

September 10 to 23, 2017 (Weeks 37-38)

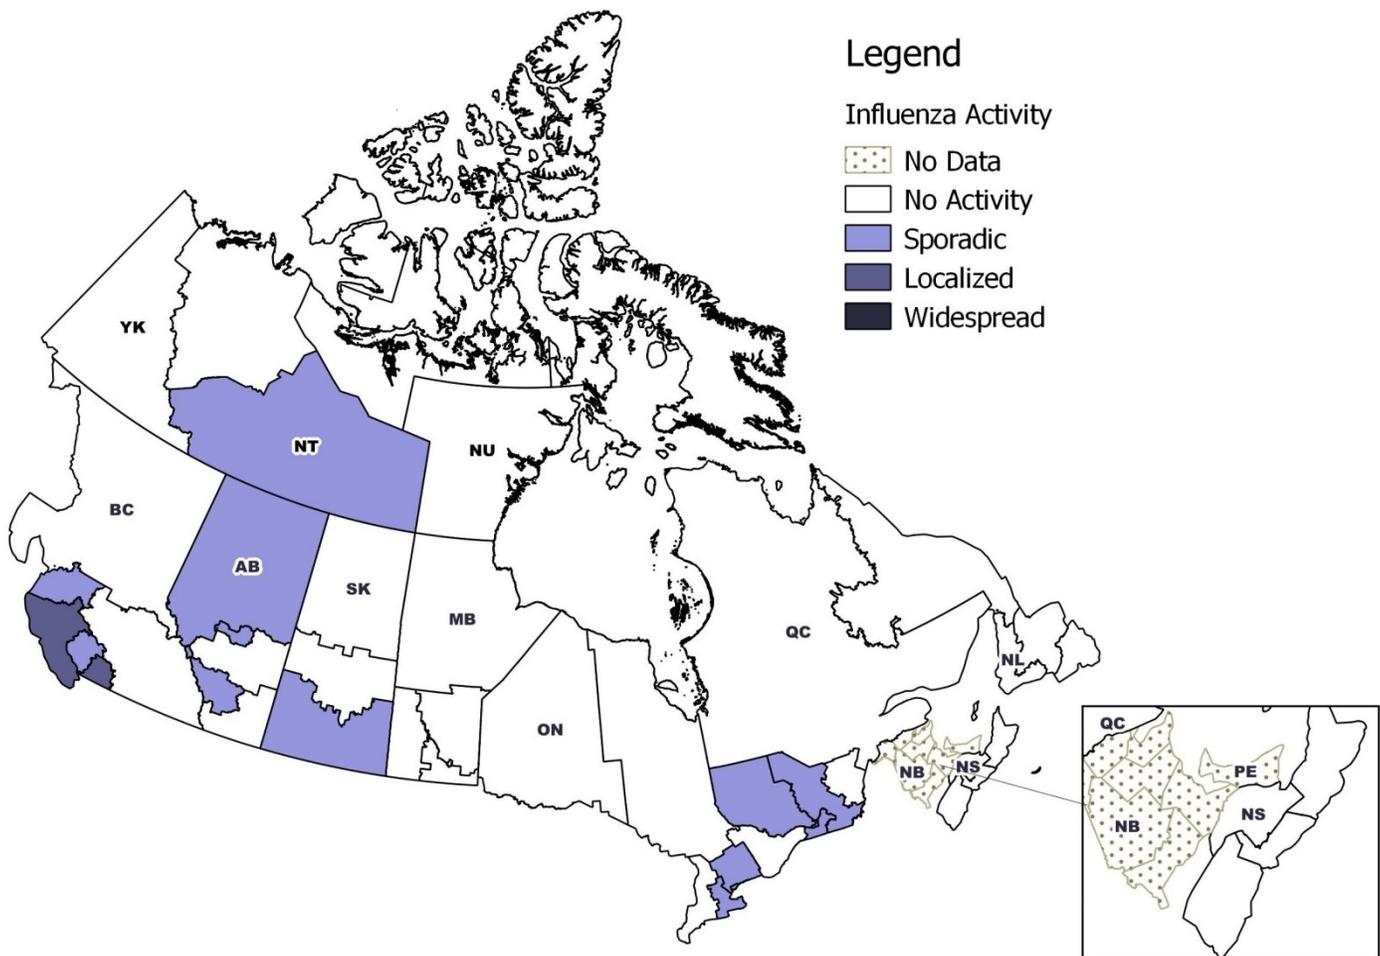

Overall Summary

- Influenza activity remains at interseasonal levels across the country. However, several indicators are above expected levels compared to previous seasons.
- In weeks 37-38, the majority of influenza detections continued to be A(H3N2). The percentage of laboratory tests positive for influenza is higher for this time of year compared to previous seasons.
- The next FluWatch report will be published on October 13th, 2017.
- For more information on the flu, see our [Flu\(influenza\)](#) web page.

Influenza/Influenza-like Illness (ILI) Activity (geographic spread)

In weeks 37-38, the majority of regions reported no influenza or influenza-like illness. In week 38, two regions in British Columbia reported localized activity, and 13 regions in British Columbia (1), Alberta (3), Saskatchewan (1), Ontario (3), Quebec (4) and Northwest Territories (1) reported sporadic activity. Consistent with the increased number of influenza detections this season, a greater number of regions are reporting sporadic activity compared to previous seasons.

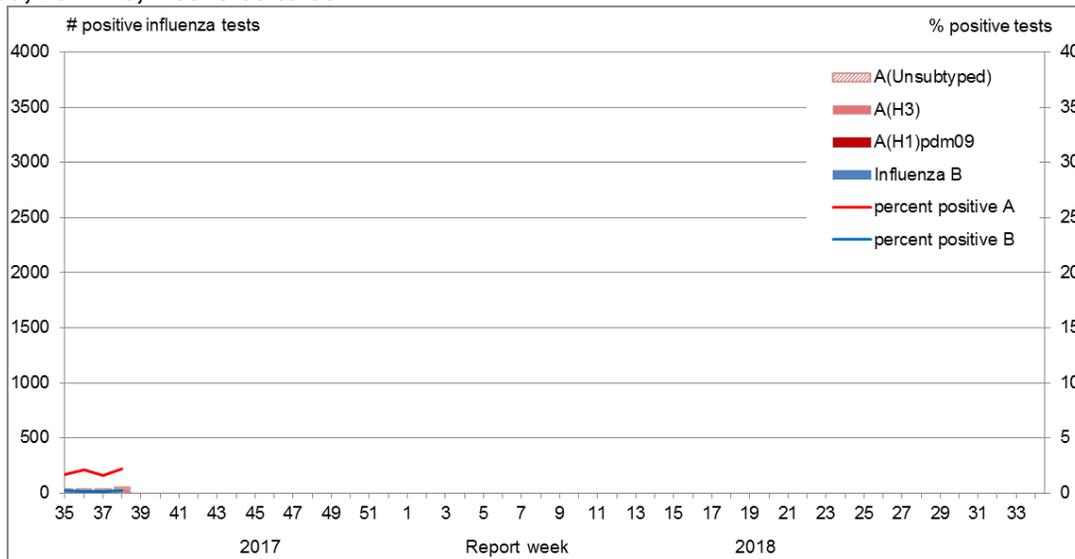

Figure 1 – Map of overall influenza/ILI activity level by province and territory, Canada, 2017-18, Week 38

Laboratory-Confirmed Influenza Detections

In weeks 37-38, the number of tests positive for influenza remained at interseasonal levels. The percentage of tests positive was low and remained at similar levels compared to the previous 2-week period (2.4% in week 38). The number and percentage of influenza A tests positive remains higher for this time of year than was observed during the previous seven seasons. Influenza B detections remain low and in keeping with previous seasons. For data on other respiratory virus detections, see the [Respiratory Virus Detections in Canada Report](#).

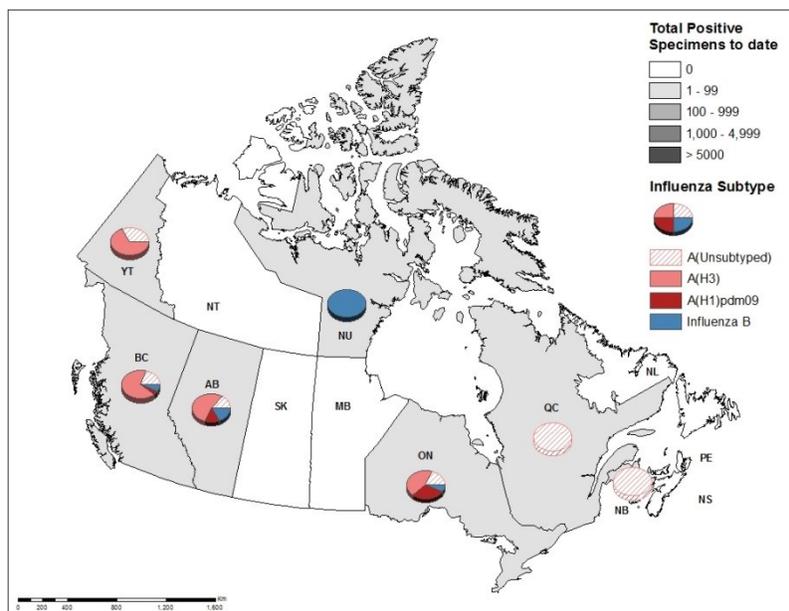

Figure 2 – Number of positive influenza tests and percentage of tests positive, by type, subtype and report week, Canada, 2017-18, weeks 35 to 38

The shaded area indicates weeks where the positivity rate was at least 5% and a minimum of 15 positive tests were observed, signalling the period of [seasonal influenza activity](#).

To date this season, 166 laboratory-confirmed influenza detections have been reported, of which 90% have been influenza A. Influenza A(H3N2) has been the most common subtype detected this season, representing 79% of subtyped influenza A detections. Detections from BC and AB represent 66% of the cases reported in this 2-week period, with a further 25% from Ontario. For more detailed weekly and cumulative influenza data, see the text descriptions for Figures 2 and 3 or the [Respiratory Virus Detections in Canada Report](#).

Figure 3 – Cumulative numbers of positive influenza specimens by type/subtype and province/territory, Canada, 2017-18, weeks 35 to 38

To date this season, detailed information on age and type/subtype has been received for more than 49 laboratory-confirmed influenza cases (Table 1). Based on the limited data to date, among influenza cases with reported age and type/subtype information, the majority of cases have been reported in adults aged 45-64 years of age (28%) and 65 years and older (43%).

Table 1 – Cumulative numbers of positive influenza specimens by type, subtype and age-group reported through case-based laboratory reporting, Canada, 2017-18, weeks 35 to 38

Age groups (years)	Cumulative (August 27 to September 23, 2017)						
	Influenza A				B	Influenza A and B	
	A Total	A(H1) pdm09	A(H3)	A (UnS) ¹	Total	#	%
0-4	6	<5	<5	0	<5	>6	7%
5-19	<5	<5	0	0	<5	5	4%
20-44	21	<5	14	<5	<5	>21	18%
45-64	31	9	11	11	<5	>33	28%
65+	49	<5	40	7	<5	>49	43%
Total	>107	21	>65	21	11	>118	100%

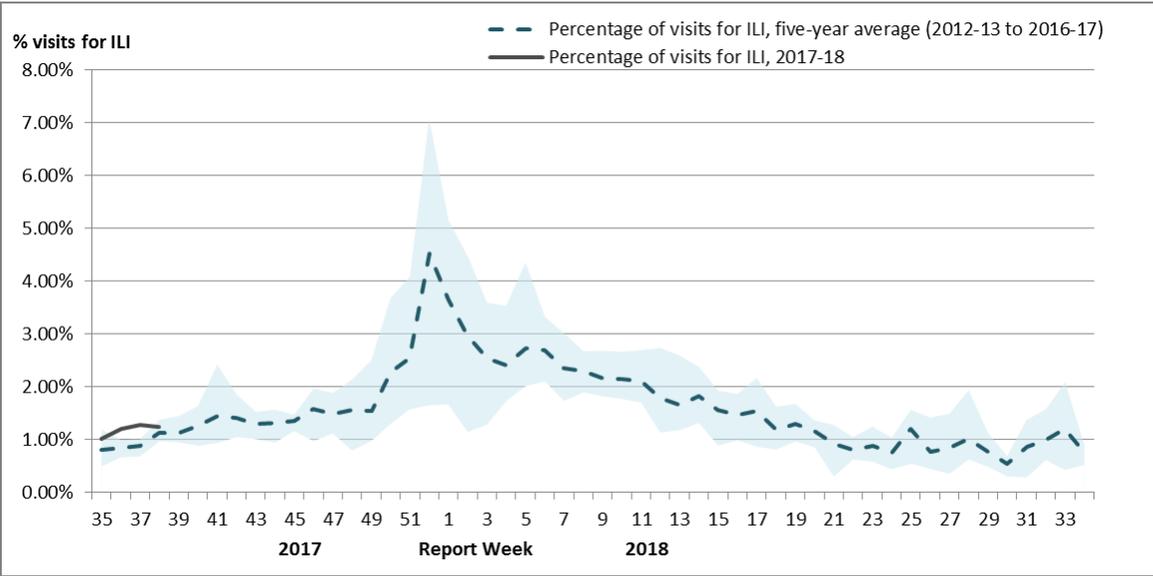

¹UnS: unsubtyped: The specimen was typed as influenza A, but no result for subtyping was available;
 x - Suppressed to prevent residual disclosure

Syndromic / Influenza-like Illness Surveillance

Healthcare Practitioners Sentinel Syndromic Surveillance

In week 38, 1.2% of visits to healthcare professionals were due to influenza-like illness, which follows the expected gradual increase for this time of year. The proportion of visits for ILI remains low, although it is higher than observed over the past five years.

Figure 4 – Percentage of visits for ILI reported by sentinels by report week, Canada, 2017-18, weeks 35 to 38
 Number of Sentinels Reporting in Week 38: 110

The shaded area represents the maximum and minimum percentage of visits for ILI reported by week from seasons 2012-13 to 2016-17

Participatory Syndromic Surveillance

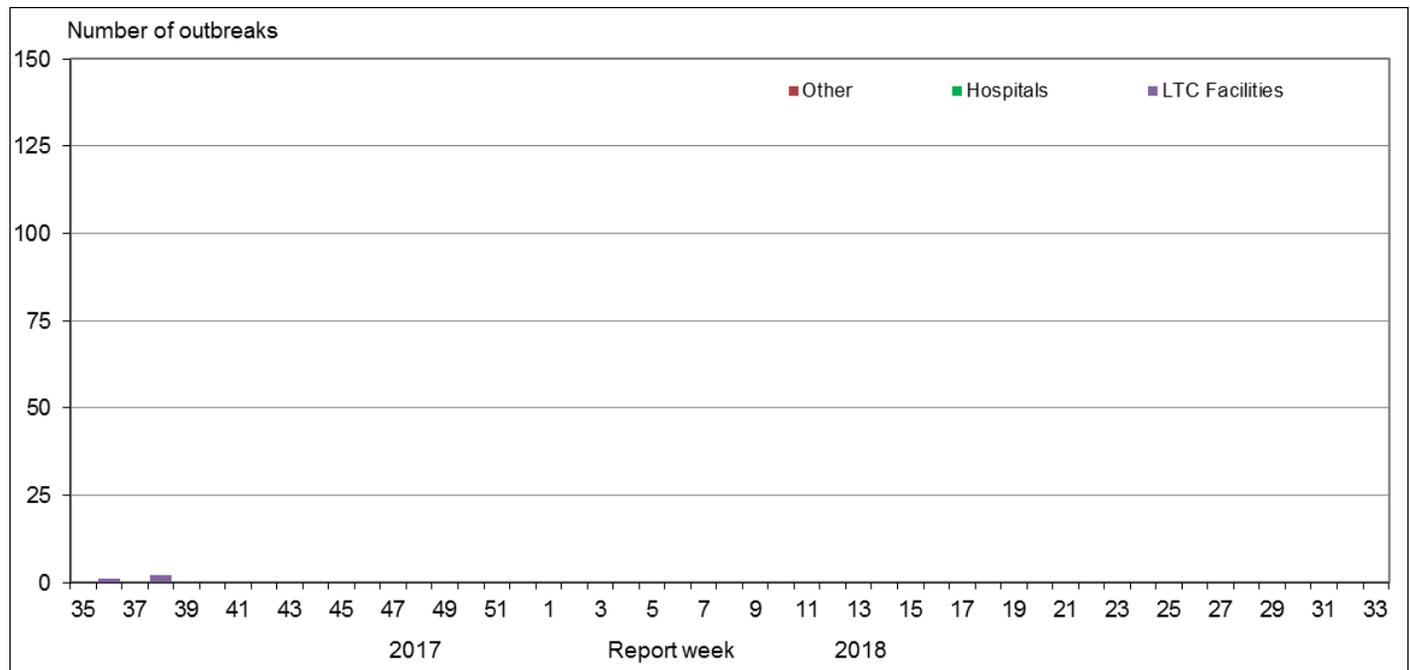

FluWatchers is a participatory ILI surveillance system that relies on weekly voluntary submissions of syndromic information from the Canadians across Canada.

The 2017-18 FluWatchers reporting season will begin October 1st, 2017 (week 40).

Influenza Outbreak Surveillance

In weeks 37-38, two new laboratory-confirmed influenza outbreaks were reported, both in long-term care facilities.

Figure 6 – Number of new outbreaks of laboratory-confirmed influenza by report week, Canada, 2017-18, weeks 35 to 38

Severe Outcomes Influenza Surveillance

Provincial/Territorial Influenza Hospitalizations and Deaths

To date this season, seven influenza-associated hospitalizations have been reported by participating provinces and territories¹, six of which were associated with influenza A, and all cases were adults 45 years of age or older.

¹Influenza-associated hospitalizations are reported by NL, PE, NS, NB, MB, AB, YT and NT. Only hospitalizations that require intensive medical care are reported by SK.

Pediatric Influenza Hospitalizations and Deaths

To date this season, less than five laboratory-confirmed influenza-associated pediatric (≤ 16 years of age) hospitalizations were reported from the Immunization Monitoring Program Active (IMPACT) network.

Influenza Strain Characterizations

During the 2017-18 influenza season, the National Microbiology Laboratory (NML) has characterized five influenza viruses [2 A(H3N2) were characterized genetically and 3 influenza B were characterized antigenically] that were received from Canadian laboratories.

Antigenic Characterization

Table 2 – Influenza antigenic strain characterizations, Canada, 2017-18 weeks 35-38

Strain Characterization Results	Count	Description
Influenza A (H3N2)		
A/Hong Kong/4801/2014-like	0	Viruses antigenically similar to A/Hong Kong/4801/2014, the A(H3N2) component of the 2017-18 Northern Hemisphere's trivalent and quadrivalent vaccine.
Influenza A (H1N1)		
A/Michigan/45/2015-like	0	Viruses antigenically similar to A/Michigan/45/2015, the A(H1N1) component of the 2017-18 Northern Hemisphere's trivalent and quadrivalent influenza vaccine.
Influenza B		
B/Brisbane/60/2008-like (Victoria lineage)	0	Viruses antigenically similar to B/Brisbane/60/2008, the influenza B component of the 2017-18 Northern Hemisphere's trivalent and quadrivalent influenza vaccine.
B/Phuket/3073/2013-like (Yamagata lineage)	3	Viruses antigenically similar to B/Phuket/3073/2013, the additional influenza B component of the 2017-18 Northern Hemisphere quadrivalent influenza vaccine.

Genetic Characterization of A(H3N2) viruses

During the 2017-18 season, two A(H3N2) viruses did not grow to sufficient titers for antigenic characterization by HI assay. Therefore, genetic characterization was performed to determine to which genetic group they belong. Both A(H3N2) viruses belonged to the same genetic group as the vaccine strain, A/Hong Kong/4801/2014 (group 3C.2a).

Antiviral Resistance

During the 2017-18 season, the National Microbiology Laboratory (NML) has tested five influenza viruses for resistance to oseltamivir and zanamivir, and all viruses were sensitive (Table 4).

Table 3 – Antiviral resistance by influenza virus type and subtype, Canada, 2017-18 weeks 35-38

Virus type and subtype	Oseltamivir		Zanamivir	
	# tested	# resistant (%)	# tested	# resistant (%)
A (H3N2)	2	0 (0%)	2	0 (0%)
A (H1N1)	0	0 (%)	0	0 (%)
B	3	0 (0%)	3	0 (0%)
TOTAL	5	0 (0%)	5	0 (0%)

Note: Since the 2009 pandemic, all circulating influenza A viruses have been resistant to amantadine, and it is therefore not currently recommended for use in the treatment of influenza. During the 2017-18 season, the subset of influenza A viruses that were tested for resistance to amantadine were resistant.

FluWatch Surveillance for the 2017-2018 Season – Notes and Definitions

The FluWatch report is compiled from a number of data sources. Surveillance information contained in this report is a reflection of the surveillance data available to FluWatch at the time of production. Delays in reporting of data may cause data to change retrospectively

Influenza/Influenza-like Illness (ILI) Activity

Influenza/ILI activity levels, as represented on the map, are assigned and reported by Provincial and Territorial Ministries of Health, based on laboratory confirmations, primary care consultations for ILI and reported outbreaks. ILI data may be reported through sentinel physicians, emergency room visits or health line telephone calls, and the determination of an increase is based on the assessment of the provincial/territorial epidemiologist. Maps from previous weeks, including any retrospective updates, are available in the mapping feature found in the [Weekly Influenza Reports](#).

Influenza/ILI Activity Level definitions

- 1 = No activity:** no laboratory-confirmed influenza detections in the reporting week, however, sporadically occurring ILI may be reported
- 2 = Sporadic:** sporadically occurring ILI and lab confirmed influenza detection(s) with **no outbreaks** detected within the influenza surveillance region†
- 3 = Localized:** (1) evidence of increased ILI* ; (2) lab confirmed influenza detection(s); (3) **outbreaks** in schools, hospitals, residential institutions and/or other types of facilities occurring in **less than 50% of the influenza surveillance region**†
- 4 = Widespread:** (1) evidence of increased ILI*; (2) lab confirmed influenza detection(s);(3) **outbreaks** in schools, hospitals, residential institutions and/or other types of facilities occurring **in greater than or equal to 50% of the influenza surveillance region**†;

* More than just sporadic as determined by the provincial/territorial epidemiologist.

†Influenza surveillance regions within the province or territory as defined by the provincial/territorial epidemiologist

Laboratory-Confirmed Influenza Detections

Provincial, regional and some hospital laboratories report the weekly number of tests and detections of influenza and other respiratory viruses. Provincial public health laboratories submit demographic information for cases of influenza. This case-level data represents a subset of influenza detections reported through aggregate reporting. Specimens from NT, YT, and NU are sent to reference laboratories in the provinces for testing.

Syndromic/Influenza-like Illness Surveillance

FluWatch maintains a network of primary care practitioners who report the weekly proportion of ILI cases seen in their practice. Independent sentinel networks in BC, AB, and SK compile their data for reporting to FluWatch. Not all sentinel physicians report every week.

Definition of Influenza-like-illness (ILI): Acute onset of respiratory illness with fever and cough and with one or more of the following - sore throat, arthralgia, myalgia, or prostration which is likely due to influenza. In children under 5 years of age, gastrointestinal symptoms may also be present. In patients under 5 or 65 years and older, fever may not be prominent.

Influenza Outbreak Surveillance

Outbreaks of influenza or ILI are reported from all provinces and territories, according to the definitions below. However, reporting of outbreaks of influenza/ILI from different types of facilities differs between jurisdictions. All provinces and territories with the exception of NU report influenza outbreaks in long-term care facilities. All provinces and territories with the exception of NU and QC report outbreaks in hospitals.

Outbreak definitions:

Schools: Greater than 10% absenteeism (or absenteeism that is higher (e.g. >5-10%) than expected level as determined by school or public health authority) which is likely due to ILI.

Hospitals and residential institutions: two or more cases of ILI within a seven-day period, including at least one laboratory-confirmed case of influenza. Residential institutions include but are not limited to long-term care facilities (LTCF) and prisons.

Workplace: Greater than 10% absenteeism on any day which is most likely due to ILI.

Other settings: two or more cases of ILI within a seven-day period, including at least one laboratory-confirmed case of influenza; i.e. closed communities.

Serious Outcome Influenza Surveillance

Provincial/Territorial Influenza Hospitalizations and Deaths

Influenza-associated hospitalizations and deaths are reported by 8 Provincial and Territorial Ministries of Health (excluding BC, NU, ON and QC). The hospitalization or death does not have to be attributable to influenza, a positive laboratory test is sufficient for reporting. Only hospitalizations that require intensive medical care are reported by SK.

Due to changes in participating provinces and territories, comparisons to previous years should be done with caution.

Pediatric Influenza Hospitalizations and Deaths

The Immunization Monitoring Program Active (IMPACT) network reports the weekly number of hospitalizations with influenza among children admitted to one of the 12 participating paediatric hospitals in 8 provinces. These represent a subset of all influenza-associated pediatric hospitalizations in Canada.

Influenza Strain Characterizations and Antiviral Resistance

Provincial public health laboratories send a subset of influenza virus isolates to the National Microbiology Laboratory for strain characterization and antiviral resistance. These represent a subset of all influenza detections in Canada and the proportion of isolates of each type and subtype is not necessarily representative of circulating viruses.

Antigenic strain characterization data reflect the results of hemagglutination inhibition (HI) testing compared to the reference influenza strains recommended by [WHO](#). Genetic strain characterization data are based on analysis of the sequence of the viral hemagglutinin (HA) gene.

Antiviral resistance testing is conducted by phenotypic and genotypic methods on influenza virus isolates submitted to the National Microbiology Laboratory. All isolates are tested for oseltamivir and zanamivir and a subset are tested for resistance to amantadine.
