This is the 9th Technical Report from the Central and Arctic Region, Winnipeg

[^0]
## PREFACE

This report is presented in fulfillment of Department of Supply and Services Contract DSS 25 S.T.A. 7135-05-0003 let to the Keewatin Wildife Federation to conduct a wildiffe harvest study in the Keewatin Region = Phase III. The work was done on behalf of the Federal Government departments of Environment Canada (Canadian Wildlife Service), Fisheries and Oceans (Western Region), and Indian Affairs and Northern Development; the Government of the Northwest Territories Department of Renewable Resources; and the Keewatin Wildlife Federation.

The report is accepted upon recommendation by the steering committee for the study made up of representatives of the agencies noted above (Appendix 1) and chaired initially by Mr. F. McFarland and subsequently by Ms. D. Stewart of the Department of Indian Affairs and Northern Development. The harvest study material is published under the auspices of the DFO technical report series by agreement of the steering committee in order to ensure that the data achieve a wide circulation, be accessible to the interested public, and be published in a standardized format generally recognized as appropriate for the dissemination of such information.

A report of the study in Inuktitut will also be published as an insert to the periodical Caribou News (Contact Caribou News c/o Nortext Information Design Ltd., Suite 200, 16 Concourse Gate, Nepean, Ontario, K2E 7S8).

Gamble, R.L. 1987. Native harvest of wildlife in the Keewatin Region, Northwest Territories for the period October 1984 to September 1985. Can. Tech. Rep. Fish. Aquat. Sci. 1544: v + 59.

Harvest data were collected from Inuit hunters of the Keewatin Region for the period October, 1984 to September, 1985 as part of an ongoing collection of such information which began in September, 1981. The project has been run by an Inuit organization, the Keewatin Wildlife Federation, supported by funding provided through interested federal and territorial government departments. This report is an update and supplement to previous reports (No. 1282 - 1543) which cover the earlier years of the survey. Results were aggregated at a community level and fieldworkers continued to maintain a high level of performance as measured by participation of hunters in the study and a subjective judgement of the quality of data based on experience.

Key words: resource management; catch statistics; domestic harvest; monitoring; food resources; country foods; terrestrial mammals; marine mammals; birds; fish; computerized harvest study; Inuit organization.

## RÉSUMÉ

Gamble, R.L. 1987. Native harvest of wildlife in the Keewatin Region, Northwest Territories for the period October 1984 to September 1985. Can. Tech. Rep. Fish. Aquat. Sci. 1544: v + 59 p.

Des donnëes sur les prises/captures ont été recueillies auprès de chasseurs inuit de la région du Keewatin pour la période d'octobre 1984 à septembre 1985, dans le cadre d'un programme continu de collecte, entrepris en septembre 1981, dont un organisme inuit, la Keewatin Wildife Federation, assure l'application. Le financement pour le projet vient des ministères fédéral et territorial en cause. Le rapport constitue une mise à jour et un complément aux rapports précédents (no. 1282 et 1543), qui portent sur les annēes antérieures visēes par l'étude. Les résultats ont été groupés par collectivité. Le travail de collecte a étē fait de façon excellente, comme l'indiquent la participation des chasseurs à l'étude et l'évaluation subjective de la qualitē des données, fondée sur l'expérience.

Mots-clés: gestion des ressources; statistiques sur la prises; chasse/pêche de subsistance; contrôle; ressources alimentaires; ressources alimentaires indigènes; mammifères terrestres; mammifères marins; oiseaux; poisson; étude des prises/captures par ordinateur; organisation inuit.

## INTRODUCTION

The collection of harvest data for this study hegan in September, 1981. Previous results have been published for the period nctober 1981 to September 1983 (Gamble 1984), and for the period nctober 1983 to September 1984 (Gamble 1987). This report covers the period October 1984 to September 1985. Throughout this report hunter, harvester, trapper and fisherman are used as synonyms. Hunter is defined in the MATERIALS AND METHODS section below.

The main objectives of the study as specified in the contract covering the period of this report were to:

1) determine by survey techniques the hunter kill (i.e. harvest) hy Inuit living in District of Keewatin communities and outpost camps;
2) develop an approach for the collection of timely, statistically reliahle data on wildlife harvesting which could he undertaken by an agency such as the Keewatin Wildlife Federation (KWF) upon completion of the preliminary study;
3) determine the number of Inuit directly participating in subsistence harvesting in each community and to compare the proportion of harvest taken by hunters of different ages;
4) provide an estimate of the harvest sufficient to determine a measure of its value to each community as food or income, and
5) analyze and puhlish the data collected in a timely report and scientifically acceptable format.

The study area (Fig. 1) remained the same as reported in Gamble (1984; 1987) and includes the entire Keewatin district of the Northwest Territories (approximately $386,000 \mathrm{~km}^{2}$ ). This region contains seven permanent communities. Listed alphabetically (the convention followed throughout this report) they are Raker Lake, Chesterfield Inlet, Coral Harbour, Eskimo Point, Rankin Inlet, Repulse Ray and Whale Cove. Current information about these communities including population can be ohtained from the NWT Data Book (1984).

## MATERIALS AND METHODS

## general

For this survey period fieldworkers continued to try and include $100 \%$ of the region's hunters in their monthly data collection. The study design remained the same as originally described in Gamble (1984).

For the purpose of this study the term hunter includes all Inuit males and females over
the age of 16 who hunt (they may or may not have a NWT general hunting licence), Inuit youths under 16 who hunt regularly, and some long-term residents in the area of other ethnic origin who hunt. This latter group makes up less than $1 \%$ of the total hunters in the region and also accounts for less than $1 \%$ of the animals harvested.

Harvest data were aggregated at the community level. Separate coverage of outpost camps was not necessary hecause Inuit hunting from such locations visited their home communities frequently during the survey period and it was possible to include their harvest together with that of community based hunters on a consistent basis.

In accordance with contractual requirements, a steering committee (Appendix 1), as outlined in the preface, continued to provide guidance to the Harvest Study staff.

## HUMAN RESOURCES AND MATERIALS

Fieldworkers were hired in each of the seven communities to interview hunters and collect data. Duties included explaining the project to hunters; distributing the study materials (calendars and field notehooks) to hunters; keeping an up to date list of hunters; interviewing hunters beginning on the first day of each month to collect harvest statistics for the previous month and recording this information on the appropriate data sheets; making sure the data collected were as accurate as possihle; and promptly forwarding a monthly report following an interview period to the Project Riologist located at Rankin Inlet.

The Project Dffice organization remained the same as described by Gamble 1987 and no changes were made to the data sheets, calendars and field diaries distributed to fieldworkers and hunters.

## dATA COLLECTION AND ANALYSIS

The system used to analyze harvest data and to arrive at estimates of the total hunter kill by community required several steps and remained the same as developed during the 19811983 preliminary study (Gamble 1984).

Beginning on the first day of each month fieldworkers began interviews so that they could divide the hunter population for each community into the survey categories defined helow and list the number of animals killed per species for successful hunters who were interviewer. The monthly interval was defined as an interview period and covered the previous month of hunting. The fieldworker submitted this information to the Project Office where the data were summarized each month against a master list of hunters for individual communities and then entered into the computer. The numbers in some categories were subsequently adjusted the following month (i.e. the second month past the actual hunting episode) if acceptable reports
were submitted by fieldworkers on hunters who had been interviewed after a particular interview period had passed. Acceptable reports were determined through a subjective judgement by the Project Biologist based on his experience and a comparison of late reports with the reports submitted on time.

## Definition Category

1) The number of hunters who report $A$ taking a harvest during an interview period (i.e. successful).
2) The number of hunters who report B they were not successful in taking a harvest during an interview period (i.e. unsuccessful).
3) The number of hunters who report they did not hunt during an interview period (i.e. didn't hunt).
4) The number of hunters who were out D hunting during the interview period but who were not interviewed (i.e. hunted but not interviewed).
5) The number of hunters who were out $E$ of the area of the harvest survey during the interview period for any reason (i.e. out of hunt area).
6) The number of hunters within the harvest study area during the interview period whose activities were unknown (i.e. activities unknown).

It should be noted that the number of hunters in categories $D$ and $E$ for any month is usually known with a high degree of accuracy because of the small size of the communities involved and common local knowledge concerning the whereabouts of individuals, especially when it pertains to trips outside the local area.

Subsequently the summarized monthiy information contained in categories $A$ through $F$ was used to calculate ratios of participation and hunter success (Gamble 1987). Participation ratio refers to the percent of hunters in each community who were interviewed as part of the study in relation to the total number of hunters who could have hunted each month. The hunter success ratio was applied to hunters in categories $D$ and $F$ to obtain an estimate of probable hunter success within these groups. The results for all categories were summed to get an estimate of total hunter success and to calculate the theoretical kill factor. This is the value by which the reported kill per species is multiplied to arrive at the estimated harvest.

For the purpose of this analysis four main assumptions were made:

1) The involvement of hunters in the harvest is the same for those whose activities are unknown as for those that are known.
2) The success ratio is the same for hunters who hunted in the unknown categories as for the known categories.
3) The probability of a kill of any individual animal is the same for all species when calculating the estimated harvest.
4) Reported kills are accurate.

Topolniski and Thompson (1984) suggested changes in calculating the theoretical kili factor as given by Gamble (1984). Appendix 2 compares the two methods and Tahle ?2 gives the results for each month of the 1984-85 survey period for each community using both methods to calculate the monthly theoretical kill factors. As a consequence of this comparison the original formula given by Gamble (1984) was used to calculate estimated harvests for this report (see DATA PROCESSING and RESULTS below).

## DATA PROCESSING

The study continued to use the programs described by Gamble (1984; 1987). No additional programs were developed in the fourth year of the study due to financial constraints. For instance in the case of Fig. 2, 3 and 4 these are currently produced by hand from printouts of the kill by zonal grid. The capability to provide such information would be greatly enhancerd by the development of a graphics programme to automatically produce such figures from the data.

The participation file was modified to reflect the formula correction suggester by Topolniski and Thompson (1984) to retermine the theoretical kill factor such that either methor can be used to calculate this value. However no changes were made to the original methods of Gamble (1984) in order to maintain continuity and comparability of data between years. Variance between the calculated values in Table 22 using either method is small.

When referring to age the range of age classes are $0-15,16-30,31-45,46-60,61-75$ and 76-99. The age group $76-99$ was used as a category for hunters with unknown ages because only 8 hunters of known age fell within this group.

## RESULTS

Tables 1 through 21 summarize the results from analysis of the data collected between nctober 1984 and September 1985. Tahles 1 through 7 give the reported monthly harvest by species expressed as numbers of animals, and gives the percent of hunters reporting each month from the total number of known hunters in a given community (i.e. participation ratio). Tables $\&$ through 14 give the estimated monthly harvest by species expressed as numbers of animals, while Tables 15 through 21 give the annual reported and estimated harvests and also provide the mean monthly harvest per hunter together with the standard deviation about the mean.

Tables 1,8 and 15 give information for the community of Baker Lake for a 12 month period. In this area caribou from three different herds are harvested and this causes a problem in assigning kills to a particular herd. Hunters are sometimes not specific enough about location to allow a particular kill to be assigned to a herd nor is it always known which herd is in a specific area over a given time period. In such cases the kill is put in the category of unknown
herd. In some seasons this problem is exacerhated because caribou from the three herds intermingle. However for the 1984-85 survey period the herds remained geographically distinct from one another. An interesting observation is that calves and adult females from the Wager Ray herd were harvested northeast of Raker Lake in an area not previously known as a calving ground for any herd. The muskox harvest of 5 animals reported for Baker Lake for this survey is incorrect because it is known from Government of the Northwest Territories (GNWT) records that the full quota of 12 animals was taken.

Tables 2, 9 and 16 give harvest levels for the community of Chesterfield Inlet for a 12 month period. Though the percent of hunters reporting is high, the reported harvest is low. One would expect comparable sized communities such as Whale Cove and Chesterfield Inlet to exhibit similar harvest levels given equal access to game. Public consultation and contact with the community Hunters and Trappers Association suggests that hunters support the study but many expressed concern that they are not being contacted. This problem has been noted for previous survey periods (Gamble 1987) and project staff believe that at Chesterfield Inlet the harvest statistics are not being collected correctly. Changes in fieldworkers and the training provided to them has not provided any significant change in results. This is an ongoing problem toward which efforts must continually be directed. The division of caribou into herds by location was treated in the same fashion as the preliminary report (Gamble 1984).

Tahles 3 , 10 and 17 give harvest levels for the community of Coral Harbour for a 1 ? month period. Although data collection was consistent for the first time during the study, some improvements in participation are still necessary. Medical problems of the original fieldworker for this survey period may have contributed to the situation. Such personnel factors are an example of contributing influences which are beyond the control of a study such as this that can affect the results obtained.

Tables 4,11 and 18 give the harvest information for the community of Eskimo Point for a 12 month period. Over the course of the survey perior Eskimo Point had three fieldworkers. This may have had an effect on the collection of harvest data particularly in May and June. Information collected for these months was taken later than normal and hunter recall may decrease over time. If so, experience indicates that Inuit hunters are more likely to underestimate than overestimate a harvest after an extended period of time has elapsed.

Tables 5, 12 and 19 give the data collected for a 12 month perion at the community of Rankin Inlet. Collection effort was consistent and more than $80 \%$ of the hunters participated throughout the year unlike previous years (Gamble 1987). Commercial landings for Arctic charr were not reported with the domestic harvest for this survey period.

Tables 6, 13 and 20 give the data received from Repulse Ray for a 12 month period. At the
start of this survey period 84 hunters were identified from the community list as living in this community. This modified number was used to calculate theoretical kill factors (Table 22) rather than the figure of 90 hunters user for previous survey periods (Gamble 1984; 1987) because it is a more current estimate of the number of hunters residing in Repulse Ray. However emigration and to a lesser extent immigration of hunters continues to make it difficult to establish an accurate hunter list for this community. The participation ratio is still probably underestimated and the estimated harvest slightly overestimated because it appears there are slightly fewer hunters than the morified numbers used.

Tables 7, 14 and 21 show the harvest reported by the community of Whale Cove for a 1 ? month period. The participation ratio of hunters reporting was not available for October, 1984 hecause of the unannounced resignation of the community fieldworker which resulted in insufficient notice to insure continued collection of all data in October. Given these circumstances, the best estimate of that month's total community monthly harvest was taken to be the reported harvest following Gamble (1984).

Table 22 gives the monthly theoretical kill factors calculated following the procedure described in Appendix 2. Error is greatest for those values significantly larger than one as discussed by Gamble (1984). The values derived by using the original method described by Gamble (1984) were used to calculate estimated harvests rather than the modified method suggester by Topolniski and Thompson (1984) in Appendix 2. The original method was chosen for two reasons: 1) to facilitate comparison of the results between survey periods (i.e. Oct. 1981 to Sept. 1983 and Oct. 1983 to Sept. 1984), and 2) the observed error between the methods was very small.

Tables 23 through 29 give kill statistics for each species over the range of age groups for hunters for each community. The data on animals harvested by hunters of unknown ages were not included.

Table 30 gives the age distribution of hunters for the seven communities in the region for this survey period. Revisions to the hunter list used in previous survey periods have reduced the number of known hunters for each community when compared to Gamble (1984; Table 21) and Gamble (1987; Table 36).

Table 31 provides data on hunters who were successful in obtaining a harvest over the range of age of hunters. The distrithution of successful hunters is expressed as a percentage over the range of ages by month and harvest year for each community and as a regional total. In this table there were no hunters reporting in the age category 0 to 15 for the community of Chesterfield Inlet.

Table 32 gives the estimated individual species values for edible weight (kg) used to calculate the total edihle weights given in Tables 33 and 34. These individual values were
defined using the information ssurces noted in Gamble (1984, Table 16). The total reported edible weight values for the survey period are the sum of the annual species values. Therefore, totals from Table 33 and 34 differ slightly due to rounding off.

Table 35 provides a list of prices (circa January 1985) for country products sold at Frobisher Bay (new name Iqaluit) and meat and fish sold commercially in the Keewatin to assist. in determining the importance of the resource economy to Inuit in this region. The assumption is that all edible products are consumed.

Figures 2, 3 and 4 are zone maps showing the harvest by location for the survey period of ringed seal and eider for all communities, and caribou for Baker Lake. The harvest of ringed seal and eider are presented annually while the harvest of caribou is shown monthly.

Figures 5, 6 and 7 show graphically the relative frequency of caribou, ringed seal and snow geese harvested per hunt for the survey period. Data were not available or sample sizes were too small to provide a histogram for particular species in some communities.

## DISCUSSION AND CONCLIISIONS

Data collected during the September 1984 to October 1985 survey period were part of an ongoing collection of such information which began in September, 1981. Since the objectives of this study have not changed appreciably since the preliminary report (Gamhle 1984) this report is simply an update and supplement to existing information. During this survey period the reporting rates have levelled off to a near maximum. It is difficult to foresee any improvement to the study which would increase overall reporting rates. The errors still inherent in the current study are primarily the results of influences such as financial constraints which are beyond the control of the project and internal problems such as fieldworker turnovers which will always exist and must be constantly monitored. Over the longer term hunters may suffer reporting fatigue but at present this is not evident.

In conclusion, the Keewatin Wildife Federation Harvest Study has been successful in its attempt to elicit statistically valid harvest information from hunters using a survey technique cormon in a Euro-Canadian setting but intrinsically foreign to the Inuit. The preliminary work has laid the foundation for a process involving native people in the gathering of harvest statistics. This information will be important for jointly establishing with government management agencies a wildlife management rationale for the harvest of species which are of national interest and very particular cultural importance to Inuit. Continued cooperation amongst harvesters and wildiife managers will ensure the long term well being of wildife in this region.

The results obtained during this survey period continue to maintain the high level of performance reported in previous survey periods (Gamble 1984, 1987).

## ACKNOWLEDGMENTS

I thank the Keewatin Wildlife Federation, which was supportive of this study and provider valuable assistance at a regional and community level.

Thanks are also due to members of the steering committee who provided valuable criticism of my manuscript, in particular R. Peet (DFO) and his staff who assisted in the preparation of the final draft. I particularly thank the staff of the Keewatin Wildifife Federation "Harvest Riology Study": Veronica Curley, Oscar Jajalla, Jean Kusugak, and Karen Sataena. Their continued efforts in conjunction with the various community fieldworkers made this report possible.

I also thank all the hunters who provided data on their harvests and especially thank them for their cooperation and understanding in the face of repeated questions.

Finally I acknowledge the logistic support given to the study by the Regional Government of the Northwest Territories.

${ }^{1}$ In this table there are two situations where reported and estimated values are equal:
a) The theoretical kill factor (Table 22) is the value hy which the reported kill per species is multiplied to arrive at the estimated harvest. In cases where this value is one then $100 \%$ of the hunters have heen interviewer and the reported and pstimated harvests are equal.
b) For the community of whale Cove for the month of nctoher 1984 no data was collected on hunter participation. Consequently no meaningful theoretical kill factor could he calculater. In this case the hest estimate of harvest was taken to he the reporter harvest.

THE NUMBER OF CARIBOU HARVESTED PER HUNTER PER TRIP

Fig. 5. Histogram showing the percent relative frequency of caribou harvested per hunt by hunters fron the seven Keewatin communitier: for the period October 1984 to September 1935.

Fig. 6. Histogram showing the percent relative frequency of ringed seal harvested per hunt by hunters for the period October 1984 to September 1985.

Fig. 7. Histogram showing the percent relative frequency of snow geese harvested per hunt by hunters for the period October 1984 to September 1985.

Appendix 1. Members of the Steering Committee for the Keewatin Wildlife Federation Harvest Study.

Chairpersons

Mr. F. McFarland
and
Ms. D. Stewart
Members

Northern Affairs Program, Department of Indian Affairs and Northern Development.

| Mr. R. Cole | Canadian Wildlife Service, Department of the <br> Environment. |
| :--- | :--- |
| Mr. R. Graf | Department of Renewable Resources, Government of the <br> Northwest Territories. |
| Mr. R. Peet | Department of Fisheries and Oceans. |
| Mr. A. Angootealuk President, Keewatin Wildlife Federation. |  |
| Mr. L. Gamble | Regional Resource Manager, Keewatin Harvest Study. |
| Ms. V. Curley | Assistant Regional Resource Manager, Keewatin Harvest <br> Study. |

Appendix 2. Calculation of Estimated Harvest.
This appendix lists the steps used to arrive at an estimate of total monthly hunter kill using the interview data from Eskimo Point, September, 1982 and shows an alternative method of calculating the theoretical kill factor as suggested by Topolniski and Thompson ( D . Topolniski and P . Thompson 1984).

The letter designations for each category are defined in the text under the section on data analysis. The bracketed statement is a shortened designation for these definitions for the purposes of this appendix.
I. Interview Data, Eskimo Point, September, 1982.

| Category | Number of hunters |  |
| :---: | :--- | :---: |
| A | (successful) | 102 |
| B | (unsuccessful) | 23 |
| C | (didn't hunt) | 85 |
| D | (hunted but not interviewed) | 14 |
| E | (out of hunt area) | 6 |
| F | (activities not known) | 8 |

II. Calculations common to both methods

1. the known number of hunters who hunted $=A+B=102+23=125$.
2. the success ratio of the hunters that hunted and were interviewed $=$

$$
\frac{A}{A+B}=\frac{102}{102+23}=0.816=G
$$

3. the estimated success of those out hunting but not interviewed $=$ $G \times D=0.816 \times 14=11.4=H$
4. the total number of hunters whose activities are accounted for $=$ $A+B+C+D+E=102+23+85+14+6=230=1$
5. the total number of hunters that could have hunted $=$ $I+F=230+8=238=J$
6. the participation ratio $=\frac{A+B+C}{J} \times 100=\frac{102+23+85}{238} \times 100=$ 88.2\%
7. the estimation of mean monthly kill by species $=N \times$ number harvested for each species from the fieldworker's reports for each hunter in Category A.
III. Calculations for the actual kill factor following Gamble (1984)
8. the estimated success ratio of successful hunters interviewed in relation to the total hunters whose activities are accounted for $=$ $\frac{A}{I}=\frac{102}{230}=0.444=K$
9. the estimated success of hunters whose activities are unknown $=$ $\mathrm{K} \times \mathrm{F}=0.444 \times 8=3.6=\mathrm{L}$
10. the estimated total success $=A+H+L=102+11.4+3.6=117=M$
11. the theoretical kill factor $=\frac{M}{A}=\frac{117}{102}=1.14=N$
IV. Calculation for theoretical kill factor following Topolniski and Thompson (1984)
12. the rate at which all hunters actually hunted $=$ $\frac{A+B+D}{I}=\frac{102+23+14}{230}=\frac{139}{230}=0.6043=K$.
13. the estimated success of hunters whose activities are unknown $=$ $F \times G X K=8 \times 0.816 \times 0.6043=3.94=L$.
14. the estimated total success $=A+H+L=102+11.4+3.9=117.3=$ M.
15. the theoretical kill factor $=\frac{M}{A}=\frac{117.3}{102}=1.15=\mathrm{N}$.

Table 22 compares the theoretical kill factors derived from both methods that were calculated for each month of the 1984-85 survey period for each community.

[^0]:    ${ }^{1}$ Present address 20 Amundsen Bay, Winnipeg, MB R3K 0V2. Former address Keewatin Wildlife Federation, Rankin Inlet, NT XOC nGO
