Canadian Technical Report of Fisheries and Aquatic Sciences

Technical reports contain scientific and technical information that contributes to existing knowledge but which is not normally appropriate for primary literature. Technical reports are directed primarily toward a worldwide audience and have an international distribution. No restriction is placed on subject matter and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Technical reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in *Aquatic Sciences and Fisheries Abstracts* and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-456 in this series were issued as Technical Reports of the Fisheries Research Board of Canada. Numbers 457-714 were issued as Department of the Environment, Fisheries and Marine Service, Research and Development Directorate Technical Reports. Numbers 715-924 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Technical Reports. The current series name was changed with report number 925.

Technical reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

Rapport technique canadien des sciences halieutiques et aquatiques

Les rapports techniques contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui ne sont pas normalement appropriés pour la publication dans un journal scientifique. Les rapports techniques sont destinés essentiellement à un public international et ils sont distribués à cet échelon. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports techniques peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports techniques sont résumés dans la revue *Résumés des sciences aquatiques et halieutiques*, et ils sont classés dans l'index annuel des publication scientifiques et techniques du Ministère.

Les numéros 1à 456 de cette série ont été publiés à titre de rapports techniques de l'Office des recherches sur les pêcheries du Canada. Les numéros 457 à 714 sont parus à titre de rapports techniques de la Direction générale de la recherche et du développement, Service des pêches et de la mer, ministère de l'Environnement. Les numéros 715 à 924 ont été publiés à titre de rapports techniques du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 925.

Les rapports techniques sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

ABSTRACT

King, J.R., McPhie, R.P., and Morrison, P.R. 2012. Biological results of the Strait of Georgia spiny dogfish (*Squalus suckleyi*) longline survey October 7-15, 2011. Can. Tech. Rep. Fish. Aquat. Sci. 2975: iii + 24 p.

From October 7 to 15, 2011, a spiny dogfish (*Squalus suckleyi*) longline survey was conducted in the Strait of Georgia aboard the *CCGS Neocaligus*. Fishing occurred at nine sites selected in previous surveys to be representative of commercial fishing areas: Active Pass, Porlier Pass, Sturgeon Bank, French Creek, Cape Lazo, Cape Mudge, Grants Reef, Sinclair Bank and Epson Point. Four depth strata were fished during this survey: 56 to 110m, 111 to 165m, 166 to 220m and deeper than 220m. All captured spiny dogfish were measured for length, weight and sex. Other encountered species were enumerated.

RESUMÉ

King, J.R., McPhie, R.P., and Morrison, P.R. 2012. Biological results of the Strait of Georgia spiny dogfish (*Squalus suckleyi*) longline survey October 7-15, 2011. Can. Tech. Rep. Fish. Aquat. Sci. 2975: iii + 24 p.

Nous avons effectué un relevé de l'aiguillat commun (*Squalus suckleyi*) à la palangre du 7 au 15 octobre 2011 dans le détroit de Georgia à partir du NGCC *Neocaligus*. La pêche a été pratiquée à 10 sites choisis lors de relevés précédents comme représentatifs de zones de pêche commerciale : la passe Active, la passe Porlier, le banc Sturgeon, le ruisseau French, le cap Lazo, le cap Mudge, le récif Grants, le banc Sinclair et la pointe Epson. Quatre strates de profondeur ont été échantillonnées : 56 à 110 m, 111 à 165 m, 166 à 220 m et les profondeurs de plus de 220 m. Nous avons établi la longueur, le poids et le sexe de tous les aiguillats capturés; et dénombré les autres espèces capturées.

INTRODUCTION

Spiny dogfish in the north Pacific were identified as a separate species from Atlantic spiny dogfish (Ebert et al., 2010), and their name was officially changed from *Squalus acanthias* to *Squalus suckleyi* in 2011. Spiny dogfish were an important component of Canada's Pacific fishery from the late 1800s to the mid 1950s (Ketchen 1986). A resurgence in interest in the fishery led to an increase in catches in the late 1970s, particularly in the Strait of Georgia. Based on tagging studies (McFarlane and King 2002), the Strait of Georgia stock is considered to be discreet. The increase in fishing catches in the late 1970s prompted the initiation of an assessment program. As part of this study, longline surveys were conducted in the Strait of Georgia in 1986 and 1989 (McFarlane et al 2005a), 2005 (McFarlane et al. 2006) and 2008 (King and McFarlane 2009) to provide biological, catch and effort data for selected sites. A longline calibration survey was conducted in 2004 to account for catch rate changes that might have occurred in the commercial fishery due to a change from using J-hooks to using circle hooks (McFarlane et al. 2005b). This report provides catch and biological summary data for a fifth survey conducted in the Strait of Georgia from October 7-15, 2011. It is our intention to continue these surveys on a tri-annual basis in order to monitor the status of spiny dogfish in the Strait of Georgia.

METHODS

From October 7 to 15, 2011 the spiny dogfish longline survey was conducted onboard the *CCGS Neocaligus*.

In the previous four surveys, longline fishing occurred at ten sites throughout the Strait of Georgia that were selected to be representative of commercial fishing areas. Logistical constraints (i.e., reduced ship days) meant that only nine sites could be surveyed in 2011 (Figure 1). The nine sites were surveyed in all previous years, and were selected to provide even geographic coverage of the Strait of Georgia that remained consistent with the previous five surveys. The sites were located near Active Pass, Cape Lazo, Cape Mudge, Epson Point, French Creek, Grant Reef, Porlier Pass, Sinclair Bank and Sturgeon Bank (see Appendix 1 for positional data). The Hornby Island site, which was included in the previous four surveys, was omitted from this survey. In previous surveys, fishing gear was deployed at each site in five depth strata:

1. less than 56 m
2. 56 to 110m
3. 111 to 165m
4. 166 to 220m
5. greater than 220 m

Due to time constraints, this survey fished strata 2-4 only. Stratum 1 was omitted since it previously had the highest rockfish bycatch, and it was previously omitted at sites when bad weather curtailed fishing time. At each site the four depth strata were fished in random order. Once the vessel arrived at the pre-selected site the appropriate depth range was located and fishing proceeded along the depth contour.

Each longline set consisted of 2 groundlines (5/16 inch leaded copolym) with an anchored buoyline (3/8 inch polysteel) hooked on at each end. Model 72 snaps (3 cm in width; 13 cm in length), made from 3.2 mm stainless steel wire, were snapped onto the groundline about every 2 meters as the gear was set. Attached to the snap, crimped Perlon snap gangions 30 cm long were fitted with circle hooks. Size #14/0 Mustad circle hooks were used. Each hook was baited with a third of a 6 inch herring.

At each location the groundline was deployed with 300 baited hooks per set. This number of baited hooks is consistent with the 2008 survey, but is lower than the three surveys preceding 2008, which used 500 baited hooks per set (1986 and 1989) or 400 baited hooks per set (2005). Hook number in the 2008 and 2011 surveys was reduced due to high catch rates in the initial three surveys, and to reduce the number of hours required to sample the catch. Differences in catch rates were assessed in 2008 when four extra sets were conducted at French Creek with 400 baited hooks per set (King and McFarlane 2009).

The effective fishing time for each set was recorded as the time from when the first hook was deployed until the last main groundline anchor was onboard. In order to minimize bias in catch rates due to differences in effective fishing time, all longline sets were fished for approximately 2 hours. The target 2 hour fishing time was recorded as the time from when the last hook was deployed, until the first main groundline anchor was onboard. Catch per unit effort (CPUE) for a longline set was calculated as the total number of spiny dogfish caught per thousand hooks.

All fish, other than those lost at the surface, were removed from the hooks, identified to species and counted. All spiny dogfish lost at the surface were noted and included in the total catch numbers. All spiny dogfish and the two bluntnose sixgill sharks (*Hexanchus griseus*) that were brought on board were sampled and released; other species were identified and immediately released.

Length, weight and sex were recorded from all captured whole spiny dogfish. Length was measured (mm) as the total length of the fish; from the tip of the snout to the tip of the upper lobe of the caudal fin when it was directed downward in a straight line with the body. Weight was determined to the nearest 0.01 kg and sex was determined externally. Non-linear regression was used to estimate the weight-length relationship:
$W = aTL^b$,
where W = weight (g), TL = total length (mm), and *a* and *b* are estimated parameters. Differences between male and female weight-length relationships were tested with ANCOVA based on natural logarithmic linear regression models.

RESULTS

From October 7-15, 2011, 10,500 hooks were set over 35 sets at 9 sites (Table 1). At each site, 4 depth strata were fished, except for Sinclair Bank where only 3 strata were fished due to gale force winds that caused the last set (stratum 3) to not be deployed. The

mean effective fishing time was 167 minutes, and the mean fishing time was 120 minutes (Table 1). A total of 6,706 spiny dogfish were captured, including those lost at the surface (n=54) or those hooked but predated (Table 2). Fifty-eight of the captured dogfish were predated, which has not been recorded to have occurred on the previous surveys. The predated spiny dogfish had tooth marks on them, and two bluntnose sixgill sharks were captured on this survey both of which were predating spiny dogfish captured on the fishing gear. Longnose skate (*Raja rhina*), quillback rockfish (*Sebastes maliger*), yelloweye rockfish (*S. ruberrimus*) and Pacific cod (*Gadus macrocephelus*) were the most frequent bycatch encountered (Table 2).

CATCH PER UNIT EFFORT

CPUE comparison by depth strata

For males, the CPUE was highest in stratum 3 but variable among depths; for females, the CPUE increased by depth (Table 3). The CPUE for all spiny dogfish increased with increased depth (Table 3). Depth stratum 3 was not fished at Sinclair Bank due to inclement weather, so comparison of CPUE by location will be compromised given the differences in CPUE by depth.

CPUE comparison by site

Sinclair Bank Excluded – When Sinclair Bank is excluded from comparison and all four depth strata are used to calculate CPUE by locations, the mean CPUE for all spiny dogfish was 640 fish/1000 hooks (Table 1). The CPUE for male spiny dogfish was typically higher than for female spiny dogfish, and the mean CPUE by site for male and female spiny dogfish were 468 fish/1000 hooks and 160fish/1000 hooks respectively (Table 1). Total CPUE by site ranged from 575 (French Creek) to 773 (Cape Lazo) fish/1000 hooks. Sites with the highest dogfish CPUE were Cape Lazo, Active Pass and Epson Point. French Creek, Grants Reef, and Porlier Pass had the lowest CPUE. Male spiny dogfish CPUE was highest at Active Pass and Cape Lazo; female spiny dogfish CPUE was highest at Sinclair Bank and Grants Reef (Table 1).

Sinclair Bank Included -For the three depth strata common to all locations (strata 2, 4 and 5) the mean CPUE for all spiny dogfish was 630 fish/1000 hooks (Table 1). The CPUE for male spiny dogfish was typically higher than for female spiny dogfish, and the mean CPUE by site for male and female spiny dogfish were 322 fish/1000 hooks and 158 fish/1000 hooks respectively (Table 1). Total CPUE by site ranged from 552 (Grants Reef) to 783 (Cape Lazo) fish/1000 hooks. Sites with the highest dogfish CPUE were Cape Lazo, Active Pass and Epson Point. Grants Reef, Cape Mudge and Porlier Pass had the lowest CPUE. Male spiny dogfish CPUE was highest at Active Pass and Cape Lazo; female spiny dogfish CPUE was highest at Sinclair Bank and Epson Point (Table 1).

LENGTH AND WEIGHT FREQUENCY

Length and sex were recorded for 6,586 dogfish, of these 6,582 had recorded weights. Of the 58 predated dogfish, 10 dogfish were sampled for sex of which 2 could also be sampled for total length. Detailed spiny dogfish length frequency catch data for sex by fishing site and sex by depth strata is presented in Tables 4 and 5 and Figures 2 and 3.

A total of 1925 female and 4653 male spiny dogfish were measured for total length (Table 4). Male spiny dogfish ranged in size from 298-986 mm with a mean length of 739 mm (Table 5). Female spiny dogfish ranged in size from 490-1156 mm with a mean length of 713 mm (Table 5). Both female and male dogfish mean total length decreased with increased depth (Table 5). The mean total length for male dogfish was greater than that of female dogfish in all except the shallowest stratum (t-test: $t_{0.05,6569}=10.45$, $p<0.01$; Table 5). The smallest spiny dogfish was a male (298 mm) caught in depth stratum 3 at Active Pass; the largest was a female (1156 mm) caught in depth stratum 2, also at Active Pass (Table 5).

By depth and location, the distribution of total length for male spiny dogfish was more uniform across the size range than that of female spiny dogfish, which often had a skewed or bimodal distribution (Figures 2 and 3).

A total of 1924 female and 4658 male spiny dogfish were measured for weight. Male spiny dogfish ranged in size from 170-3310 g with a mean weight of 1507 g (Table 6). Female spiny dogfish ranged in size from 380-5770 g with a mean weight of 1567 g (Table 6). There was a significant difference in the weight-length relationship (Figure 4, Table 7) between male and female spiny dogfish (ANCOVA: F=452.04, d.f. = 2, $P <$ 0.0001).

SEX DISTRIBUTION BY DEPTH STRATA AND SITE

Depth strata

For all of the nine sites combined in the Strait of Georgia, there was a larger proportion of male spiny dogfish caught in each depth strata (Figure 5). Female dogfish decreased in proportion from stratum 2 to stratum 3, after which, they were present in increasing proportion by depth (Figure 5).

Site

Seven of the nine sites had a larger proportion of male spiny dogfish ranging from 60% to 94% of the catch. At the remaining two sites, Epson Point and Sinclair Bank, female spiny dogfish proportions were 65% and 70% of the catch respectively (Figure 6).

ACKNOWLEDGMENTS

Thank you to the captain and crew of the *CCGS Neocaligus*. The survey was conducted by S. Garcia, R. McPhie and P. Morrison.

Table 4. Spiny dogfish total length frequency data, by 50 mm length intervals, from the spiny dogfish longline survey conducted in the Strait of Georgia onboard the *CCGS Neocaligus*, October 7-15, 2011.

Length interval	Number of males	Number of females
250-299	1	0
300-349	0	0
350-399	1	0
400-449	1	0
450-499	3	3
500-549	62	89
550-599	185	241
600-649	367	389
650-699	580	341
700-749	1133	248
750-799	1383	163
800-849	740	128
850-899	174	113
900-949	28	110
950-999	2	52
1000-1049	0	35
1050-1099	0	10
1100-1149	0	2
1150-1199	0	1
Total	4660	1925

Table 5. Summary of minimum, maximum and mean total length (mm) data for spiny dogfish captured by depth stratum (See Figure 2 for sample sizes) from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey.

	Male spiny dogfish				Female spiny dogfish			
Depth Stratum	n	Minimum	Maximum	Mean	n	Minimum	Maximum	Mean
2	840	510	949	767	334	507	1156	847
3	1240	298	986	745	353	505	1100	736
4	1344	440	944	728	561	491	1105	669
5	1236	440	965	725	677	490	995	670

Table 6. Summary of minimum, maximum and mean total weight (g) data for spiny dogfish captured by depth stratum from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey.

	Male spiny dogfish				Female spiny dogfish			
Depth Stratum	n	Minimum	Maximum	Mean	n	Minimum	Maximum	Mean
2	840	420	2860	1643	334	430	5770	2680
3	1239	170	3000	1547	352	380	5510	1800
4	1344	380	3140	1452	561	390	5580	1206
5	1235	320	3310	1430	677	380	4270	1196

Table 7. Weight-length parameters estimates derived from the eqaution $W = aTL^b$ for male and female spiny dogfish caught in the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey. R^2 is the square of correlation coefficient.

Sex	n	*a*	*b*	R^2
Male	4660	3.0×10^{-6}	3.021	0.93
Female	1925	5.0×10^{-7}	3.309	0.98

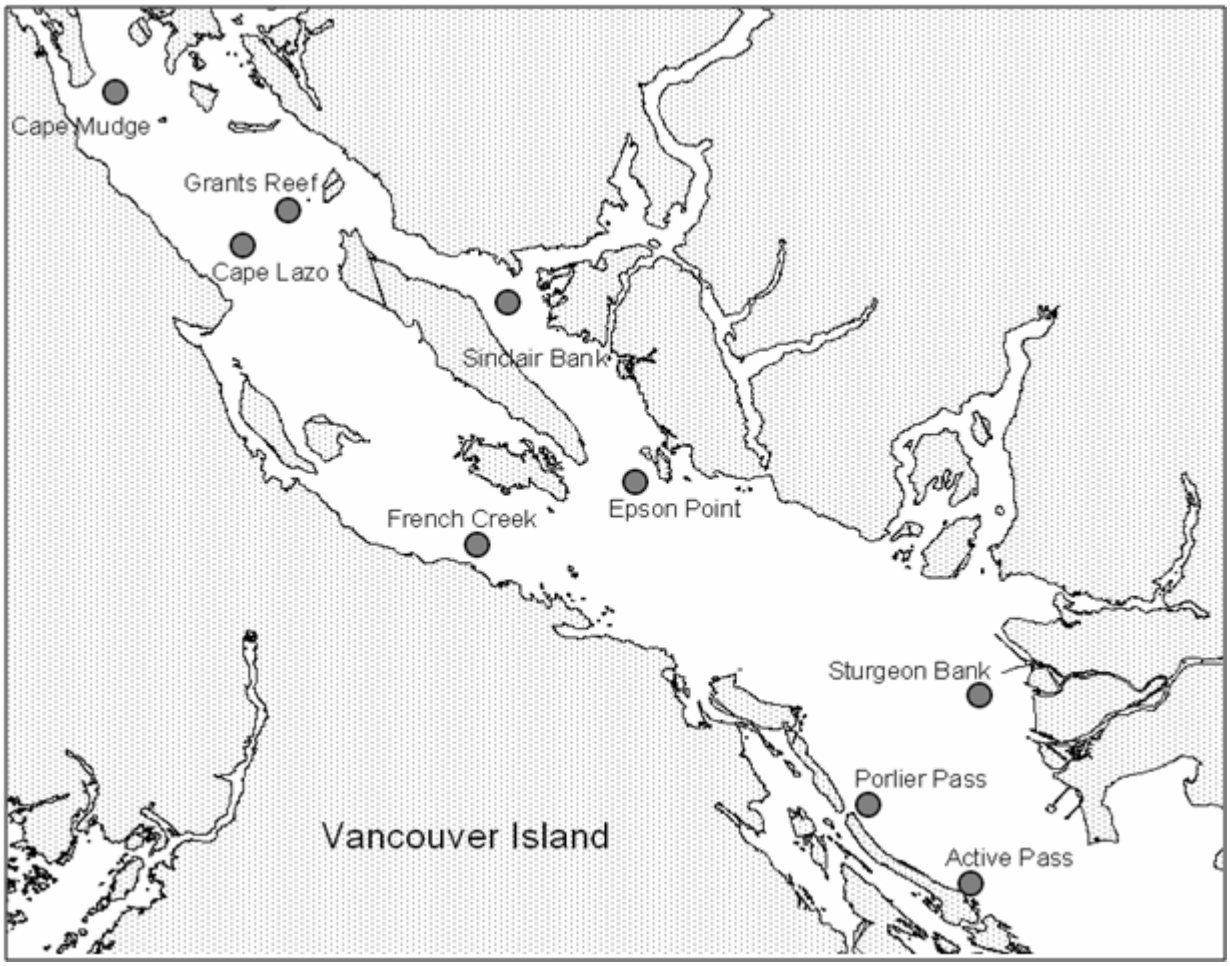

Figure 1. Set locations from the Strait of Georgia spiny dogfish longline survey conducted October 7-15, 2011. For detailed positional information see Appendix 1.

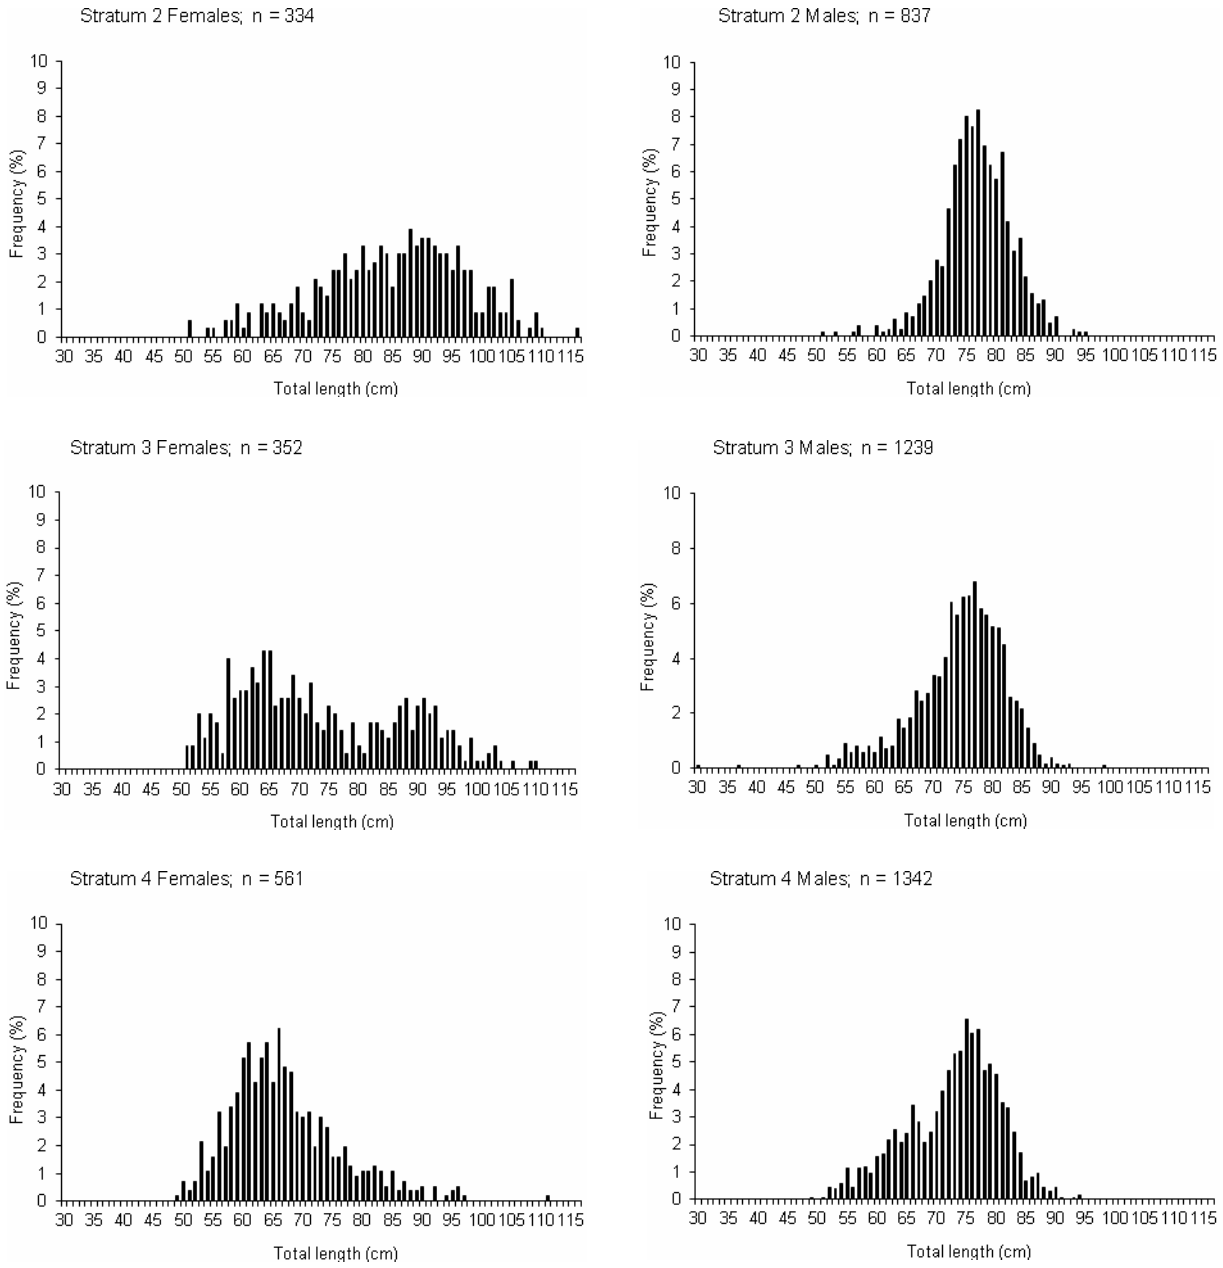

Figure 2. Spiny dogfish length frequency by sex and depth stratum (2: 56 to 110m, 3: 111 to 165m, 4: 166 to 220m and 5: deeper than 220m) from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey.

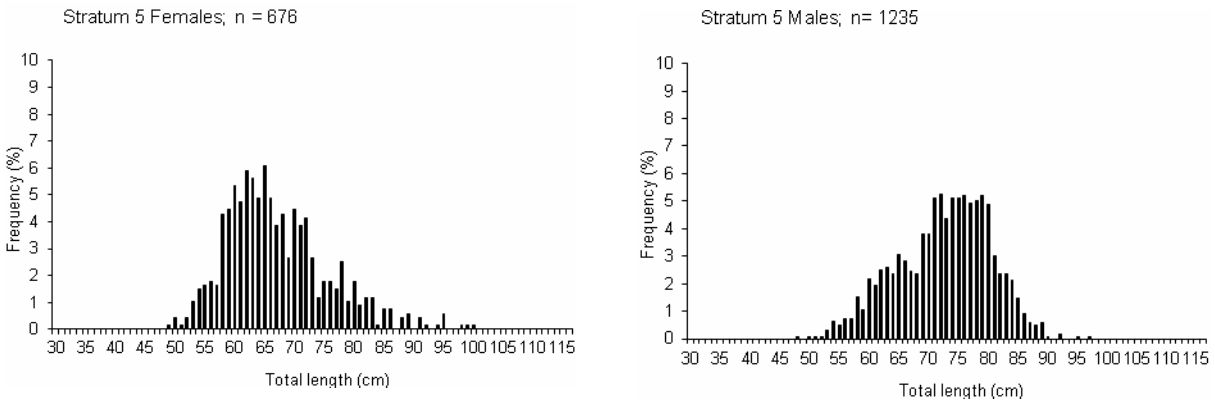

Figure 2 continued. Spiny dogfish length frequency by sex and depth stratum (2: 56 to 110m, 3: 111 to 165m, 4: 166 to 220m and 5: deeper than 220m) from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey.

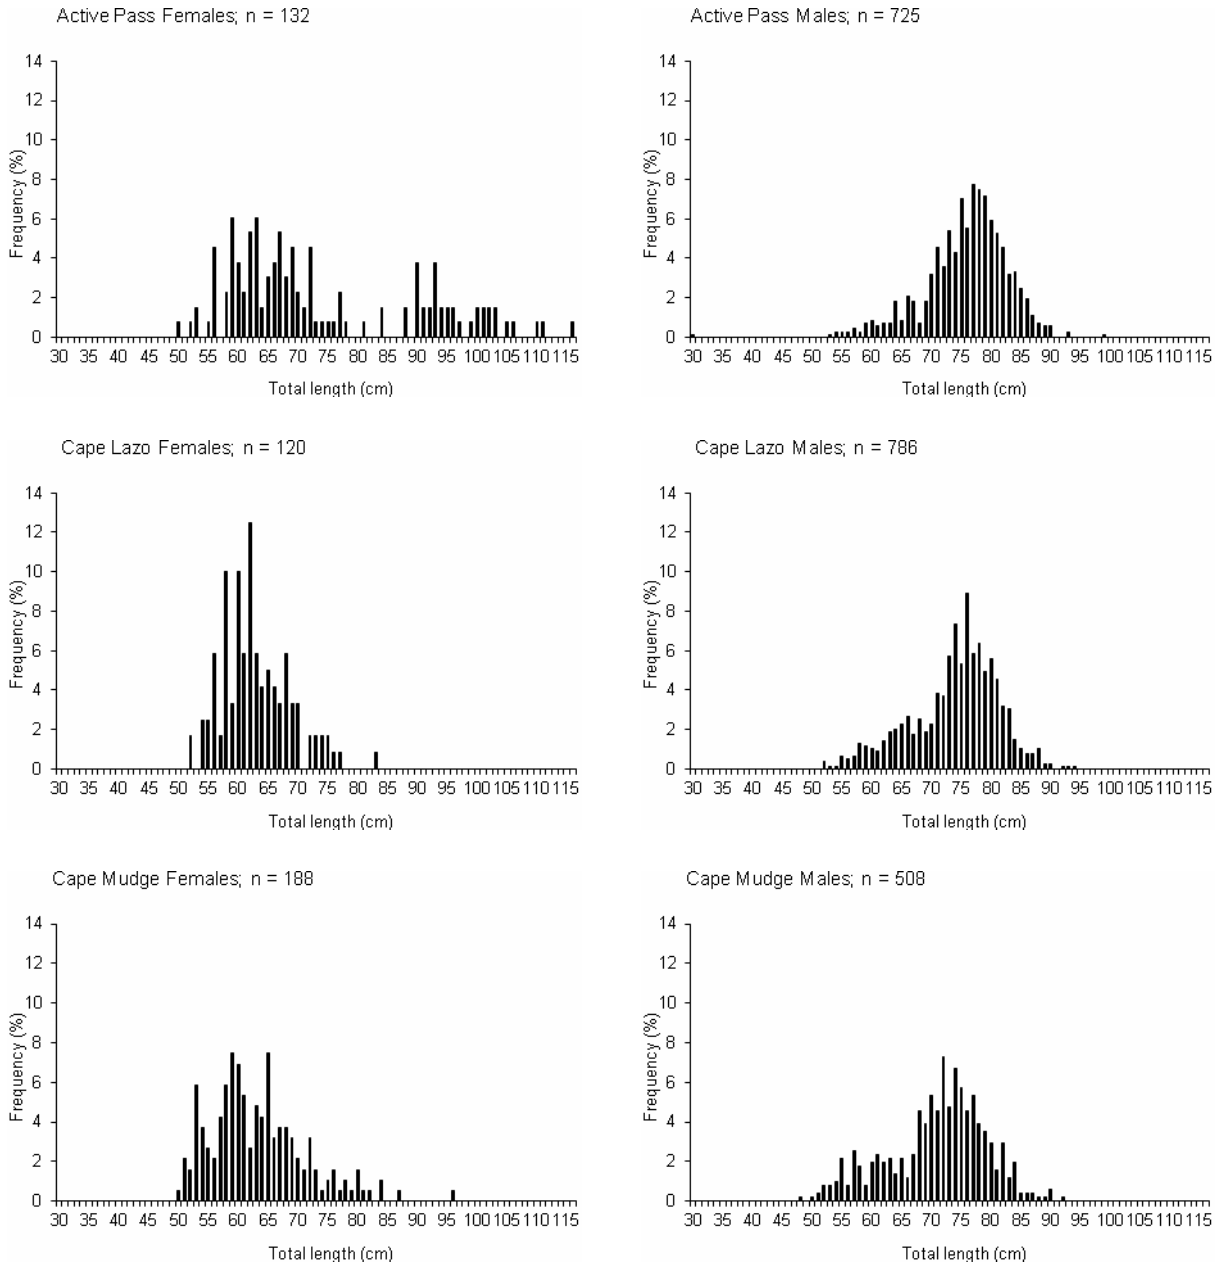

Figure 3. Spiny dogfish length frequency by sex and location from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey.

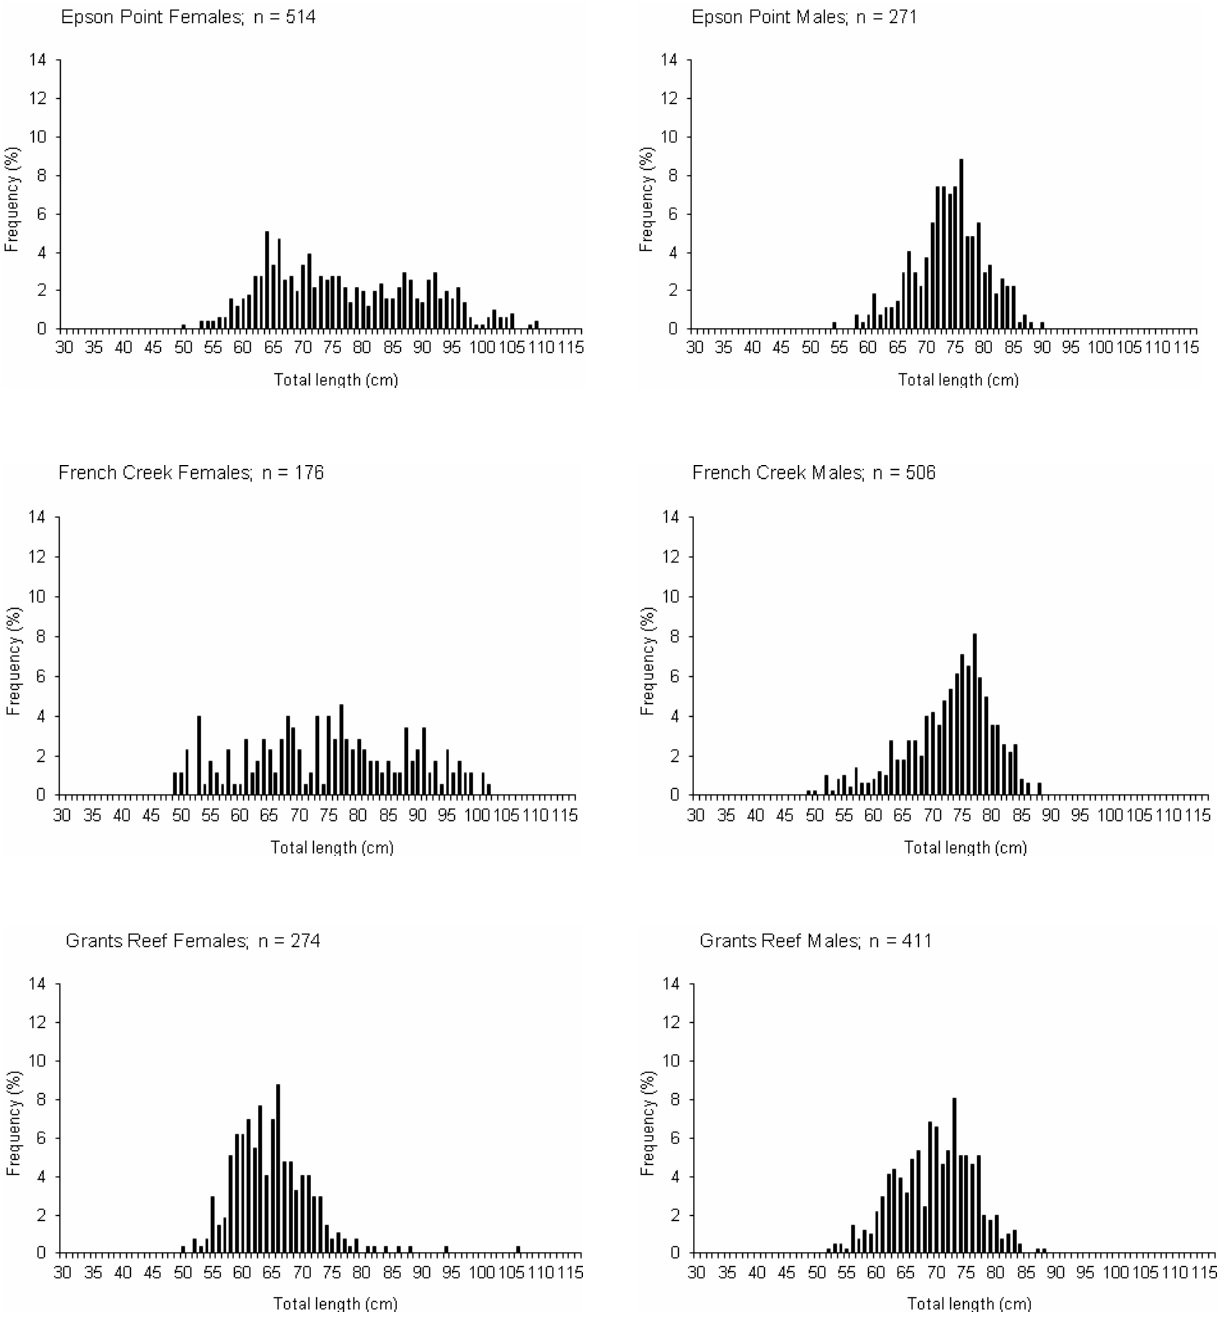

Figure 3 continued. Spiny dogfish length frequency by sex and location from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey.

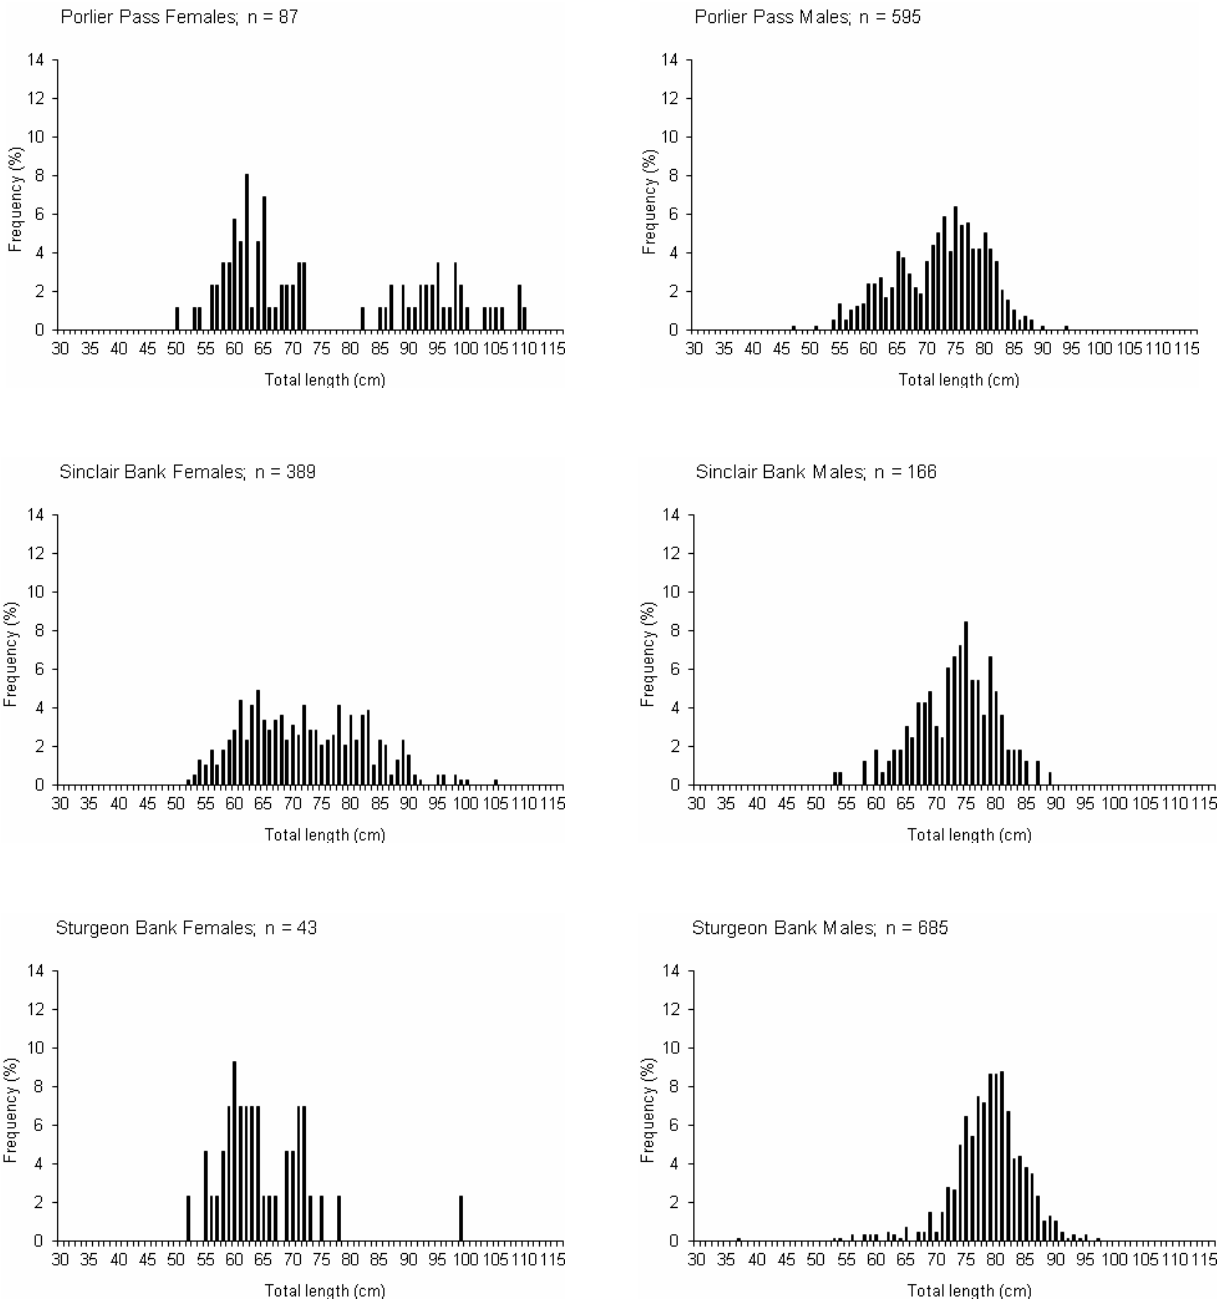

Figure 3 continued. Spiny dogfish length frequency by sex and location from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey.

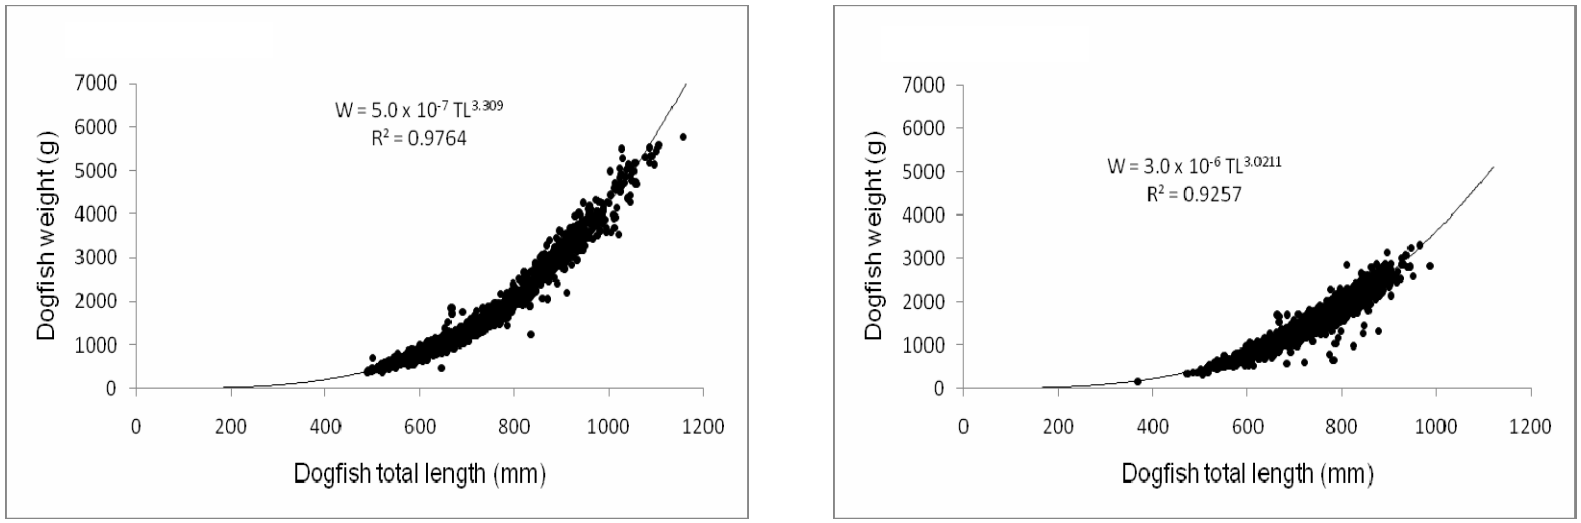

Figure 4. Relationship between weight (W) and total length (TL) for female and male spiny dogfish from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey. The equation for the regression lines is of the form $W = aTL^b$, and R^2 is the square of correlation coefficient.

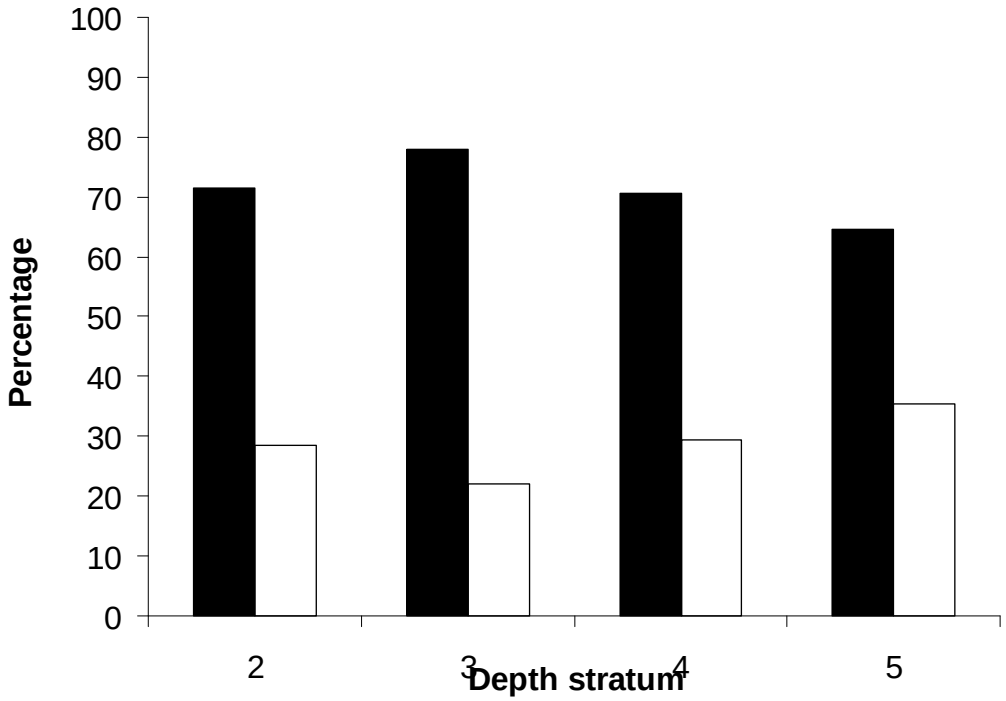

Figure 5. Spiny dogfish sex ratio by depth stratum (2: 56 to 110m, 3: 111 to 165m, 4: 166 to 220m and 5: deeper than 220m) from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey. Black bars are males; white bars are females.

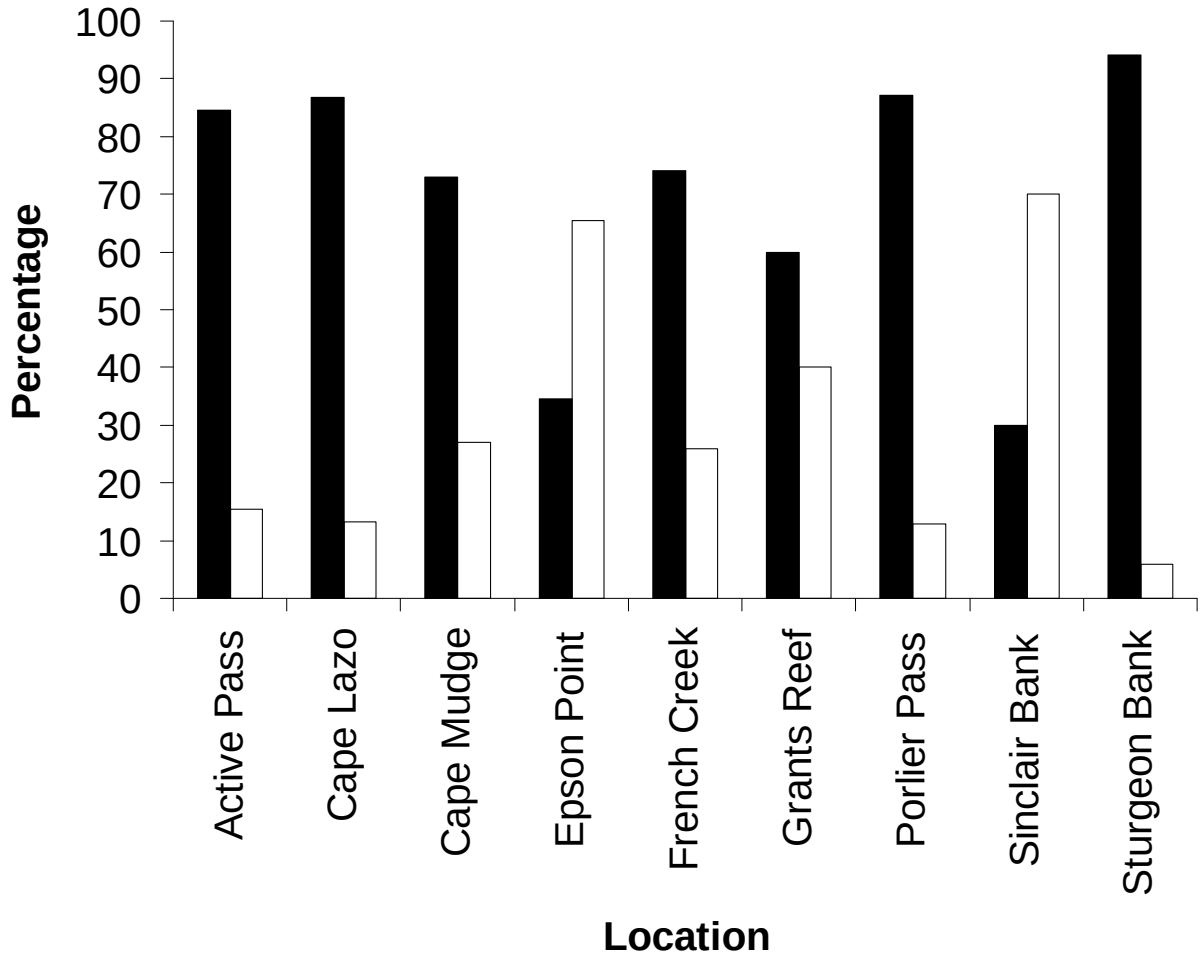

Figure 6. Spiny dogfish sex ratio by location from the October 7-15, 2011 Strait of Georgia spiny dogfish longline survey. Black bars are males; white bars are females.

Appendix 1. Bridge log from the October 5-17, 2011 spiny dogfish longline survey aboard the *CCGS Neocaligus*. Effective fishing time in minutes; all depths in meters; latitude and longitude in decimal degrees; distance in nautical miles; vessel speed in knots; direction in degrees true.
