% ; 1993: 2.1 \%$ ) in the past five years.

Zolzap Creek CWT coho have been subjected to total exploitation rates between 46.0\% and $72.3 \%$ and have had total survival rates between $2.1 \%$ and $8.9 \%$ over the period 1993 to 1998 (Table 12). Canadian fisheries have had exploitation rates between $0 \%$ and $21.4 \%$ on Zolzap CWT coho, while US fisheries ranged between $39.2 \%$ and $54.8 \%$. Of the total commercial catch of Zolzap Creek coho, Canadian fisheries have averaged $20.1 \%$ and the US has averaged $79.9 \%$, over six years (Table 12).

Total smolt production by brood year averaged 32,658 (1990-1994) and was composed primarily of freshwater age 2 fish ( $62.7 \%$; Table 13). Adult production by brood year averaged 3,987 (1990-1994) and was $54.6 \%$ age 2 fish. Age composition at return was substantially different from that observed in the respective smolt populations and varied widely. Freshwater age 4 fish were absent from all adult escapements. Total survival by brood year of all Zolzap coho (unmarked + CWT) averaged 12.8\% (1990-1994; Table 13). Total survival of Zolzap CWT coho was substantially lower at $4.7 \%$.

The number of smolts per spawner was 9.1 for the 1994 brood year. This value is conservative as the number of smolts released was likely underestimated. The number of recruits per spawner was 0.8 for the 1994 brood year.

## ACKNOWLEDGMENTS

The cooperation of many people was essential in meeting the objectives of this study. Special thanks go to Leonard Squires for monitoring all aspects of operations as crew supervisor. Peter "Normy" Squires, Tim Angus, Carol Benson, Craig McKay, Craig Haizimsque, Kevin Small, Stuart Stephens, and Lawrence Stephens assisted in constructing and operating the fence. Karl English provided technical support. Doug Herriot of the Department of Fisheries and Oceans provided the CWT catch data from the Mark Recovery Program. Robin Tamasi provided mapping support. Funding for this project was provided by the Canadian Government as part of the Nisga'a-Canada (Aboriginal Fisheries Strategy) Contribution Agreement (CA98-139).

${ }^{b}$ Mark rate at release ( $=$ No. released / No. marked) for smolts and Total 1 (MRP method), and mark rate at return for total 2 (Escapement method).
${ }^{\text {c }}$ Expanded catch $=$ EST $*$ mark rate at release
${ }^{d}$ Total return $=$ expanded catch + escapement
${ }^{e}$ Total 1 expanded catch is calculated using the total mark rate at release and the total estimated catch for all tag codes (Table 9).
${ }^{\mathrm{f}}$ Total 2 expanded catch is calculated using the total adipose clip rate at recovery and the total estimated catch for all tag codes (Table 9).

Table 11. Estimated commercial harvest distribution of Zolzap Creek CWT coho by area and gear type, 1998. Percentage is of total commercial harvest (does not include sport recoveries).
