Canadian Manuscript Report of Fisheries and Aquatic Sciences

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in *Aquatic Sciences and Fisheries Abstracts* and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-900 in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 901-1425 were issued as Manuscript Reports of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551.

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

Rapport Manuscrit Canadien des Sciences Halieutiques et Aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui traitent de problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministére des Pêches et des Océans, e'est-à-dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications complèrwa. Le titre exact paraît au-dessus du résumés de chaque rapport. Les rapports manuscrits sont résumés dans la revue *Résumés des sciences aquatiques et halieutiques,*et ils sont classés dans l'index annuel des publications scientifiques et techniques du Ministére.

Les numéros 1 à 900 de cette série ont été publiés à titre de manuscrits (série biologique) de l'Office de biologie du Canada, et aprés le changement de la désignation de cet organisme par décret du Parlement, en 1937, ont été classés comme manuscrits (série biologique) de l'Office des recherches sur les pêcheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de rapports manuscrits de l'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

Les rapports manuscrits sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur don't le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

ABSTRACT

Chu, C. and M.A. Koops. 2007. Life history parameters of Great Lakes populations of lake trout, lake whitefish, bloater, walleye, and yellow perch. Can. Manuscr. Rep. Fish. Aquat. Sci. 2811: vi + 43 p.

Life history parameters summarize the growth, maturity and mortality of populations. This report describes the data used to calculate the life history parameters of 12 lean and 6 siscowet lake trout (*Salvelinus namaycush*), 26 lake whitefish (*Coregonus clupeaformis*), 8 bloater (*Coregonus hoyi*), 9 walleye (*Sander vitreus*) and 12 yellow perch (*Perca flavescens*) populations in the Great Lakes. Interpopulation (among populations), intrapopulation (within populations through time) and virtual population analysis results are summarized in this report. These estimates of life history parameters can be used to inform fisheries management and ecological modelling.

RÉSUMÉ

Chu, C. and M.A. Koops. 2007. Life history parameters of Great Lakes populations of lake trout, lake whitefish, bloater, walleye, and yellow perch. Can. Manuscr. Rep. Fish. Aquat. Sci. 2811: vi + 43 p.

Les paramètres du cycle biologique rendent compte de la croissance, de la maturité et de la mortalité des populations. Le présent rapport décrit les données utilisées pour calculer les paramètres du cycle biologique de 12 populations de touladi maigre, 6 populations de siscowet (touladi gras), 26 populations de grand corégone, 8 populations de cisco de fumage, 9 populations de doré jaune et 12 populations de perchaude des Grands Lacs. Les résultats des analyses interpopulationnelles (entre populations) et intrapopulationnelles (à l'intérieur des populations, dans le temps) et des analyses séquentielles des populations sont présentés dans le rapport. Ces estimations des paramètres du cycle biologique peuvent être utiles pour la gestion des pêches et la modélisation écologique.

INTRODUCTION

Life history parameters summarize the growth, maturity and mortality of populations. Particular attention has been given to estimating mortality from life history parameters because mortality directly influences the population dynamics of individual species and affects fisheries management decisions (Beverton and Holt, 1959; Pauly, 1980; Hoenig, 1983, Roff, 1984; Charnov *et al*., 1993). This report documents the data and methods used to calculate the life history parameters of several fish species and populations in the Great Lakes.

The objectives of this study were three-fold; the amalgamation of life history data for several fish species and populations within the Great Lakes into a single database, calculation of the life history parameters, and an initial examination of interpopulation (spatial, among population) differences, intrapopulation (temporal, within population) and cohort trends in the life history parameters.

METHODS

DATA SOURCES

Individual fish data consisting of the total length (cm), round weight (g), age (years), maturity (yes/no), sex (male, female or unknown), population code, population location and year sampled were gathered from several agencies throughout the Great Lakes (Table 1). Maturity data were not available for all populations. Fish that were not aged were not included in our analyses. In total, aged fish data were available for 41,394 lean and 8,815 siscowet lake trout (*Salvelinus namaycush*), 48,565 lake whitefish (*Coregonus clupeaformis*), 25,875 bloater (*Coregonus hoyi*), 18,505 walleye (*Sander vitreus*), and 73,304 yellow perch (*Perca flavescens*) in the Great Lakes basin (Table 1). Yearly data spanned the early 1980's to 2003 but were not consistently available for every year within that period (Table 2). The data were collected year-round which may produce underestimates of length at age and bias the length-based life history

parameter estimates as fish sampled in the spring will be smaller than the same fish sampled in the fall. To examine if year-round sampling underestimated length at age, year-round length at age data were compared using analysis of covariance (ANCOVA) to length at age data collected in the fall.

Locations of the populations for each species were compiled in ArcView 3.2 (ESRI, 1996) using population distinctions based on historical information, tracking and spawning data. Lean lake trout data exist for Lake Superior and Lake Huron however siscowet lake trout data were only available for populations in Lake Superior (Figure 1). Lake whitefish data were available from each Great Lake and bloater populations in lakes Michigan and Huron (Figure 2). Yellow perch data were available for all of the Great Lakes and data were available for walleye in lakes Huron, Erie and Ontario (Figure 3). Species data from Lake Ontario were not divided into different populations because population boundaries are not known for that lake (personal communication J. Dietrich, OMNR).

EXAMINING SAMPLING BIAS IN THE DATA

Much of the data used in this study came from fish caught using gillnet gangs of different mesh sizes. This sampling method is size selective with smaller meshes excluding large individuals and larger meshes excluding small individuals. Therefore growth curves fitted to these data may underestimate growth in older fish while inflating the growth rates of younger fish (Beauchamp *et al*., 2004; Taylor *et al*., 2005). ANCOVA was used to determine if mesh sizes used in this study produced biased estimates of growth rates. Lake whitefish, yellow perch and walleye data from Lake Erie were chosen to test for bias in growth estimation as these fishes were sampled extensively using a wide range of mesh sizes, 32 mm – 152 mm.

We also wanted to determine if pooling data across all mesh sizes to estimate growth for the population could negate any potential biases from individual mesh sizes. One would expect biased samples to produce two different growth curves when young (age 0 and 1) fish and old (age 7 and older) fish were included and excluded from the analysis. To examine this, we tested for differences in the mean growth curves of fish aged 0 –12 versus fish aged 2 – 7 for each species. Ages 2 – 7 was chosen since these ages are well represented in the data for each species.

LIFE HISTORY PARAMETERS

Eight life history parameters (Table 3) were calculated for each population with age, length and maturity data. For populations without maturity data (Table 1), five life history parameters (k, L_0, t_0, t_{max}, Z) were calculated. Asymptotic length, von Bertalanffy growth coefficient, age at length zero and length at age zero were calculated by fitting the length at age data to a von Bertalanffy growth function using Ford-Walford plots. Total mortality was calculated using the number of individuals caught at each age within each population and catch-curve analysis outlined in Hilborn and Walters (1992). Life history parameters were calculated for each lean lake trout, siscowet lake trout, lake whitefish, bloater, walleye and yellow perch population (interpopulation) and for the individual years within each population through time (intrapopulation).

VIRTUAL POPULATION ANALYSES

Virtual population analyses (VPA) were also used in this study. This approach differs from the inter- and intra-population analyses because it estimates the life history parameters of individual cohorts rather than the mean of the populations or means of individual years. Populations with at least 10 consecutive years of data were used for these analyses. This

included 10 populations, EWAL1, EWAL2, EYP1, EYP2, HLWFON2, HYPON2, OLWF1, OYP1, SLTSISMI7 and SLTWI2 (Table 2).

RESULTS

LENGTH AT AGE ESTIMATES FOR YEAR-ROUND VERSUS FALL SAMPLING DATA

Comparison of the length at age estimates for year-round versus fall sampling data showed no consistent pattern among populations (Figure 4) or within populations through time (Figure 5). Therefore year-round data were used for our analyses.

SAMPLING BIAS IN THE DATA

Growth curves for lake whitefish ($F_{(13,43)}$=7.052, p<0.000) and yellow perch ($F_{(13,96)}$=2.829, p=0.002) were significantly different with different mesh sizes (Figure 6). Mesh size had no effect on growth curves produced for walleye ($F_{(13,119)}$=1.729, p=0.063; Figure 6). However, to calculate the life history parameters the entire sampled population is used, that is, data from all mesh sizes are pooled together. Comparison of the mean growth curves for the two age groups, ages 0 – 12 versus ages 2 – 7, were not significantly different for lake whitefish ($F_{(1,15)}$=0.122, p=0.732), yellow perch ($F_{(1, 15)}$=0.062, p=0.807) or walleye ($F_{(1,15)}$=0.011, p=0.918) (Figure 7). This suggests that although there is sampling bias for lake whitefish and yellow perch caught with different mesh sizes, the pooled data produce growth curves representative of the mean population growth. Sampling protocols were similar for species and populations throughout the Great Lakes therefore we conclude that the extensive datasets of pooled data produce accurate estimates of the growth rates exhibited by those populations.

LIFE HISTORY PARAMETER ANALYSIS

The life history parameters calculated for the interpopulation and intrapopulation analyses are presented in Tables 4-8 with population codes corresponding to Figures 1-3. The

number of fish included in the interpopulation analyses (pooled years) does not always equal the sum of the number of fish included in the intrapopulation data (individual years) because years with less than 10 fish or only 2 age classes or only ascending catches (e.g. if fish age 1-3 were caught and there were more age 3 than age 1 or 2 fish, mortality estimates could not be calculated) were excluded from the intrapopulation analyses. Interpopulation (years of sampling data pooled for each population) results indicated that the von Bertalanffy growth coefficients (k) and total mortality rates (Z) varied the least among all of the populations (Tables 4-8). Asymptotic length (L_∞) and length at maturity (L_α) showed the greatest range among all of the species and populations.

Growth curves (averaged for all years with sampling data) are presented for each species and population in each Great Lake (Figure 8-12). In Lake Erie, the lake whitefish populations displayed similar growth curves with populations ELWF2 and ELWF3 having nearly identical growth curves. Four of the yellow perch populations had similar growth curves, the exception being the EYP1 population. The five walleye populations in Lake Erie had similar growth curves except for EWAL1 that showed lower growth than the other 4 populations from ages 1-9 (Figure 8). Lake Ontario was treated as a single population therefore no interpopulation comparisons of the growth curves could be made for that lake (Figure 9). In Lake Huron, bloater and lake trout in the main basin, HBLOON2 and HLTON2 grew faster at younger ages than populations in the other basins but had the shortest asymptotic size of the populations (Figure 10). Walleye in Lake Huron showed a similar growth pattern for all 3 populations. Lake whitefish and yellow perch in Lake Huron showed very different growth patterns among populations (Figure 11). The shape of the growth curves for lake whitefish populations in Lake Michigan were similar but the asymptotic sizes ranged from 45 cm to 65 cm (Figure 12). The

MYPMM2 populations had higher growth rates than the MYPMM1 population. Bloater populations in MM1-6 had similar growth patterns but bloater in MM6 showed higher growth rates than the other populations (Figure 12). Lake trout in Lake Superior waters off Ontario grew slower after age 5 than the other lake trout populations (Figure 13). Lake whitefish in MI7 displayed faster growth than the other 8 populations in Lake Superior. Only one yellow perch population was available for Lake Superior (Figure 14).

VIRTUAL POPULATION ANALYSES

The life history parameters varied across all of the cohorts (Table 9). Lake whitefish showed the greatest variation in life history parameters with walleye showing the least. Yellow perch had the highest mortality rates with lake whitefish cohorts in Lake Ontario having the least. The t_{max} and L_{∞} parameters of the lake trout and siscowet lake trout were likely underestimated using the VPA approach because none of the populations have been studied long enough to follow an individual cohort through to their maximum life span, i.e. greater than 20 years.

DISCUSSION

Our findings show that life history parameters vary among populations of the same species and within populations through time. These findings are consistent with recent publications documenting variation in life history parameters of fishes such as lake trout (Shuter *et al*., 1998), walleye (Lester *et al*., 2000) and yellow perch (Purchase *et al*., 2005). The spatial and temporal variation in life history traits in the Great Lakes may be due to regional factors such as climate, and local factors such as lake size. Temperature can affect the growth of fishes and may directly or indirectly affect their mortality. Variation in early growth rate and female maximum size were positively related to lake surface area and water hardness, respectively, for

yellow perch populations in Ontario (Purchase *et al*., 2005). Density-dependent growth also explained variance in intrapopulation growth parameters of bloater in Lake Michigan (Szalai *et al*., 2003).

This report documents the life history parameters calculated for 65 populations of five fishes inhabiting the Great Lakes, providing estimates for future analyses to understand variation in life history traits. These estimates of life history parameters can be used to inform fisheries management and ecological modelling.

ACKNOWLEDGEMENTS

This study was funded by the Great Lakes Fishery Commission. Many thanks to Tim Johnson, Lloyd Mohr, Bruce Morrison, Jim Bowlby, Ted Schaner, Jay Dietrich and Ken MacIntosh (all of the OMNR), Shawn Sitar (Michigan DNR), Michael Seider (Wisconsin DNR), Mark Ebener (Chippewa Ottawa Resource Authority) and David Clapp (Michigan DNR) for providing the data used in our analyses.

Table 3. Life history parameters calculated from age, length and maturity data from each species and population.

Life history parameter	Description
k	von Bertalanffy growth coefficient (yr^{-1})
L_∞	asymptotic length (cm)
t_0	age at length 0 (yr)
L_0	length at age 0 (cm)
α	age at maturity (yr)
L_α	length at maturity (cm)
Z	total mortality rate (yr^{-1})
t_{max}	maximum lifespan (yr)

Table 4. Intrapopulation life history parameter values for lake whitefish (LWF), walleye (WALL) and yellow perch (YP) populations in Lake Erie. Interpopulation (years pooled) parameters are highlighted with boxes. Population codes correspond to Figures 1-3.

Table 5. Life history parameter values for lake whitefish (LWF), smallmouth bass (SMB), walleye (WALL) and yellow perch (YP) populations in Lake Ontario. Interpopulation (years pooled) parameters are highlighted with boxes. Maturity data were not available for these populations. Population codes correspond to Figures 1-3.

* mortality estimates for interpopulation are greater than intrapopulation because the sum of young fish (age 1-3) in each age class, steepened the catch curve used to calculate mortality.

Table 7. Life history parameter values for bloater (BLO), lake whitefish (LWF) and yellow perch (YP) populations in Lake Michigan. Interpopulation (years pooled) parameters are highlighted with boxes. Maturity data were not available for all of the populations. Population codes correspond to Figures 1-3.

Table 9. Life history parameter values of cohorts used in the virtual population analyses. Population codes correspond to Figures 1-3. The last two digits in the population code represent the start of each cohort for e.g. EWAL1C90 = Walleye population 1 from Lake Erie, cohort start 1990. Age represents the ages with data for each cohort.

Species	Population	Age	k	t_o	L_∞	L_o	t_{max}	α	L_α	Z

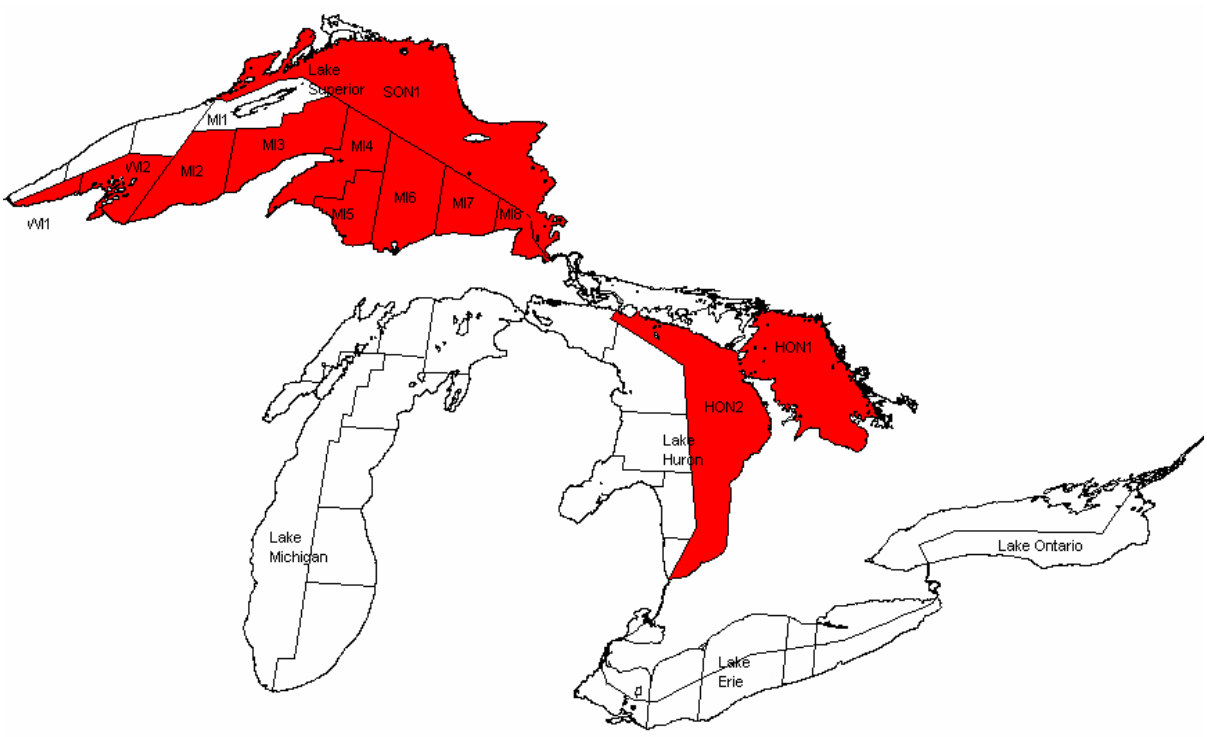

Figure 1. Extent of (a) 12 lean lake trout and (b) 6 siscowet lake trout populations used to examine life history traits in the Great Lakes basin. Black lines delineate population zones.

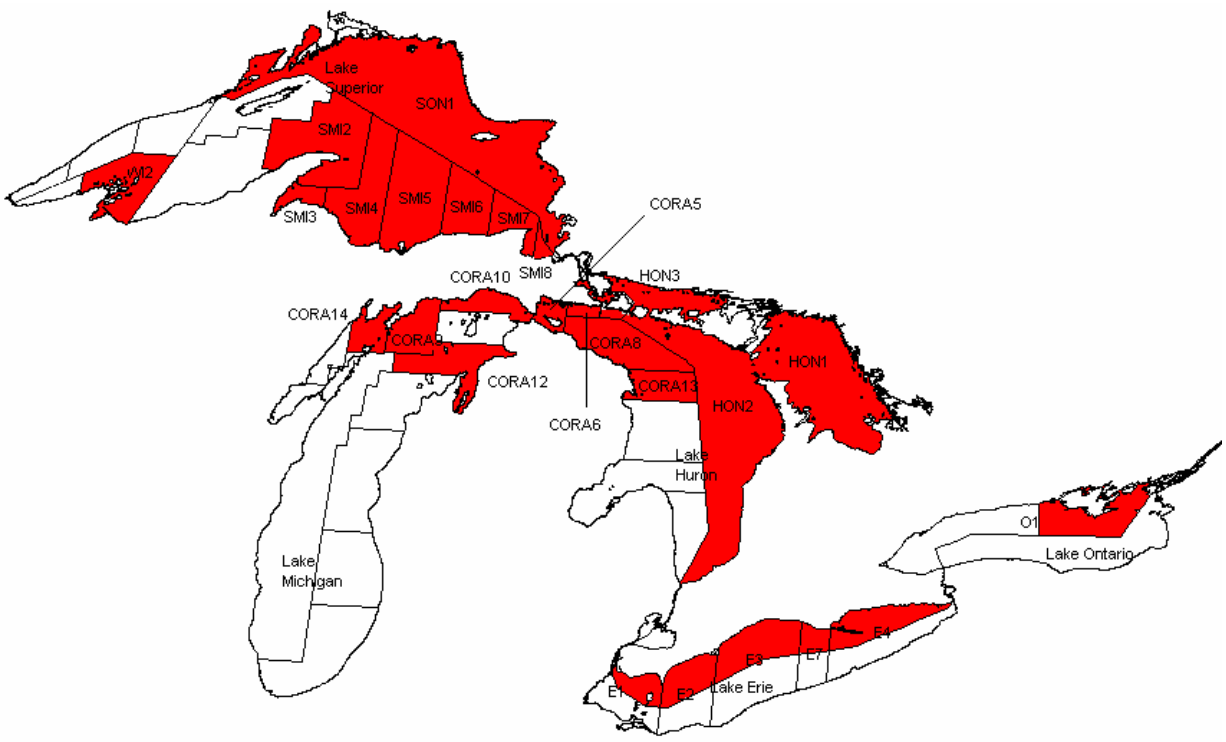
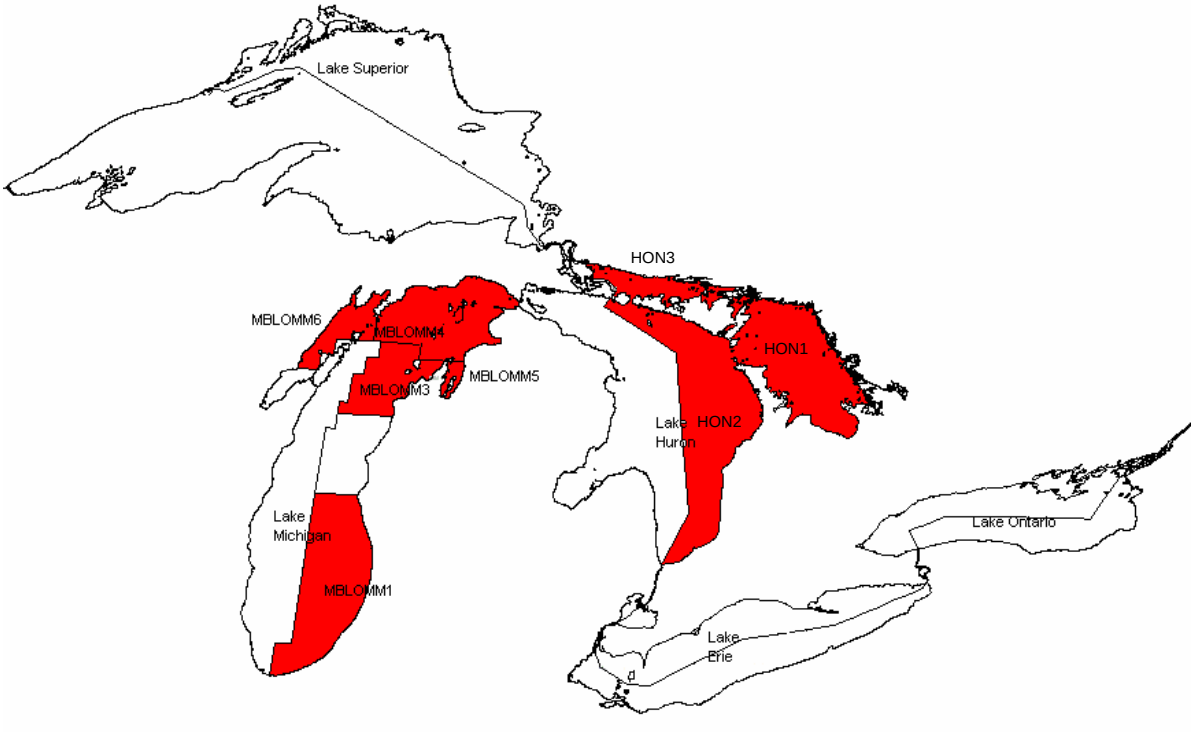
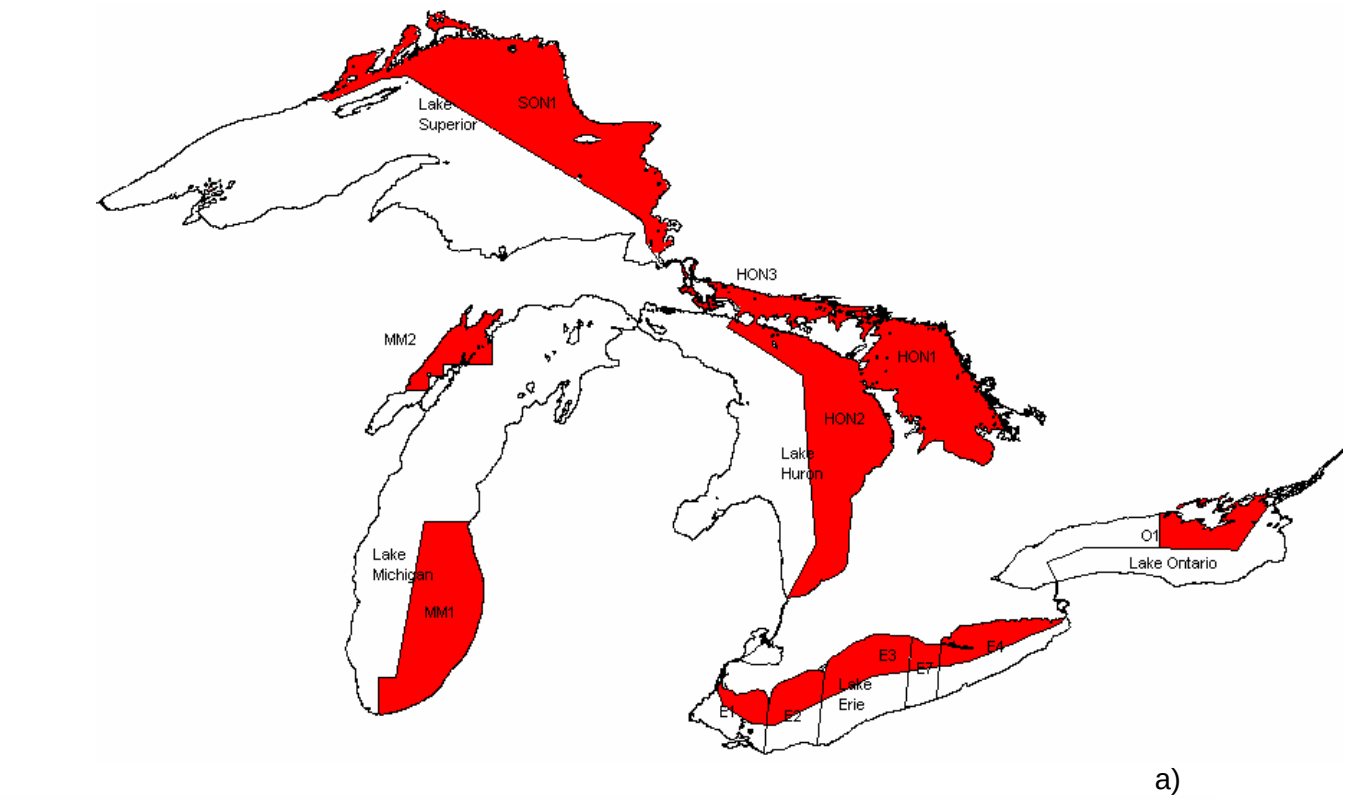


a)

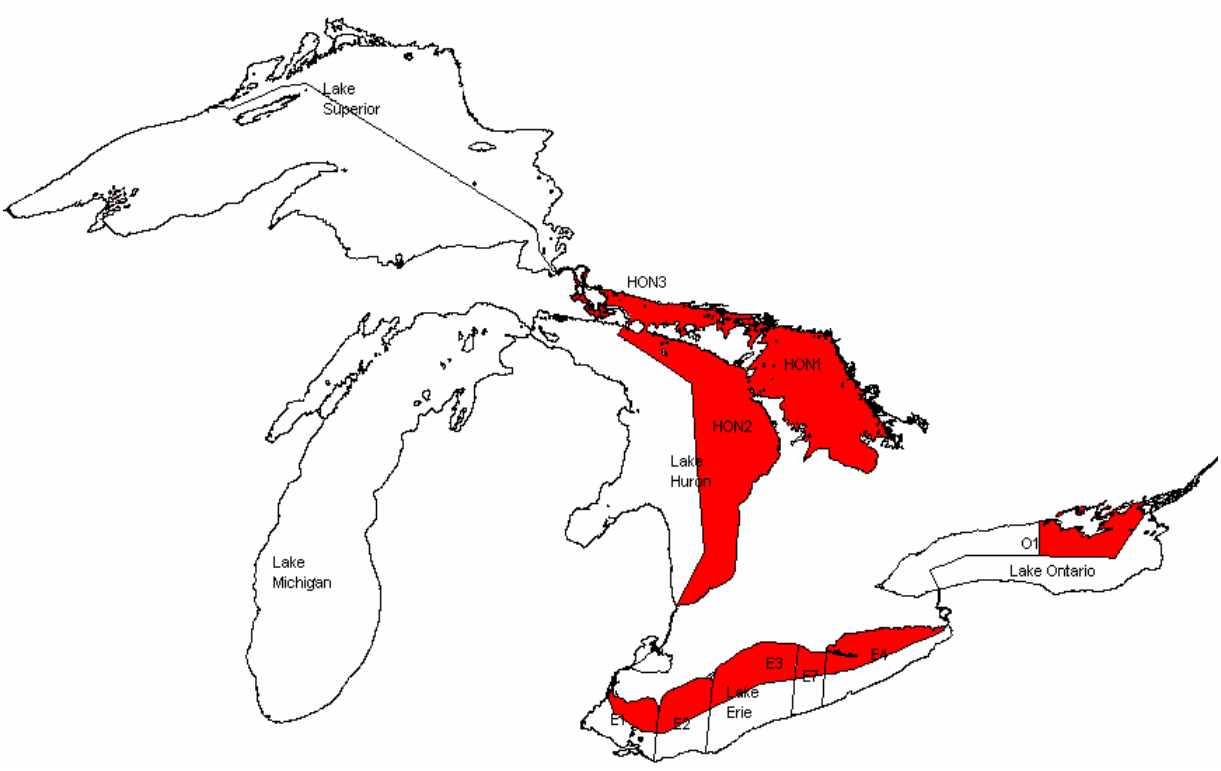


b)

Figure 2. Extent of (a) 26 lake whitefish and (b) 8 bloater populations used to examine life history traits in the Great Lakes basin. Black lines delineate population zones.



a)



b)

Figure 3. Extent of (a) 12 yellow perch and (b) 9 walleye populations used to examine life history traits in the Great Lakes basin. Black lines delineate population zones.

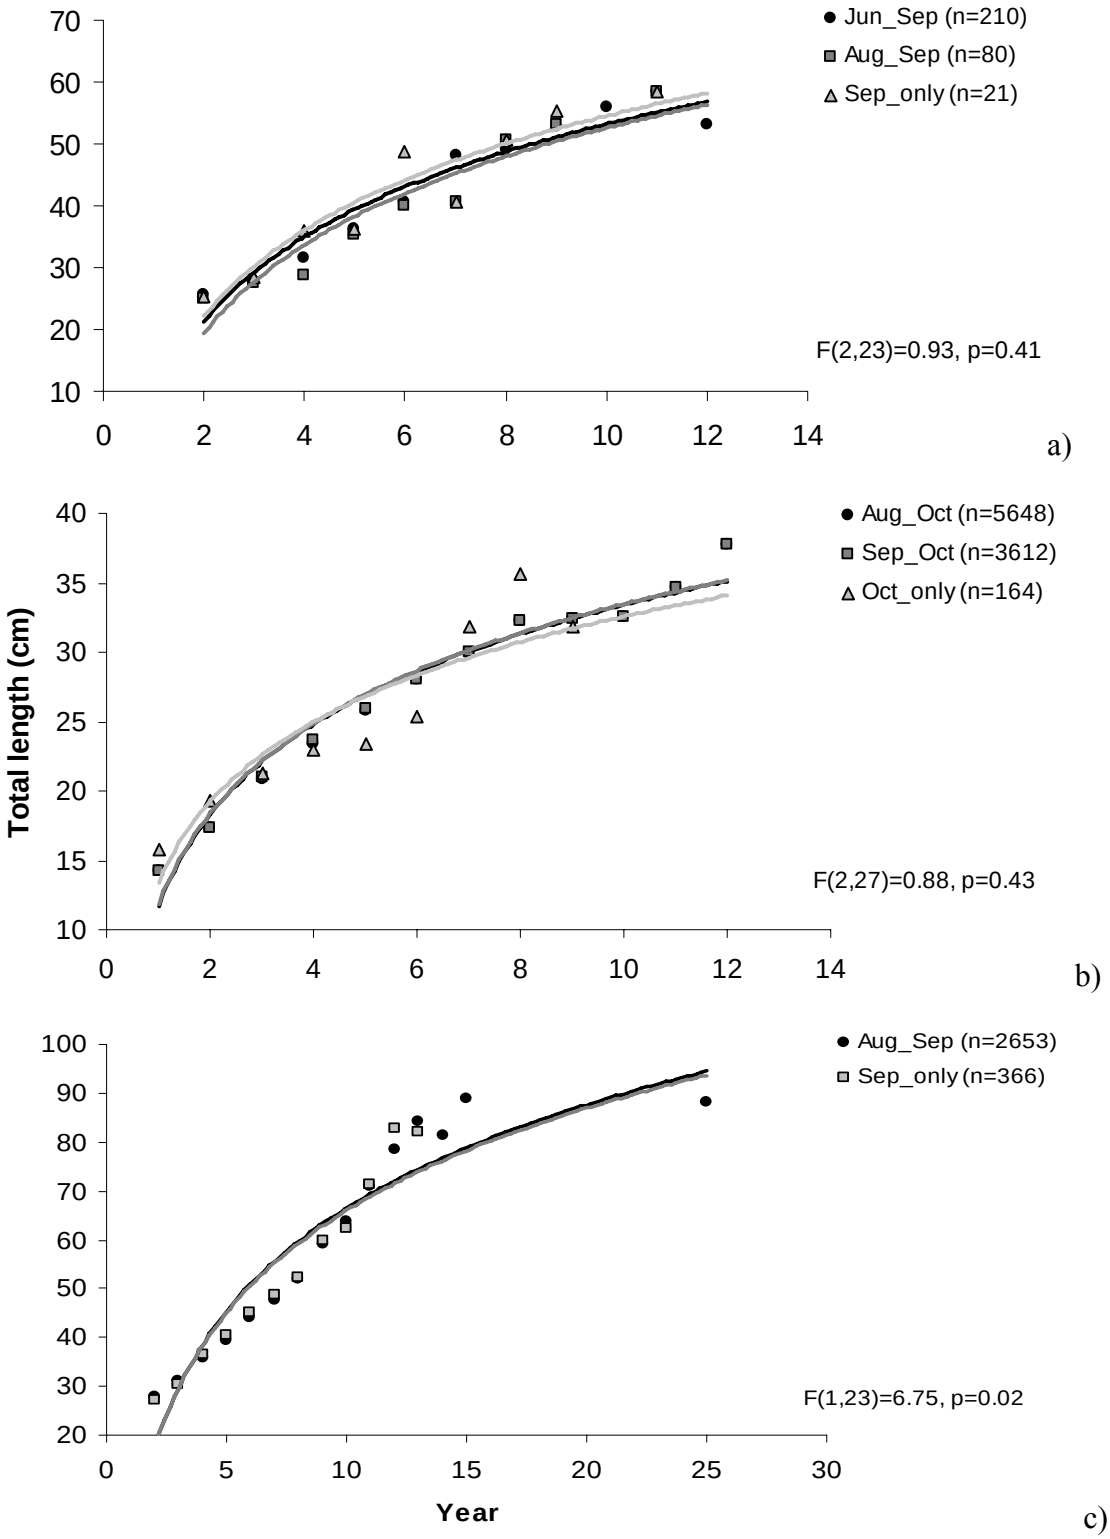


Figure 4. Comparison of the length at age relationships produced using fish collected year-round and fish collected in the summer and/or fall for three populations, (a) lake whitefish in Lake Huron (HLWFCORA13) (b) yellow perch in Lake Erie (EYP4), and (c) lake trout in Lake Michigan (SLTMI5).

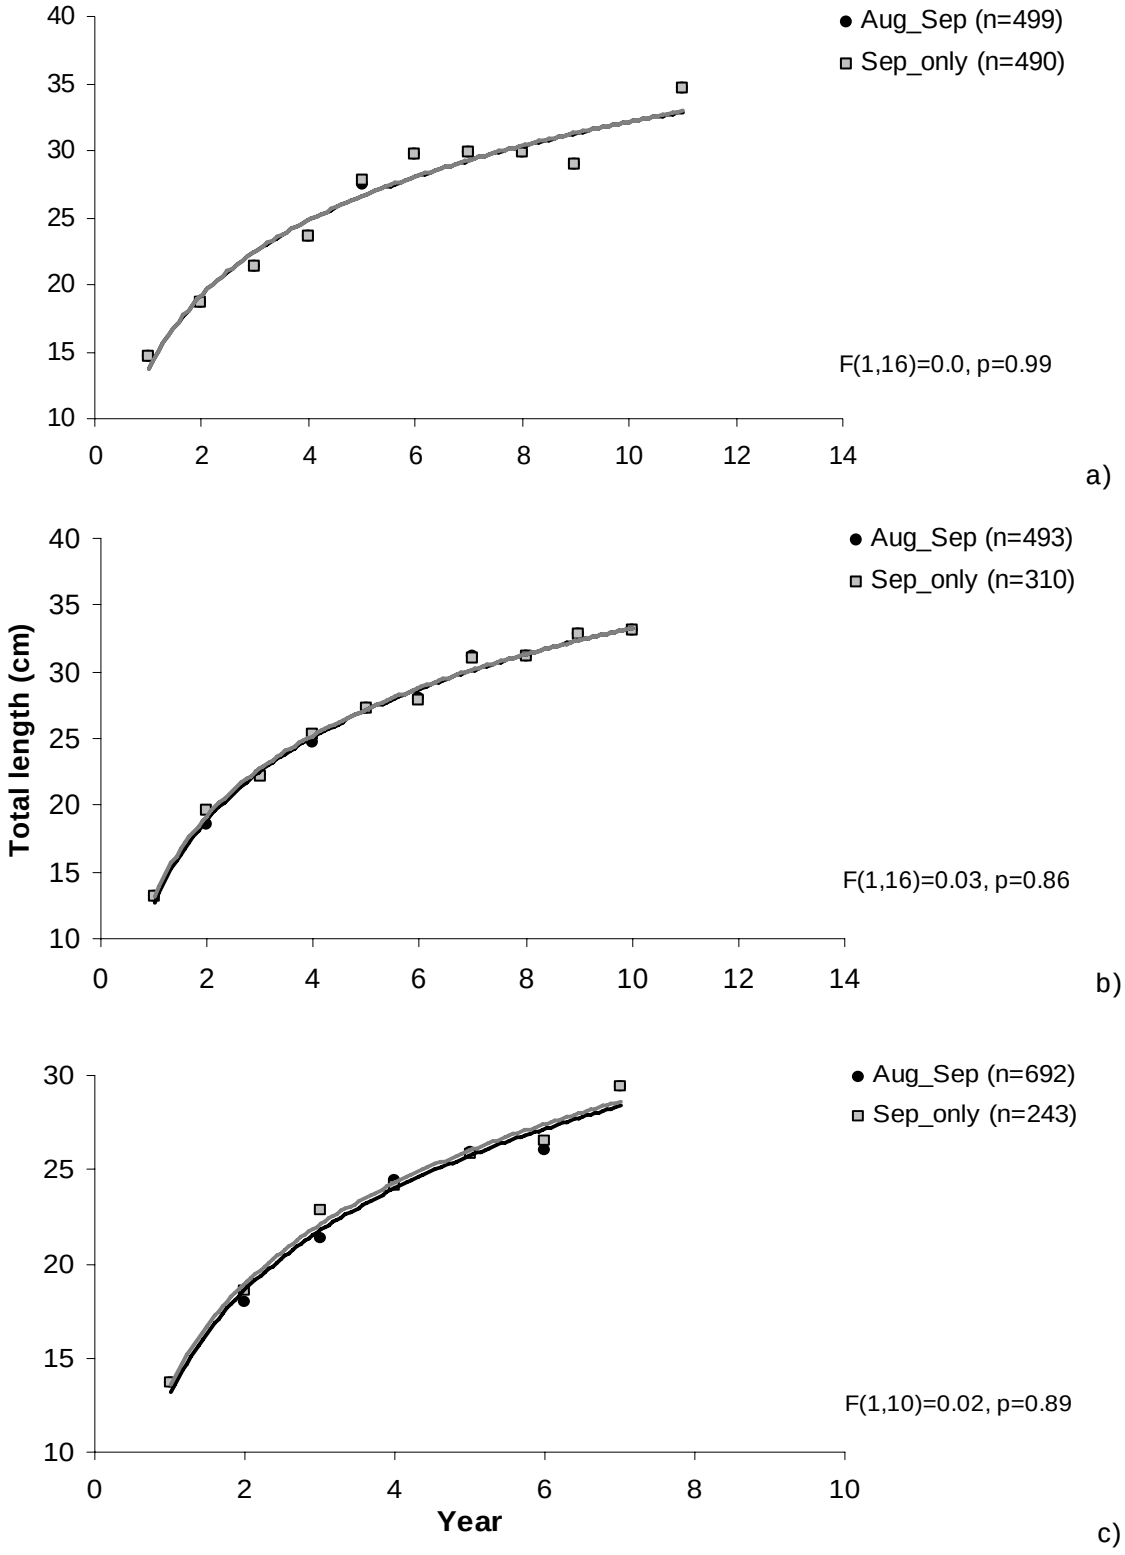

Figure 5. Comparison of the length at age relationships produced using yellow perch collected in the summer and fall within the same lake a) EYP41999, b) EYP42000 and c) EYP42001.

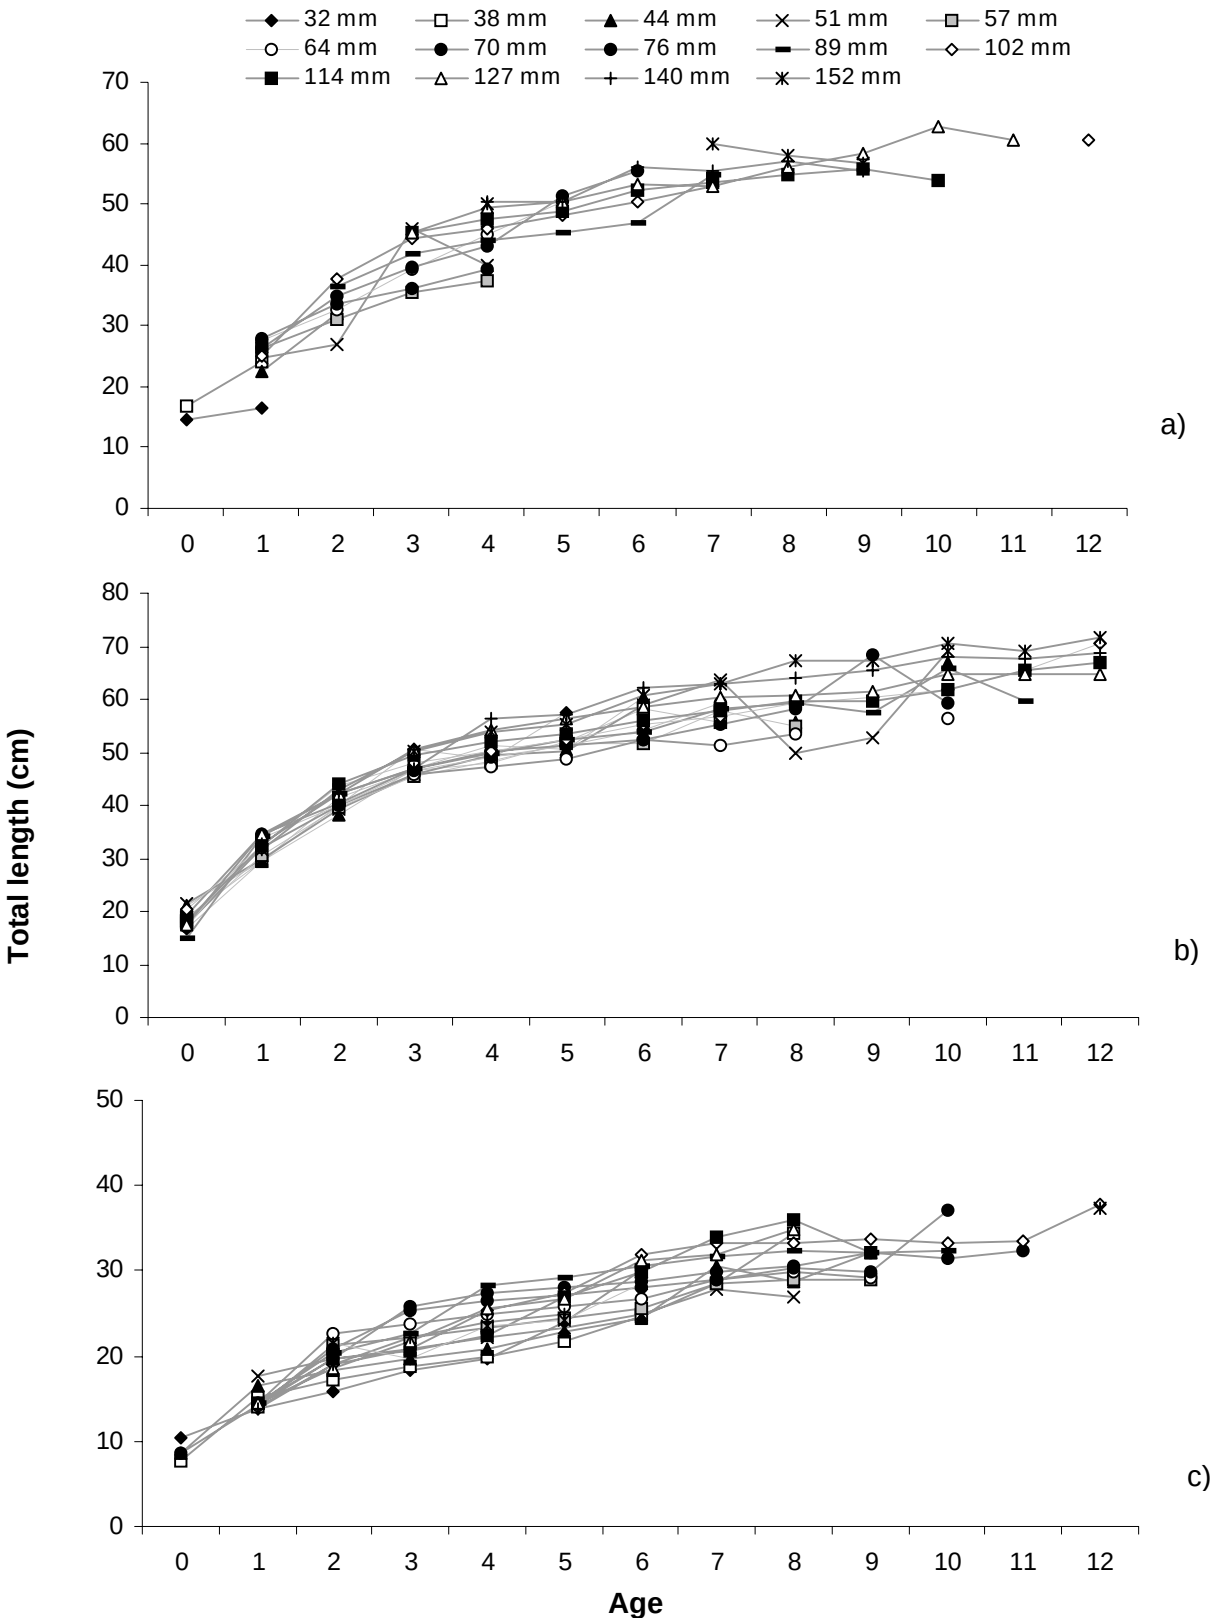

Figure 6. Length at age for a) lake whitefish, b) walleye and c) yellow perch caught using different gillnet mesh sizes in Lake Erie (all populations).

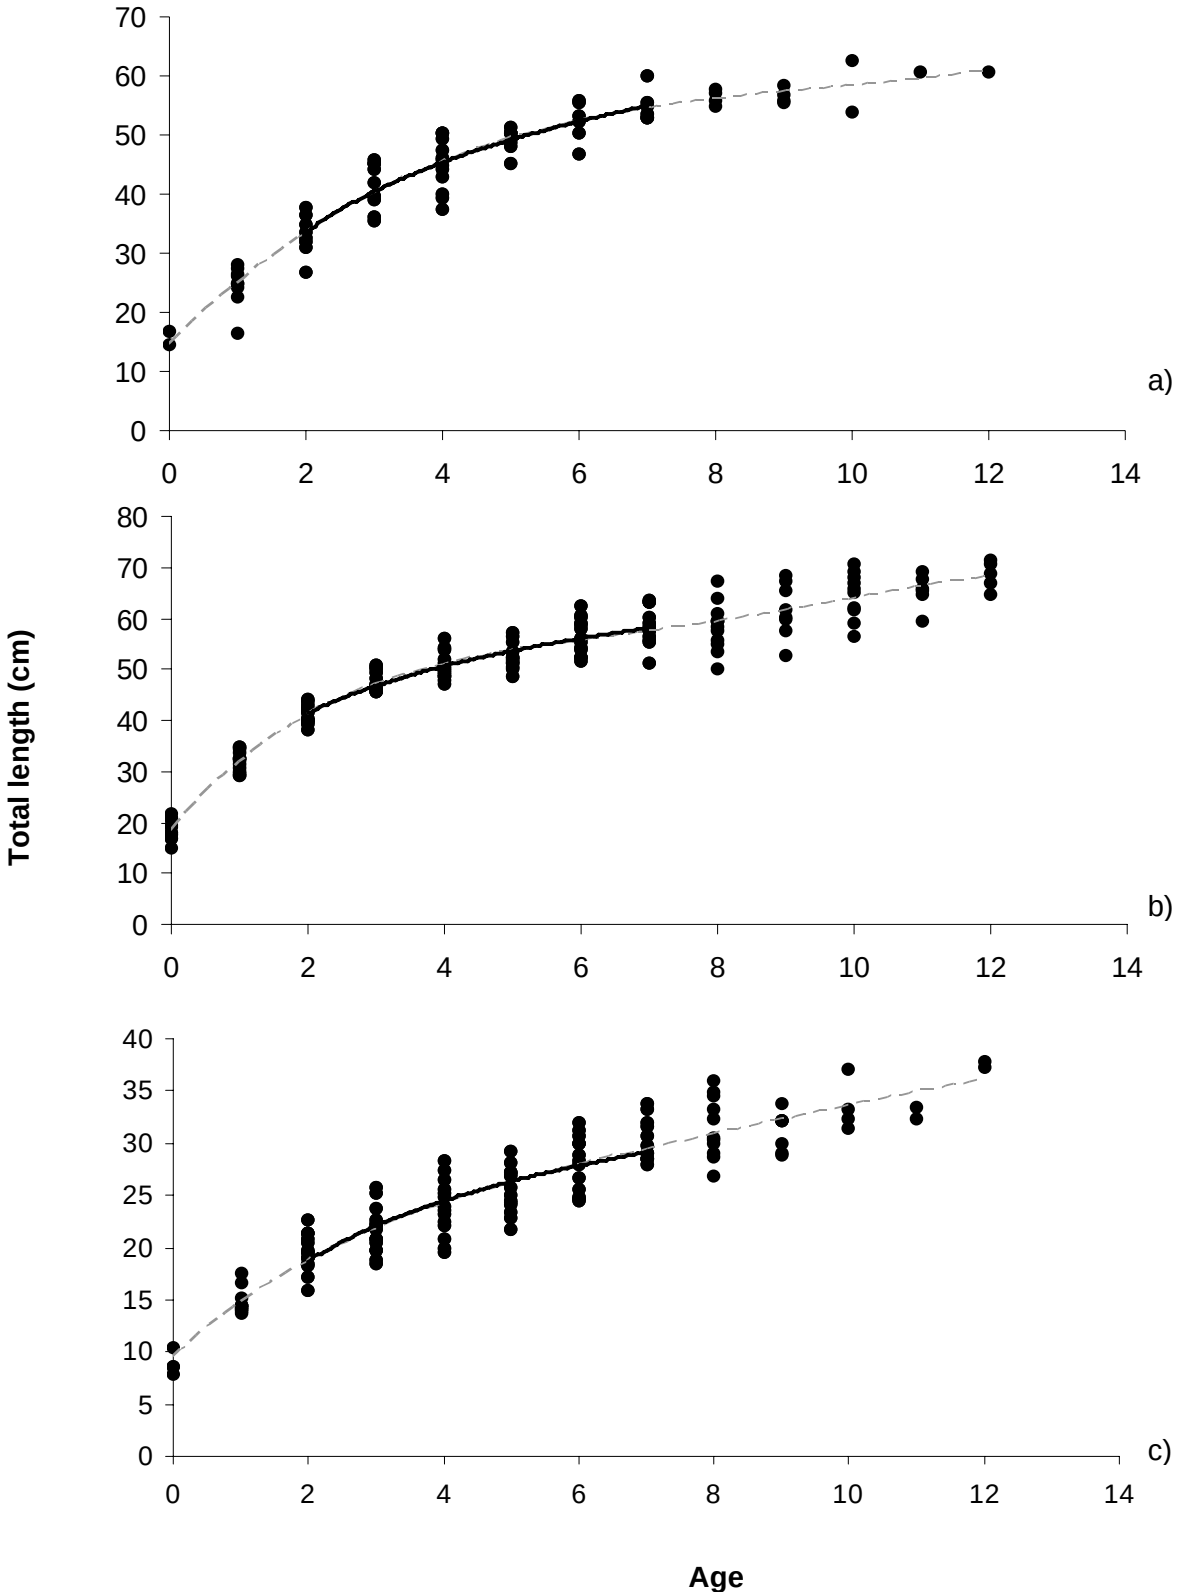

Figure 7. Growth curves for a) lake whitefish, b) walleye and c) yellow perch in Lake Erie (all populations), dashed lines represent the mean growth curve for all ages, the black line represents the growth curves for ages 2-7.

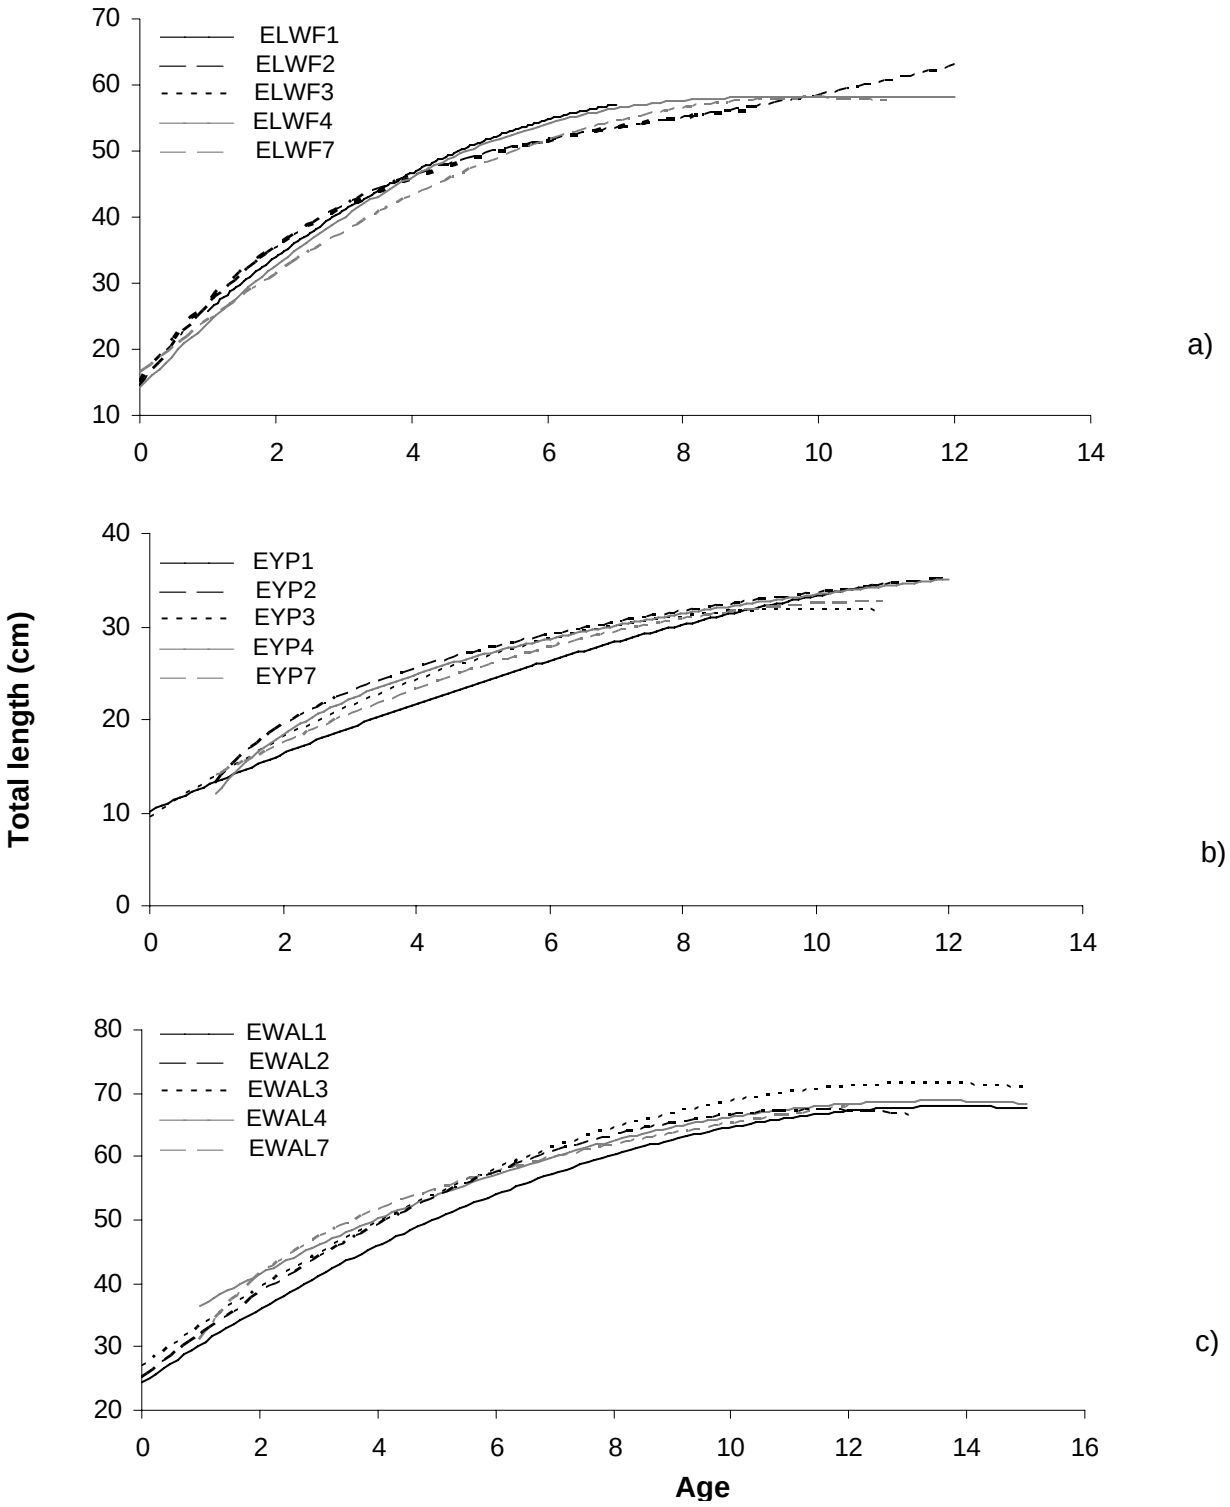

Figure 8. Growth curves for 5 populations of a) lake whitefish, b) yellow perch and c) walleye in Lake Erie. Population codes correspond to Figures 1-3.

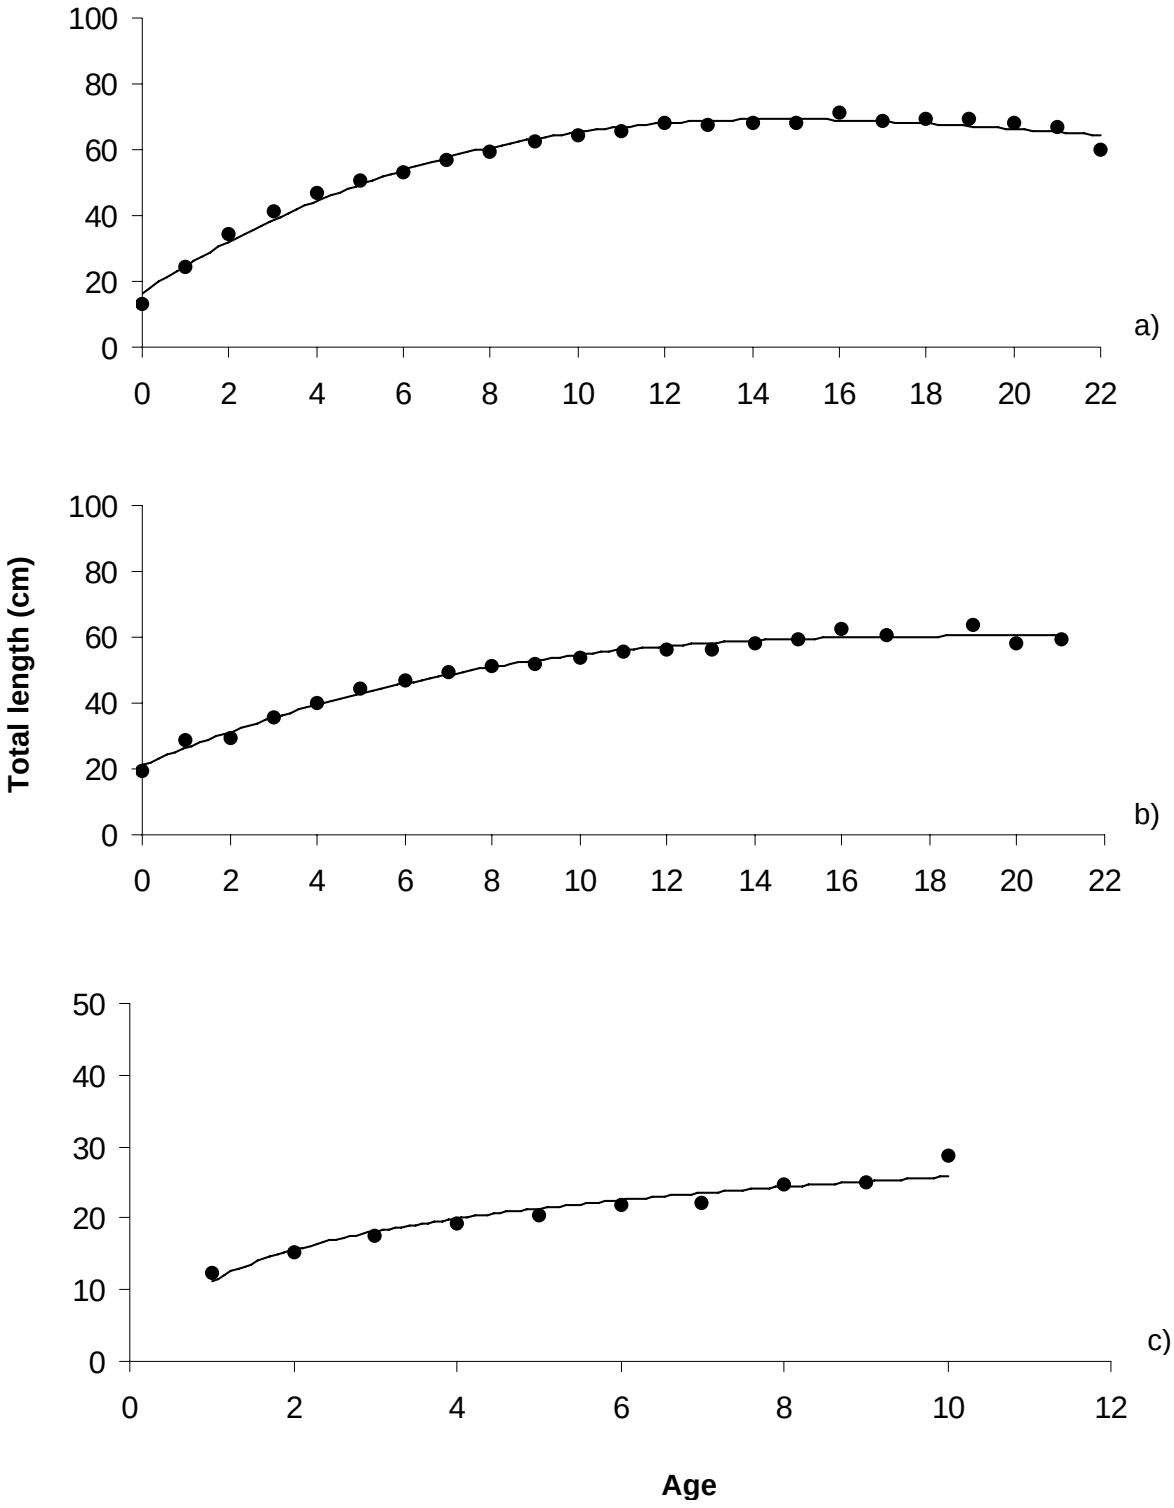

Figure 9. Growth curves for 1 population of a) walleye, b) lake whitefish and c) yellow perch in Lake Ontario. Population codes correspond to Figures 1-3.

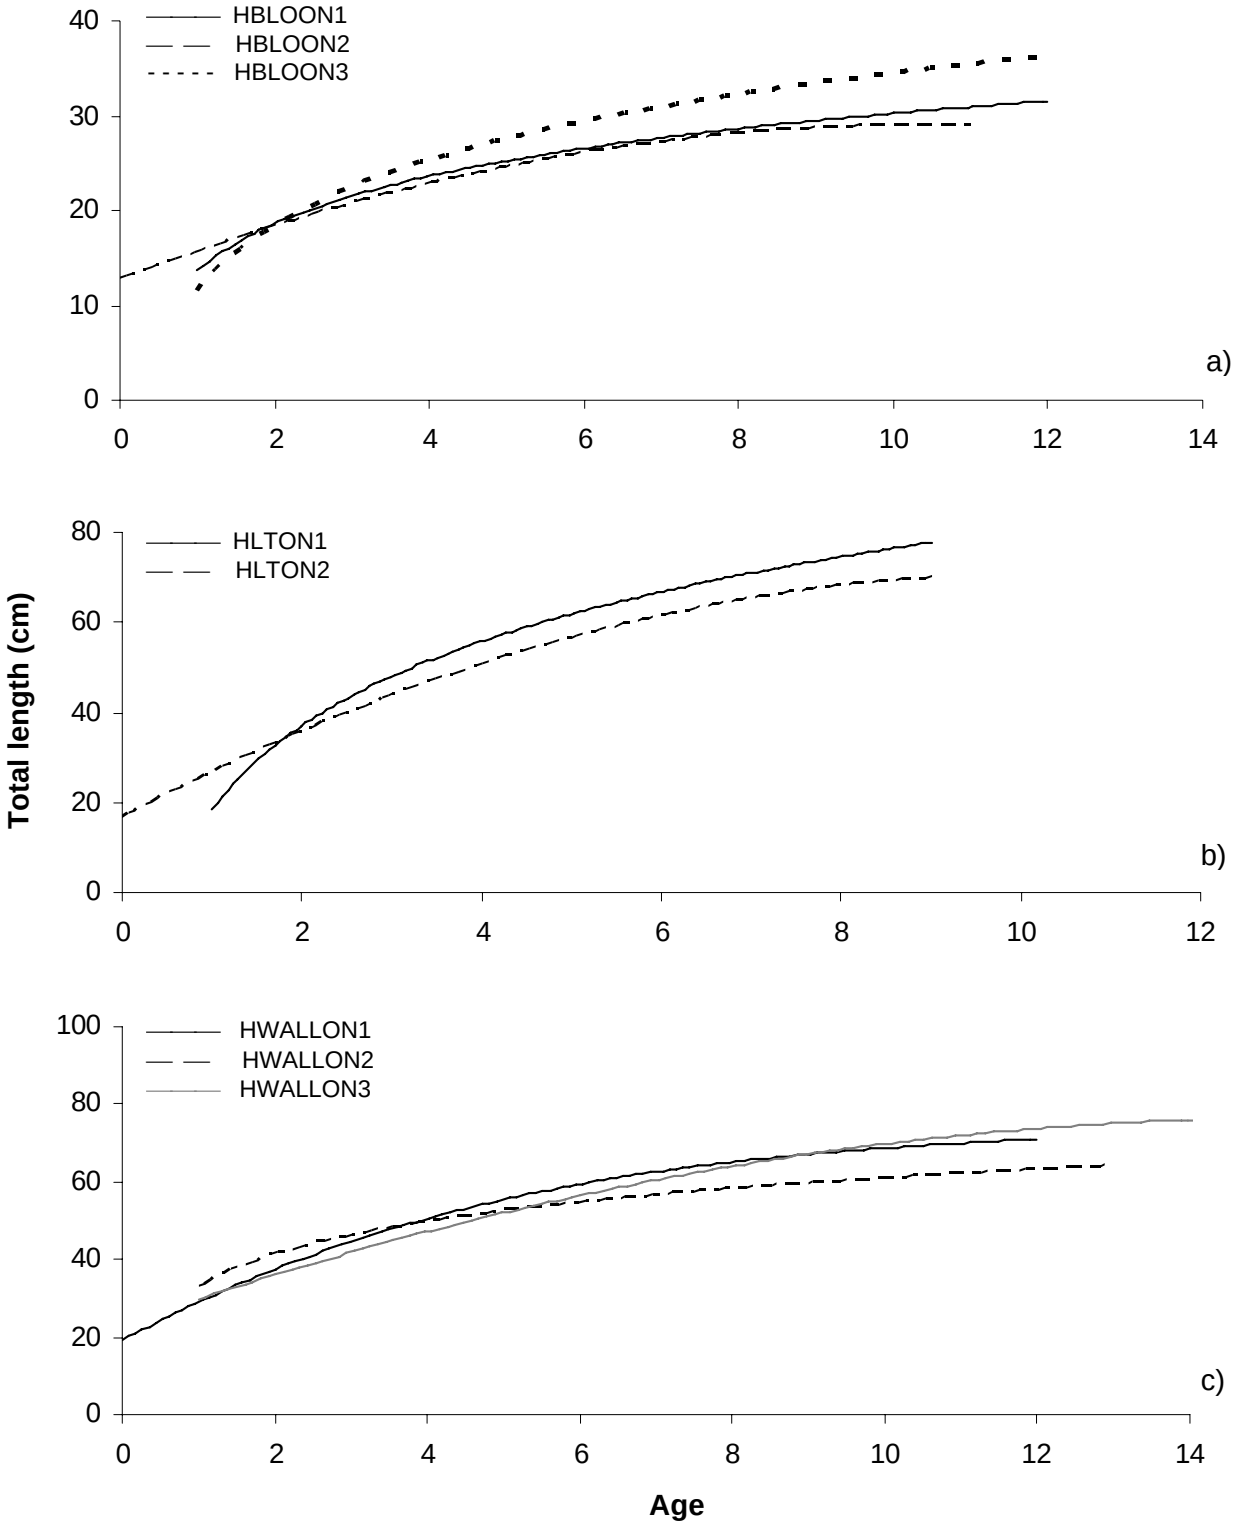

Figure 10. Growth curves for a) 3 bloater, b) 2 lean lake trout and c) 3 walleye populations in Lake Huron. Population codes correspond to Figures 1-3.

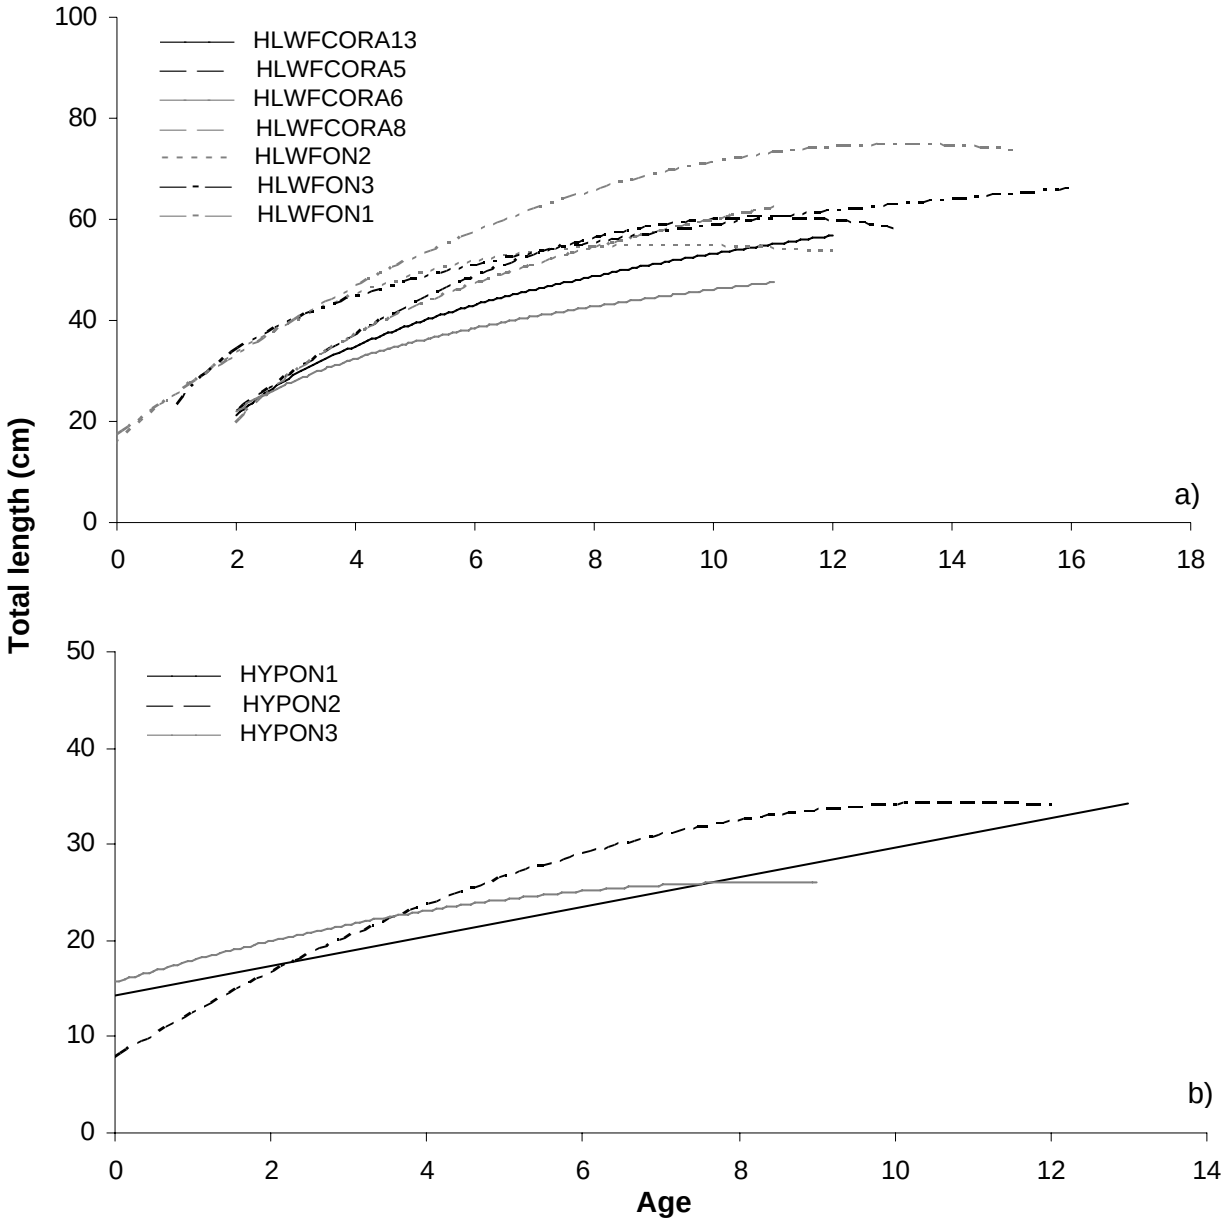

Figure 11. Growth curves for a) 7 lake whitefish and b) 3 yellow perch populations in Lake Huron. Population codes correspond to Figures 1-3.

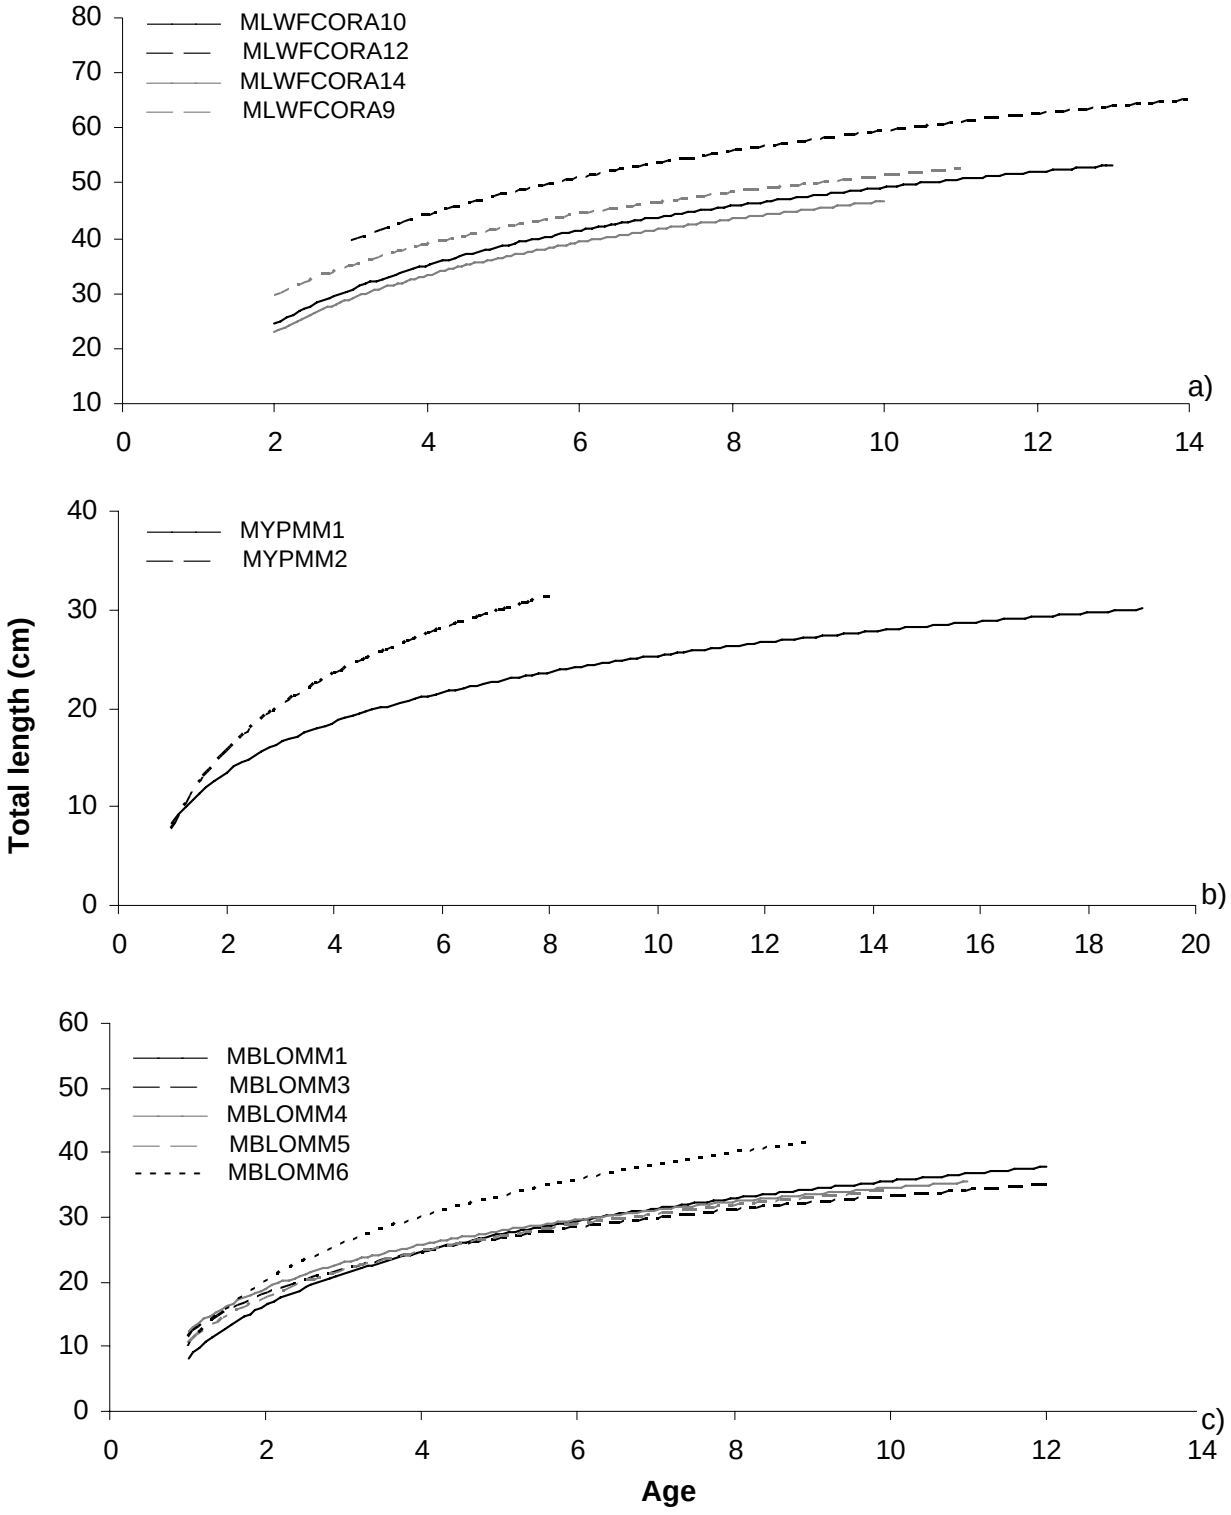

Figure 12. Growth curves for a) 4 lake whitefish, b) 2 yellow perch and c) 5 bloater populations in Lake Michigan. Population codes correspond to Figures 1-3.

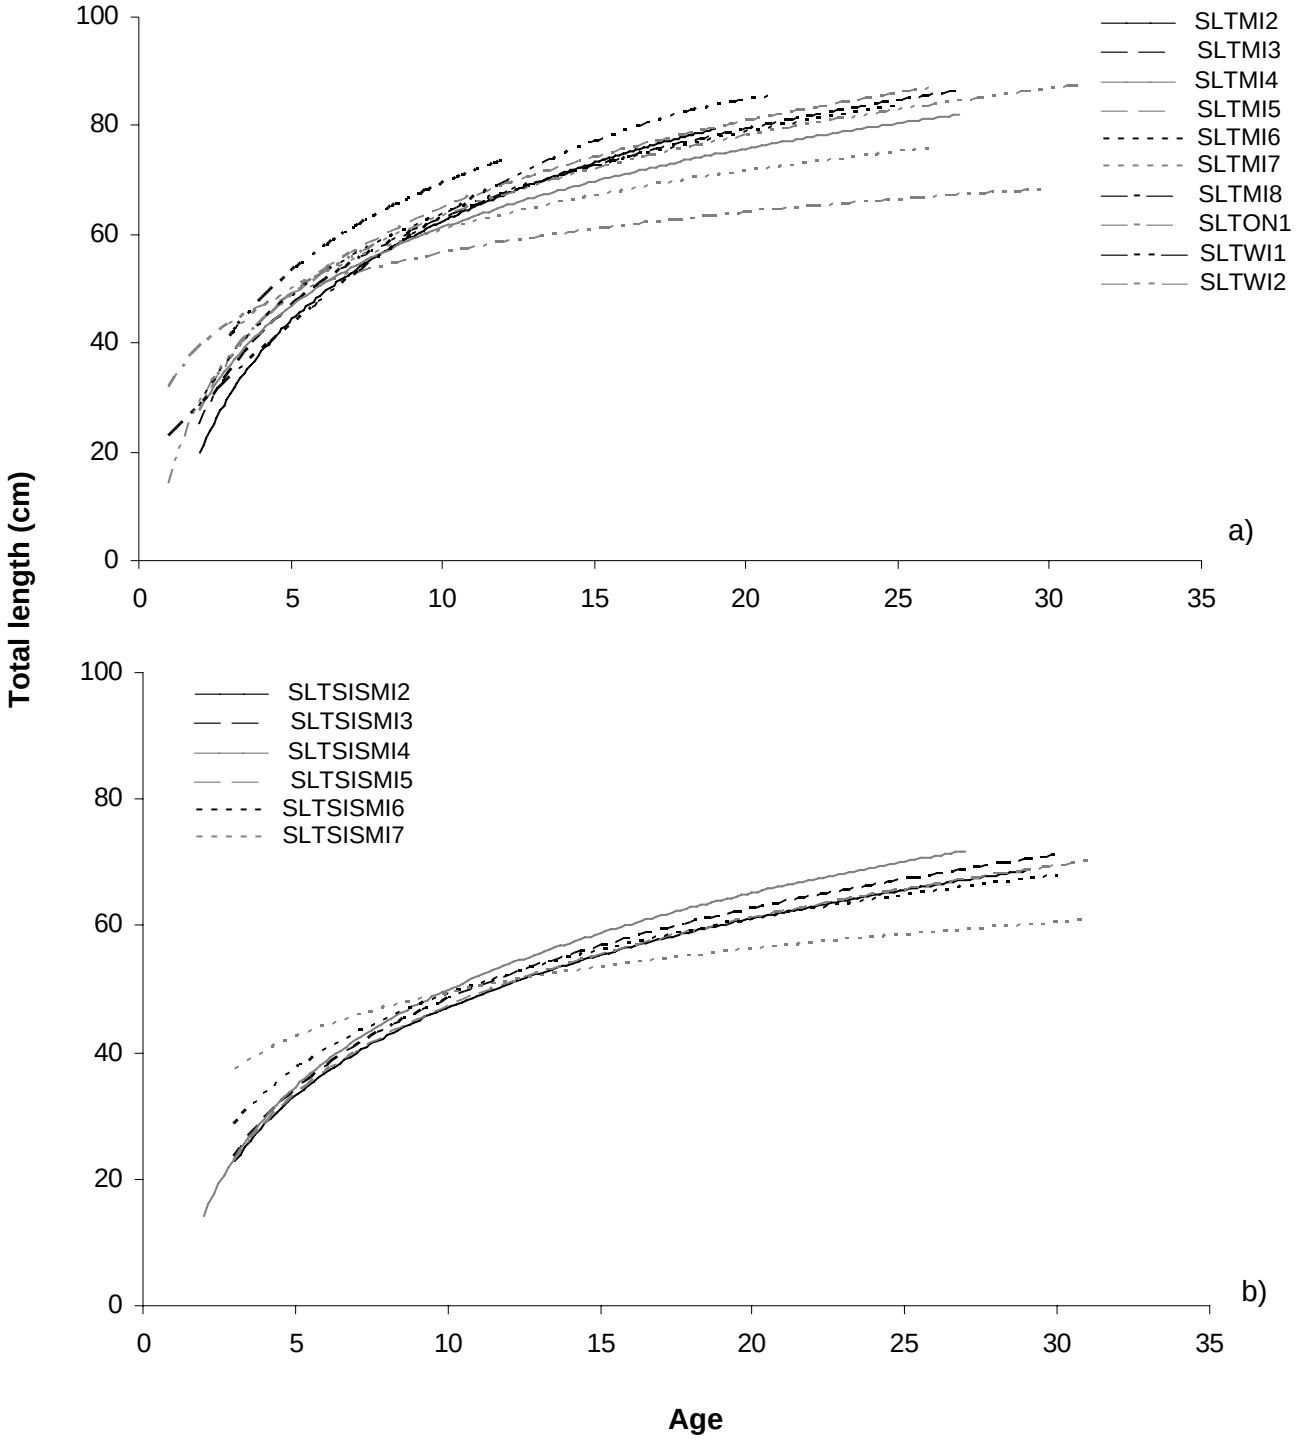

Figure 13. Growth curves for a) 10 lean lake trout and b) 6 siscowet lake trout populations in Lake Superior. Population codes correspond to Figures 1-3.

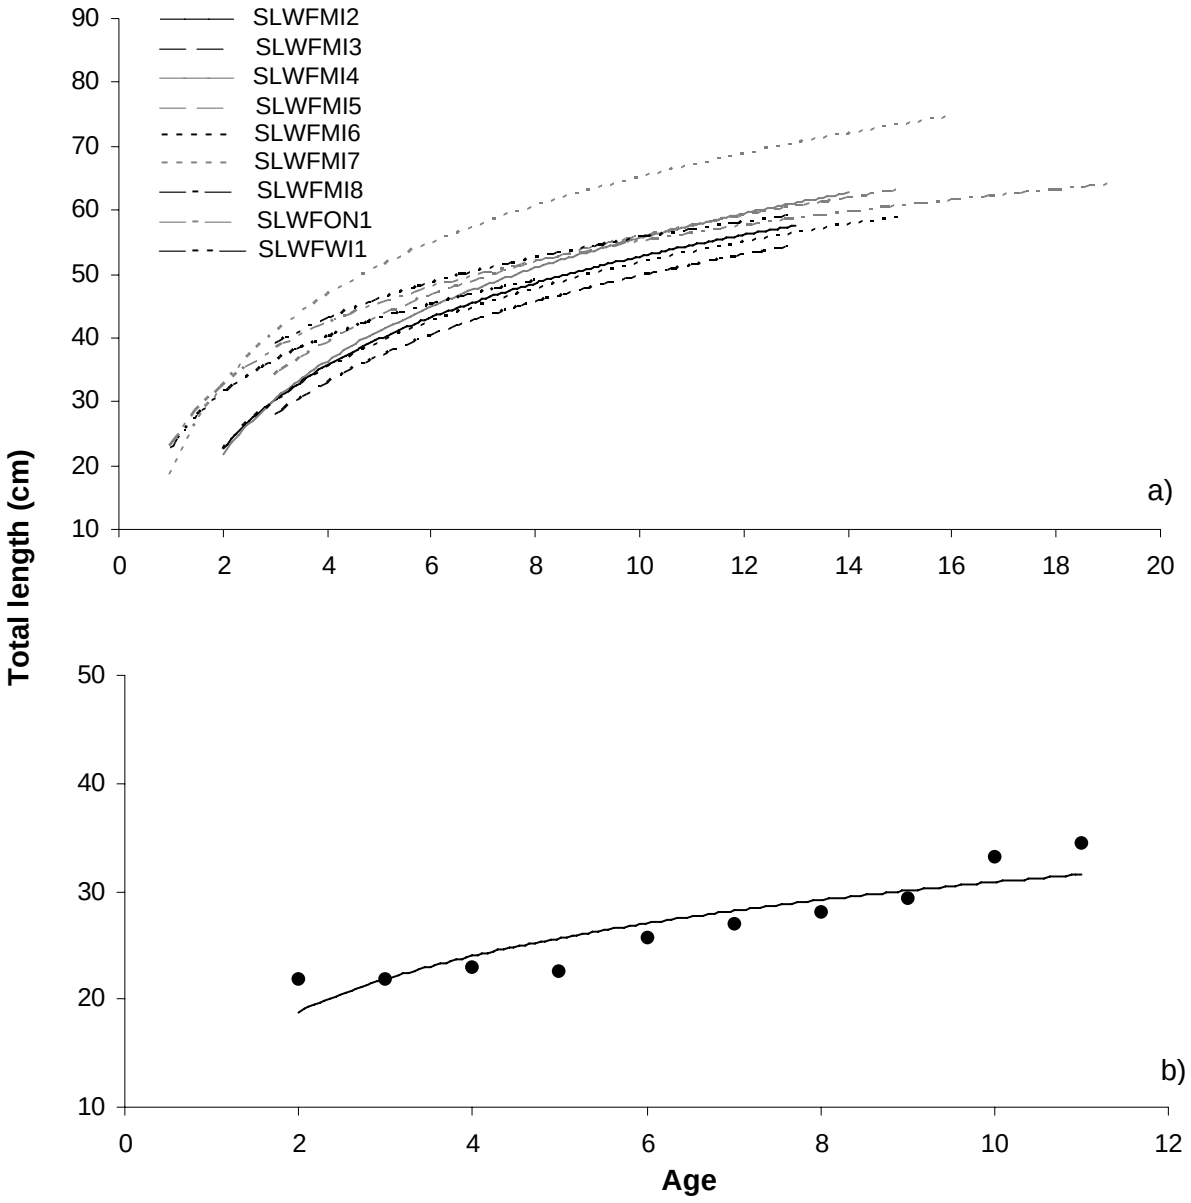

Figure 14. Growth curves for a) 9 lake whitefish population and b) 1 yellow perch population in Lake Superior. Population codes correspond to Figures 1-3.
