This is the 94th Data Report
from the Central and Arctic Region

PREFACE

This study was funded by the Northern Oil and Gas Action Program (NOGAP), through the Department of Fisheries and Oceans, Central and Arctic Region. It is one of a series of projects executed under NOGAP B.2, to provide background data for assessing the implications of hydrocarbon development and production on critical estuarine and marine habitats of the Canadian Arctic Coastal Shelf. This document constitutes NOGAP Report B2.54.

ABSTRACT

Hopky, G.E., M.J. Lawrence, and D.B. Chiperzak. 1994. NOGAP B2; Data on the meio- and macrobenthos, and related bottom sediment from Tuktoyaktuk Harbour and Mason Bay, N.W.T., March, 1985 to 1988. Can. Data Rep. Fish. Aquat. Sci. 939: vi + 297 p.

Meio- and macrobenthos were collected from Tuktoyaktuk Harbour and Mason Bay in March, 1985 to 1988. Macrobenthos (500 µm sieve) were collected with a modified Van Veen sampler of 0.1 m² area. Sediment for analysis of meiobenthos (64 and 212 µm sieves) and macrobenthos (500 µm sieve) was sub-sampled from each Van Veen sample using a 15 cm long poly-vinyl carbonate core of 0.0017 m² cross-sectional area. A second core sub-sample was collected for sediment texture and total organic content analyses. In 1985, seven and six Van Veen samples were collected from Tuktoyaktuk Harbour and Mason Bay, respectively. In each of 1986 to 1988, for each bay, four Van Veen grabs were collected from the same six stations. Samples were collected from soft bottom substrate at depth strata of 4-6, 8-10, and >15 m, with two stations assigned per depth strata. Benthos abundance (number·m⁻²) and wet biomass (g·m⁻²) data are reported.

Key words: Arctic; Beaufort Sea; Tuktoyaktuk Harbour; Mason Bay; estuaries; marine; bays; meiobenthos; macrobenthos; abundance; biomass; interannual variation; sediment size; sediment organic content.

RÉSUMÉ

Hopky, G.E., M.J. Lawrence, and D.B. Chiperzak. 1994. NOGAP B2; Data on the meio- and macrobenthos, and related bottom sediment from Tuktoyaktuk Harbour and Mason Bay, N.W.T., March, 1985 to 1988. Can. Data Rep. Fish. Aquat. Sci. 939: vi + 297 p.

Au mois de mars, de 1985 à 1988, des échantillons de méiobenthos et de macrobenthos ont été recueillis dans le port de Tuktoyaktuk et dans la baie de Mason. Le macrobenthos (maille de 500 µm) a été recueilli à l'aide d'un échantilleur Van Veen modifié de 0.1 m² de superficie. Les sédiments destinés à l'analyse du méiobenthos (maille de 64 et 212 µm) et du macrobenthos (maille de 500 µm) ont fait l'objet d'un sous-échantillonnage; à cette fin, on a prélevé une carotte dans chaque échantillon Van Veen l'aide d'un tube de poly (carbonate de vinyle) de 15 cm de long et de 0.0017 m² de section. Une deuxième carotte de sous-échantillonnage a été prélevée pour l'analyse de la texture des sédiments et de leur contenu organique total. En 1985, sept et six échantillons de type Van Veen ont été recueillis respectivement dans le port de Tuktoyaktuk et dans la baie de Mason. Chaque année, de 1986 à 1988, quatre échantillons ont été prélevés au hasard dans chacune des deux baies dans les mêmes six stations. Les échantillons ont été extraits du substrat meuble à différentes profondeurs: 4-6 m, 8-10 m et plus de 15 m, à raison de deux stations par strate de profondeur. On présente les données sur l'abondance du benthos (nombre par m²) et la biomasse humide (g par m²).

Mots-clés: Arctique; mer de Beaufort; port de Tuktoyaktuk; baie de Mason; estuaries; marine; baies; méiobenthos; macrobenthos; abondance; biomasse; variation annuelle; teneur en matières organiques des sédiments.

INTRODUCTION

The biological and physical data presented in this report were collected as part of the Nearshore Benthic Monitoring Subproject (B.2.3). This sub-project is one component of the Critical Estuarine and Marine Habitat Project (B.2) of the Northern Oil and Gas Action Program (NOGAP). Project B.2 is a multi-disciplinary study of the Canadian Arctic coastal shelf undertaken by staff of the Department of Fisheries and Oceans (DFO). The Project goal is to provide background data for assessing the implications of hydrocarbon development and production on fish and fish habitat of Arctic estuarine and marine environments, including coastal bays of the Canadian Beaufort Sea (Fig. 1).

Subproject B.2.3's contribution to this goal is to provide baseline biological data on benthic invertebrate populations found in typical "fiord-type" bays along the Beaufort Sea coast. Although coastal bays are often characterized by restricted water circulation with adjacent shelf waters (Barber 1968), they provide critical habitat for estuarine, marine and freshwater fish (e.g. Bond 1982; Lawrence et al. 1984; Hopky and Ratynski 1984). As such, the fish habitat in these bays is particularly important with respect to potential impacts from development activities, such as dredging to provide access for support vessels (Thomas et al. 1981). Monitoring for potential impacts on fish habitat are of limited value without pre-development baseline data, such as the extent of background variation inherent in the parameter selected for monitoring. This baseline data requirement, and the need for basic ecological research on benthic communities in nearshore estuarine environments of the Beaufort Sea and Mackenzie River estuary, were deficiencies identified by the Beaufort Environmental Assessment and Review Panel (FEARO 1984). Historically, studies of benthic communities in the southeastern Beaufort Sea have been synoptic surveys that were limited in either time or space, or limited in scope or purpose, typically to assess potential impacts of a specific project (Wainwright et al. 1987).

The Nearshore Benthic Monitoring Subproject was undertaken to provide a basis for determining the feasibility of practical, cost-effective programs for monitoring the effects of development activities

on benthic communities in coastal bays. The Subproject objectives are:

1. to characterize the meiobenthic and macrobenthic communities, to determine the extent of interannual variability in numbers and biomass of these communities, and to relate these results to chemical and physical attributes in the sediment and water column; and
2. to develop sampling and analysis methods and to evaluate approaches for future effects-monitoring programs.

In this report, data on meio- and macrobenthic community abundance and wet biomass, and sediment texture, size distribution and total organic content are presented. Water column salinity, temperature and density data are found in Hopky et al. (1990), and related water column chemical data (e.g. nutrients, pH, dissolved oxygen, chlorophyll *a*, etc.) are found in Lawrence et al. (1993). Water column light extinction and photofluorometric data were also collected (Hopky et al. 1994a). In addition, invertebrate specimens collected from this study have resulted in, or contributed to increased understanding of the taxonomy and distribution of benthic invertebrates (Korcynski 1989; Higgins and Korczynski 1989; Keast and Lawrence 1990) in the Beaufort Sea region.

Field research for Subproject B.2.3 was conducted in March of 1985 to 1988. Results from a preliminary survey in March of 1985 led to a redefinition of study design. Tuktoyaktuk Harbour, north basin (Fig. 2), and Mason Bay (Fig. 3) were selected as sites for subsequent study. Sampling was conducted during the ice-cover period (March) to minimize potential variability associated with benthic life history population dynamics (e.g. larval settling) and oceanographic effects (e.g. wave turbulence) that are more prevalent during the open water season. Station locations were stratified by depth as a function of water column salinity gradient, and gently sloped sites with greater than a 90% silt-clay sediment bottom type were selected.

METHODS

STUDY AREA

Tuktoyaktuk Harbour, N.W.T.

Tuktoyaktuk Harbour, located at 69°26'N, 132°59'W, is on the eastern edge of the Mackenzie River delta (Fig. 1). It is 6.5 km long and up to 1.8 km wide (Fig. 2) with a total surface area of 942 ha, and has two distinct basins divided by a shallow 5 m sill (Thomas et al. 1981). Depths greater than 20 m occur in both basins, with depths in excess of 10 m accounting for 44% and 55% of the north and south basin surface areas, respectively. Maximum depth is 26 m. The bottom sediment is predominantly silt-clay (Thomas et al. 1981; Bond 1982).

Two narrow channels at the harbour mouth maintain a seaward connection to Kugmallit Bay. The bay is shallow, with depths of 5 m not exceeded within 10 km from the harbour mouth. Consequently, exchange of water between Kugmallit Bay and Tuktoyaktuk Harbour takes place through the upper 4-5 m of the water column (Barber 1968). The channels were deepened from 2 m to a depth of 4-5 m in 1981 to allow for entry of deeper draft vessels into the harbour. Three freshwater creeks also drain into the harbour on a seasonal basis.

During the ice-free period, when north and west winds predominate, Kugmallit Bay water column profiles exhibit low salinities which are associated with a large freshwater input from the Mackenzie River (Parsons et al. 1989; Hopky et al. 1987). When winds have south and east components, marine upwellings occur, often bringing cold saline water from the deeper Beaufort Sea basin into nearshore areas. Thus the mouth of Tuktoyaktuk Harbour is alternately exposed to high, medium and low saline waters during the ice-free period. As a result, during open water the upper water layer within the harbour becomes more mixed than during ice cover (Barber 1968). The mixed surface layer may extend as deep as 9-10 m by the end of August. Salinities of 12 to 15 and temperatures up to 15°C occur in the upper water layer at this time. Dissolved oxygen is usually at near saturation values. Below the pycnocline, salinities increase to 29 to 31 with minimum temperatures of 0-1°C.

Lunar tides in the harbour fluctuate 0.3-0.4 m. Depending upon direction, winds can increase or decrease water levels in the harbour as much as a meter for extended periods of time.

During the period of ice cover (October-late June) an upper, freshwater layer stabilizes and develops to a maximum depth of approximately 6 m by spring (Hopky et al. 1990). The freshwater originates from the Mackenzie River system (Barber 1968; Hopky et al. 1987).

Mason Bay, N.W.T.

Mason Bay, located at 69°33'N, 134°06'W, is on the northeastern coast of Richards Island in the Mackenzie River delta (Fig. 1). It is 9 km wide (east-west) and 7.5 km long, with a total surface area of 4080 ha (Fig. 3). Reconnaissance level hydrographic surveys performed in 1964 show maximum depths of 24 m, with depths in excess of 10 m accounting for approximately one-half of the surface area. Wacasey et al. (1977) reported a maximum depth of 26 m and described the bottom substrate as being predominantly silt-clay with variable amounts of sand.

Two shallow (2 m deep or less) channels, unaltered by industrial activity, maintain a seaward connection with Kugmallit Bay. Consequently, exchange of water during the open water season takes place through the upper few metres and during winter exchange is minimal, or may cease as ice accretes into the sediments. An uncharted channel connects Mason Bay to an adjacent bay with similar morphometry, that is also connected to Kugmallit Bay by a shallow channel.

During the open water season, satellite imagery confirms that there is exchange of water between Mason Bay and Kugmallit Bay, the extent of which depends upon wind speed and direction. As in Tuktoyaktuk Harbour, the normal tidal range is small. Local drainage into Mason Bay is seasonal and comes predominantly from two small drainages located on the southern shore of the bay (Lawrence et al. 1984).

During the period of ice cover (October-late June), water column conditions remain stable. Measurements taken during March, 1986 to 1988, suggest a progressive cooling of the upper freshwater layer, which is underlain by more saline,

warmer water (Hopky et al. 1990).

STATIONS AND POSITIONING

Station locations for 1985 to 1988 are shown in Tables 1 to 4, respectively, and illustrated in Figs. 4 and 5 for Tuktoyaktuk Harbour and Mason Bay, respectively. Stations were assigned an alpha-numeric code name. Station names designated with a "T" are for Tuktoyaktuk Harbour stations, while those with an "M" are Mason Bay stations.

In March, 1985, Tuktoyaktuk Harbour was sampled by use of trucks and a tracked vehicle equipped with a 45.7 cm diameter gas-powered auger. Stations were located by reference to bathymetric charts and visual triangulation to known landmarks. This was facilitated by both the harbour shape (Fig. 2) and extensive shoreline industrial development. No estimates of station positioning error were made, but were probably on the order of ± 0.2 km. Mason Bay was accessed by a chartered Twin Otter (DH6) aircraft in March, 1985, while power toboggans were used on the ice surface to transport personnel, equipment and a sled-mounted 45.7 cm gas-powered auger. Station locations were estimated using the same methods as employed for Tuktoyaktuk Harbour.

In March of 1986 to 1988 all stations in Tuktoyaktuk Harbour and Mason Bay were sampled from an on site, skid-mounted laboratory attached to a completely self contained mobile field camp. Stations were established as follows. For each bay, two stations were randomly established within each of three depth strata: 4-6, 8-10 and >15 m. Station locations selected had predominantly silt-clay substrate with uniform bottom slope. Once established in 1986, the stations were returned to for sampling in 1987 and 1988. To minimize the degree of inter-annual re-positioning error, an infrared rangefinding system (Sokkisha Red Model 2 L), in conjunction with a theodolite (Wild TI 70 Series), was used as follows. In 1986 stakes were located at known locations along the shoreline of both bays (Figs. 2 and 3). Tripod-mounted triple prism light-reflecting targets (to reflect the rangefinder's infrared signal) were positioned at two of the stake locations closest to the general area of the prospective station. Station positions were first established by trial and error

without aid of the rangefinder, and located within specified depth strata. The rangefinder and theodolite were then used to determine station-to-target distances and the angle between targets, respectively (Table 5). This estimate of station location is referred to as the "pin location". In 1987 and 1988 the triple prism targets were repositioned at the shoreline stake locations. Pin locations were then relocated by an iterative process - a series of intermediate "instrument locations" - until the station-specific angles and distances measured in 1986 were approximately achieved (Table 5).

There are several possible error sources in this positioning procedure. Instrument error in the rangefinder was minimized by annual calibration, and rangefinder error due to repeated measurements of the same target was insignificant (<1 mm). Measurement error resulting from imprecise instrument adjustment for ambient temperature and pressure conditions did not exceed 2 cm.

The estimated error in repositioning of the targets in 1987 and 1988, relative to 1986, is shown in Table 6. In one case the stake for a target location (T2) had been removed, and the target location approximated and repositioned through reference to nearby landmarks. Other sources of variability in repositioning of the targets were due largely to differences in prevailing snow conditions from one year to the next making it difficult to precisely reposition the target in the dense, deep snow-pack.

There were also errors introduced as a result of varying degrees of interpolation or extrapolation required to determine pin location based upon final instrument location. In most cases pin location was within a "step-or-two" of the final instrument location (Table 5). For all intents and purposes, these two locations are the same. Exceptions to this "step-or-two" positioning protocol are noted in Table 5 where the required distance adjustments to final instrument locations are shown in parenthesis. These distance adjustments were made either toward (-) or away (+) from the relevant target to determine pin location.

In three instances target-to-instrument distances exceeded the rangefinder capability due to heavy atmospheric ice crystal haze. In these instances the inter-target angle in combination with one target-to-instrument distance was used.

Subsequently, the missing distance value was back-calculated to provide verification (Table 5) of the final instrument (and pin) location. The absence of measured inter-target angles in five instances (Table 5) does not affect the precision of repositioning, however, independent verification of final instrument locations are not possible.

All of the above error sources were combined to estimate an overall pin location error for each station. The boundary of this error estimate is represented by the non-hatched polygons shown in Figs. 6 and 7, for each permanent station in Tuktoyaktuk Harbour and Mason Bay, respectively. In most cases estimated pin locations for each station fall within a ± 5 m radius. Station coordinates were determined by first plotting target locations on a 1:50000 scale NTS topographic map for Mason Bay, or a 1:15000 scale hydrographic chart for Tuktoyaktuk Harbour. Plotting of target locations was based upon knowledge of nearby landmarks and proximity to them. Then target-to-pin location distances (Table 5) were used to "triangulate" pin locations on the map or chart. Latitude and longitude were then determined from the map or chart with the aid of dividers.

SAMPLE COLLECTION AND FIELD PROCESSING

In 1985 one Van Veen grab (opened mouth dimensions = 0.32×0.32 m; grab area = 0.1 m^2) sample per station (Table 1) was collected. At station 85M05 a second grab was made from the same hole used for the first grab, as the first grab was discarded due to insufficient sediment volume in the grab. For each grab sample, poly-vinyl carbonate core tubes (15×4.71 cm inner diameter; with a cross-sectional area of 0.0017 m^2) were used to extract two core sub-samples from opposite sides of, and immediately adjacent to the Van Veen's centre brace. Both cores were frozen and not thawed until processed in Winnipeg. The grab contents were then scraped and rinsed into 22 L pails. All sampling was conducted in the open, with sample sediment often freezing to the grab under the extreme weather conditions.

The Van Veen samples were later processed at the DFO base camp in Tuktoyaktuk, up to 12-18 hrs after sampling. Sediment grab volume was estimated and the sample then sieved through a

Nitex screen with mesh size of $500 \mu\text{m}$ using domestic fresh water. Material retained on the sieve was then rinsed into a jar and fixed in a 5% solution of formalin, and protected from freezing. Samples were further processed in Winnipeg.

In each of 1986 to 1988, four Van Veen grab samples per station were made, with all samples processed on-site. This maximized sample quality and increased sampling efficiency. At each station a modified ice-hole melter (Arctic Laboratories Ltd. 1985) was used to melt two sampling holes (1.2×0.5 m), randomly spaced between 1.2-7.3 m apart. The mobile laboratory trailer was then moved over the first hole and a protective sleeve lowered to the ice surface. The Van Veen grab was lowered down along the 0.5 m side of the hole and a sample taken. Once retrieved, sample volume was estimated by measuring depth of sediment in the grab and use of a calibrated relationship between grab sediment depth and grab volume. Each sample was visually inspected for any apparent disturbance resulting from a poorly executed grab. Poly-vinyl carbonate core tubes were used, as described above, to extract two core sub-samples. Contents of the first core were rinsed with *in situ* water into a glass jar and sufficient formaldehyde and water added to produce a 5% solution of fixative. Contents of the second core were immediately frozen for subsequent determination of particle size distribution and total organic content. Core sub-samples were further processed in Winnipeg. After core sampling, the Van Veen grab contents were rinsed into a plastic tub using *in situ* un-filtered water.

This sampling sequence was then repeated on the opposite (0.5 m) side of the first hole to collect the second Van Veen and related core sub-samples. Van Veen grab samples three and four, and corresponding core sub-samples were then collected from the second hole in the same way.

Field processing of each grab began within 1-3 hrs after collection, and only after all grabs for a station had been collected. The contents in a plastic tub were placed in a box (0.7 m square) with a bottom of Nitex screen, and mesh size of $500 \mu\text{m}$, and washed with *in situ* un-filtered water until there was no evidence of mud substrate remaining. Material retained on the sieve was then rinsed into a jar, fixed in a 5% solution of formaldehyde, and protected from freezing. This process was then

repeated for each of the three remaining samples. Samples were further processed in Winnipeg.

The sequence of grab sample collection (designated as station sample numbers 1 to 4) was recorded, and distance between the two holes, and thus the grab sample locations, relative to the pin location was measured for each station. Combined with the error estimate for pin location, locations of grab samples in 1986 to 1988 were estimated. Boundaries of these estimates are represented by the hatched areas shown in Figs. 6 and 7. Given that, for any station within sample year, distances (m) between grab pairs within a hole (i.e. samples 1 to 2, or 3 to 4), and between the holes, are fixed, what the hatched areas illustrate are estimated locations of grabs in one year relative to those in other years.

SAMPLE PROCESSING AND REPORTING

All samples were processed using contract services, with the biological and physical sediment analyses done by different laboratories.

Specimen identification and abundance

Level of taxonomy and data coding: Specimens were identified with the aid of reference texts, keys and collections, and verified as required. All specimens were assigned numeric codes based on a catalogue and systematic list developed for this and a related NOGAP Subproject, B.2.1. Details regarding identifications, the systematic list and catalogue code are described elsewhere (Hopky et al. 1994b). To aid in data processing and subsequent analysis major taxonomic groups were identified (Table A1.1, Appendix A1). With the exception of certain miscellaneous groups (e.g. "940000 Stones, pebbles") taxonomic groups used in the benthic studies represented higher systematic levels (phylum, class, order and suborder).

All organisms, with the exception of those from the Foraminiferida, Nematoda and Ostracoda taxonomic groups, were identified to species level whenever possible, unless the organism was damaged and could not be identified. For 1985 samples, attempts were made to identify foraminiferans to the lowest level possible, but for 1986 to 1988 samples they were identified as Foraminiferida, only. The Nematoda were identified as such for all

sample years. All ostracods in the 1985 samples were identified to the lowest level possible. The level of identification of ostracods in the 1986 to 1988 samples varied between years and sample types, with details given in the subsequent subsections. Species level identification of larval stages found in 64 and 212 µm core fractions was often impossible due to the lack of development and differentiation in the specimen.

Specimens were often distinguished by life history stage or integrity (i.e. whole, fragment, etc.). This and related information was coded, and Table 7 identifies the codes used. For colonial organisms, the Hydrozoa, Bryozoa and Entoprocta, counts of colony numbers were made only when a complete, intact colony was recovered; otherwise the presence of colony fragments was noted. When statoblasts were identified they were either counted, or presence noted. The presence of empty tubes (whole or fragments) for the Polychaeta group was noted, and occasionally they were counted, but only if an intact tube could be identified to species level. Dead ostracods and one-half shells in all samples were distinguished from live ones. In the 1985 samples dead ostracods and one-half shells were recorded as present/absent only, while in 1986 to 1988 samples their numbers were counted. In all samples live ostracods were counted. Specimens of gastropods and bivalves were distinguished as live or dead, and life history stage occasionally noted. Valve or shell fragments were noted as present only, except when single specimens at the species level could be identified. Adult and juvenile stages were noted for specimens from the Priapulida, Cumacea, Isopoda, Amphipoda and Decapoda taxonomic groups. However, for 1985 samples Amphipoda specimens were not distinguished by life history stage. Specimens of Copepoda species were differentiated where possible as adults and copepodites. Harpacticoid copepods from core sub-samples were generally identified only as such, due to difficulty with their identification. For taxonomic groups where the comment "fragment" (comment code = 39, Table 7) was used, presence only was noted; except when single specimens could be identified to species, then the number of specimens counted was recorded. Because of their small size, in some samples whole (i.e. not a fragment) specimens from the Kinorhyncha group were not counted but their present noted.

Van Veen grab samples: All samples were received in the laboratory in 5% formalin. The 1985 samples were transferred to 70% alcohol and sieved through either 500 or 425 μm screens.

Once in the laboratory Rose Bengal was added to all samples collected in 1987 and 1988. The sample was allowed to sit for a few days, which improved dye uptake by the organisms. This facilitated the speed of sorting, especially for nematodes, but did not affect specimen identification or numbers counted. All 1986, 1987 and 1988 samples were then rinsed under tap water over a 500 μm Endicott screen until the presence of formalin was undetectable.

All samples were processed using the naked eye and compound microscopes. Taxonomists, assigned to the task of identification and counting of specific taxonomic groups, continued with the task until all samples were processed. Methods used to count and identify 1985 samples differed from those used for 1986 to 1988 samples.

For the 1985 samples, a sample was first placed in a white sorting tray. If there was little or no vegetative or particulate matter then all specimens in the sample were identified and counted, with no splitting required; otherwise, the vegetative and particulate fractions were removed and stored. Visible specimens remaining in the tray were removed, identified and all were counted. If the total number of specimens in the particulate fraction was estimated to exceed 300 then the fraction was agitated and split using a two chamber Folsom splitter. Splits were conducted until about 10% of the total estimated number of organisms were identified and counted. Total numbers were then calculated by extrapolation using the split fraction value. The vegetative fraction was "split" by randomly sub-sampling aliquots of vegetation of different weights. All specimens in each aliquot were then counted and identified until at least 10% of the total weight of the vegetative fraction was processed. Total numbers were calculated by extrapolation using the fraction of weight of vegetation sub-sampled compared to total vegetation weight.

For the 1986 to 1988 samples, a rinsed sample was first placed in a white enamel tray, and vegetation was rinsed, removed and stored. All organisms, other than ostracods, nematodes,

foraminiferans and in some instances taxonomic groups (e.g. gastropods) estimated to be present in quantities greater than 1000 organisms, were removed from the tray and sorted into taxonomic groups with the groups preserved in 70% alcohol.

Specimens in taxonomic groups removed from the tray were counted and identified as follows. When a taxonomic group contained 100 or less organisms all were counted and identified. If the group contained between 101 and 1000 organisms a random sub-sample of 100 was made, all specimens counted and identified, with the balance counted to estimate total number in the sample. Identifications of the balance were assigned by extrapolation from the random sub-sample.

The sample remaining in the tray was split using a two chamber Folsom splitter. Splits were conducted until a sub-sample containing 500 ($\pm 10\%$) organisms was obtained. From this sub-sample, 100 each of the live ostracods, foraminiferans and nematodes were removed and stored in separate vials. The 100 live ostracods were counted and identified to family level. For 1988 samples dead and one-half shell ostracods were also identified to the family level, if possible; whereas in the 1986 and 1987 samples these ostracod specimens were identified as Ostracoda, only. All ostracods (i.e. live, dead, and one-half shells), foraminiferans and nematodes remaining in the sub-sample were counted, with the live ostracod number apportioned according to identifications from the group of 100 specimens. Total numbers for the sample were then estimated by extrapolation using the split fraction value.

Core sub-samples: The 1985 core sub-samples were received in the laboratory in frozen condition. Of the two cores collected from each station, one was cut in half longitudinally, thawed, dried at 70-80°C and used for sediment textural and organic content analyses, described below. The remaining half cores and all second cores were thawed and re-hydrated with a 70% alcohol solution. Each was then sieved sequentially through 500 and 212 μm screens by gentle washing with tap water. All organisms were counted and identified. Samples from the 500 μm fractions were processed with the naked eye and a compound microscope, while the 212 μm fractions were processed with a compound micro-

scope. Splitting was required only once, for determining the number of ostracods and foraminiferans in a 212 μm fraction sample. Methods for splitting are as described below for the 1986 to 1988 212 μm fraction samples.

The 1986 to 1988 core sub-samples were received in the laboratory in 5% formalin solution. Each sample was then separated into size fractions by sequentially sieving through a series of 500, 212 and 64 μm screens, and each fraction preserved separately in 70% alcohol for further analysis. Samples from the 500 μm fractions were processed with the naked eye and a compound microscope, while all the 212 and 64 μm fractions were processed with a compound microscope.

All 500 μm fraction samples contained less than 1000 organisms, so it was more efficient to process the entire sample than to sub-sample. Vegetation was rinsed, removed and stored. All organisms other than ostracods, foraminiferans and nematodes were removed, and stored in taxonomic group-specific vials. When a taxonomic group contained 100 or less organisms all were counted and identified. If the group contained between 101 and 1000 organisms a random sub-sample of 100 was made, its specimens counted and identified, and the remaining ones were counted for the purpose of extrapolation to estimate total number in the sample. Identifications for these remaining ones were based on extrapolation from the identifications assigned those in the random sub-sample. One hundred of each of the live ostracods, foraminiferans and nematodes were removed and stored in separate vials. The 100 live ostracods were counted and identified to family level. For 1988 samples dead and one-half shell ostracods were also identified to the family level, if possible; whereas in the 1986 and 1987 samples these ostracod specimens were identified as Ostracoda, only. All ostracods (i.e. live, dead, and one-half shells), foraminiferans and nematodes remaining were counted, with the live ostracod number apportioned according to identifications made on the group of 100 specimens.

The 212 μm fraction samples contained relatively large numbers of organisms and sub-sampling with a Folsom splitter was often required. They were processed in the same manner as the Van Veen grab samples, except that: a) vegetation was not removed from the tray; b) if the

sample remaining in the tray contained less than 1000 organisms, rather than splitting, all remaining organisms (i.e. foraminiferans, nematodes, live and dead ostracods and one-half ostracod shells) were counted and re-preserved in 70% alcohol; c) when there were more than 1000 organisms remaining on the tray splitting was done, but all organisms (i.e. nematodes, foraminiferans and ostracods) in the split sub-sample were counted, and the entire sample re-preserved in 70% alcohol; and d) because wet weight determinations were not made for the 212 μm cores, lots of 100 specimens for each of the nematode, foraminiferan and ostracod groups remaining in the tray were not set aside. Only live ostracods from the 1986 samples were identified to family level, if possible; while all other ostracod specimens were identified as Ostracoda.

The 64 μm fraction samples represented the highest level of difficulty associated with any of the samples processed. This was caused by the presence of large quantities of extremely fine organic and inorganic particles, and the very small size of the organisms. The first few samples processed in 1986 were sorted in the same fashion as the 212 μm core sub-samples. Very few organisms other than nematodes, foraminiferans and ostracods were found, and as processing time was excessive, the following method was employed for all remaining samples. An aliquot of the sample was placed under a microscope and the total number of organisms estimated. The sample was then split until approximately 500 ($\pm 10\%$) organisms were present in the sub-sample. In a few cases extremely high quantities of fine material caused the samples to be split to the point where sub-samples contained less than 500 organisms. Ostracods, nematodes and foraminiferans in the sub-sample were counted and not removed. Tintinids (protozoans) were present in all sub-samples and their presence noted as such. Other organisms were removed from the sub-sample, sorted to taxonomic group level, and all were identified and counted. Only live ostracods from the 1986 samples were identified to family level, if possible; while all other ostracod specimens were identified as Ostracoda. Total numbers in the fraction were estimated by extrapolation.

Organisms removed from the 64 μm fraction sample were not visible to the naked eye which made handling difficult. The sorter was therefore required to write the type of specimen and quantity

present on the label, for example "priapulid larva - 1". In some cases, the organism(s) could not be found by the taxonomist, and the information recorded by the sorter was used instead.

Sample wet biomass

Wet sample weights for the 1986 to 1988 Van Veen and 500 µm core fraction samples were estimated by summing the weights measured on each of the taxonomic groups present in a sample. Wet weight of each group was measured to the nearest 0.001 g using a Mettler, PM100 microbalance. In most cases the number weighed for each taxonomic group represented the total number of that group's specimens in a sample, otherwise sub-samples (e.g. such as the 100 specimen sample of live ostracods) were weighed, and taxonomic group sample weight estimated by extrapolation. Depending on the taxonomic group, fragments of organisms were either weighed together with whole organisms, or separately (e.g. polychaetes). Ostracod half shells and dead ostracods were weighed only for 1988 samples, while live ostracods were weighed in all sample years. Nematodes were not weighed in 1986 and 1987, and rarely in 1988 due to the difficulty associated with handling such small organisms. Live and dead specimens from each of the bivalve and gastropod groups were weighed and recorded separately. However, in some cases, particularly for the 1986 and 1987 samples, gastropods and bivalves were not distinguished from each other but weighed as one group (e.g. comment code = 87, Table 7). Vegetation present in samples was weighed.

Sediment size, type and organic content

All frozen cores, or one-half cores from 1985, were sent to a registered ASTM contract laboratory for particle size distribution and total organic content (TOC) determinations. Testing was carried out in accordance with ASTM standards D421-85 and D422-63 for sediment particle size preparation and analysis methods, respectively, and standard D2974-87 for organic content determination (ASTM 1989). Standard D2974 was modified for 1986 to 1988 samples because of excess free water in the samples. Samples were not air dried prior to testing, as specified in the standard; but oven dried at 60°C. Then a representative sub-sample, approximately 10 g, was taken from each sample

for determination of organic content. Organic content of the sample was calculated based on dry weight of the sample.

RESULTS

STATION DATA

A summary of stations sampled in Tuktoyaktuk Harbour and Mason Bay is given in Tables 1-4, for 1985 to 1988, respectively. All sampling was conducted in March, with ice depths greatest in 1985 and 1986 when sampling was in the latter part of the month. Interannual variation in 1986 to 1988 within station depths ranged from 0.0 (station T04) to 2.6 m (station T08). In 1985 (Table 1) seven stations were sampled in Tuktoyaktuk Harbour and six in Mason Bay. There was one Van Veen grab sample per station, and two cores (one whole, and one one-half) per station were analysed for benthos. Although three screen sizes were used - 500, 425 and 212 µm - the former two are represented in the data tables of this report as 500 µm as only two were sieved in the 425 µm screen. In each of 1986 to 1988 (Tables 2-4) there were four Van Veen grabs and four cores per station for benthos analysis, with all cores subsequently sieved through three screen sizes - 500, 212 and 64 µm.

Summary data on all Van Veen grab and core sub-samples collected at each station from 1985 to 1988 are shown in Tables 8-11, respectively. For each sample year, a Benthic Sample Number (BSN) was sequentially assigned to each sample type. In 1985 there are five sample types (Van Veen, and two core size fractions for each of the whole and one-half cores) per station; while in 1986 to 1988 there are four sample types (Van Veen, and the three core size fractions) for each of the four grabs at each station. BSNs not listed either represent sub-sample types which were combined and represented in other BSNs (especially in 1985), or are BSNs assigned to facilitate subsequent data analysis (especially for 1986 to 1988 samples); for example, in Table 9 BSN=2 is assigned to the pooled data for the three core size fractions.

SEDIMENT SAMPLE VOLUMES

Grab volumes of all Van Veen samples collected in 1985 to 1988 are given in Tables 8-11, respectively. The grab rejection criteria, of a volume less than 5.0 L (e.g. Gray 1981), occurred for two samples taken during 1985, with an acceptable re-sampling taken for one (station M05). Because this was a preliminary survey, the remaining sample (station M06) was nevertheless processed. The maximum volume of the Van Veen sampler, without resulting in an "overfull" condition, is 26 L. This volume was exceeded for a number of grabs in 1987 (Table 10) and 1988 (Table 11) at a number of stations, particularly T04. Although the grab top is covered with doors and the surface of these grabs did not appear disturbed, epifauna may have been lost during grab retrieval. Sediment volumes of the 1986 to 1988 core sub-samples are also shown.

SUBSTRATE PARTICLE SIZE AND TOTAL ORGANIC CONTENT

Substrate particle size distribution of core sub-samples taken from the 1985 to 1988 Van Veen grabs are reported in Tables 12-15, respectively. Sample distributions are reported as percent of particles finer than the screen aperture (mm), and in phi units [(-log₂)-(particle diameter in mm)]. In all years maximum particle sizes were generally in the 0.125-0.250 mm range. At stations T02 and M07 in 1986 to 1988, maximum particle sizes generally exceeded 0.250 mm.

Textural composition of the sediment, as percent of clay, silt or sand, is shown in Tables 16-19, for 1985 to 1988, respectively. In all years at virtually all stations, sediment texture was 100% clay-silt, with the exceptions of stations T02 and M07 which had a minor sand component. Total organic content data are also shown.

ABUNDANCE AND BIOMASS

A systematic list of specimens identified from all benthic samples collected in 1985 to 1988 is shown in Table 20, with a list of species identified from each year given in Table A2.1 (Appendix A2). An alphabetically ordered specimen list for the 1985 to 1988 collections is given in Table A3.1

(Appendix A3). In 1985 to 1988 a total of 199 taxonomic identifications were made representing 33 taxonomic groups, with four additional miscellaneous groups (880000, and 910000 to 930000) identified. Of the 199 identifications, 165 were at the family, genus or species level, while the balance were at higher systematic levels, including phylum. Identifications from the Polychaeta (18.6%), Copepoda (13.1%), Amphipoda (11.6%), Gastropoda (7.5%), Bryozoa (5.5%) and Bivalvia (4.0%) taxonomic groups contributed about 60% to the total number of 199 identifications.

There are interannual differences in the number of specimen identifications (Table A3.1, Appendix A3). In 1985, there were 87 taxonomic identifications representing 22 taxonomic groups, with four groups, the Polychaeta (23.0%), Amphipoda (11.5%) and Ostracoda (8.1%) and Acari (8.1%) representing about 50% of the total number of identifications. In 1986 to 1988 the total number of taxonomic identifications were respectively, 123, 98 and 110; representing, respectively, for 1986 to 1988, 27, 25 and 27 taxonomic groups. In 1986 the Polychaeta (22.0%), Amphipoda (13.0%), Copepoda (12.2%) and Gastropoda (8.1%) represented 55.3% of the total number of identifications. In 1987 the Copepoda (19.4%), Polychaeta (18.4%), Amphipoda (11.2%) and Bryozoa (6.1%) represented 55.1% of the total number of identifications. In 1988 the Polychaeta (22.7%), Copepoda (14.5%), Amphipoda (13.6%) and Bivalvia (6.3%) represented 57.1% of the total number of identifications.

Count and abundance (number·m⁻²) data for animals collected in the Van Veen samples for 1985 to 1988 is given in Tables 21-24, respectively. Similarly, count and abundance (number·m⁻²) data for animals collected in the core sub-samples at the different sieve sizes, for 1985 to 1988 is shown in Tables 25-28, respectively. As a proportion of the total abundance per sample year, core sub-samples contributed the largest proportion. In 1985, the proportion of the total abundance (18 251 138) in Van Veen, 500 µm whole and half core, and 212 µm whole and half core samples is, 5.8, 3.7, 5.9, 50.8 and 33.8%, respectively. In 1986 the proportion of total abundance (240 377 804) between Van Veen, and 500, 212 and 64 µm core samples is, 2.3, 3.6, 16.1 and 77.9%, respectively. In 1987 the respective

proportion of the total abundance (339 797 042) is, 1.8, 2.6, 15.5 and 80.1%. In 1988 the respective proportion of the total abundance (324 487 553) is, 2.7, 2.8, 18.0 and 76.5%.

Sample abundances (i.e. total abundance, in number·m⁻², of all specimens in a sample type) are given in Tables 8-11 for 1985 to 1988, respectively. In 1985 (Table 8) maximum sample abundance of Van Veen, 500 µm whole and half core, and 212 µm whole and half core sample types is, 179 928 (BSN=78), 260 590 (BSN=81), 705 888 (BSN=104), 1 612 954 (BSN=39) and 1 382 364 (BSN=60), respectively. In 1986 (Table 9) maximum sample abundance of Van Veen, and 500, 212 and 64 µm core sample types is, 278 645 (BSN=231), 582 946 (BSN=238), 2 580 609 (BSN=69) and 14 136 584 (BSN=65), respectively. In 1987 (Table 10) and 1988 (Table 11) respective maximum sample abundances for Van Veen, and 500, 212 and 64 µm sample types are, 308 290 (BSN=176) and 562 745 (BSN=201), 426 474 (BSN=63) and 445 886 (BSN=123), 5 289 454 (BSN=219) and 3 638 853 (BSN=79), and 13 120 105 (BSN=160) and 17 553 082 (BSN=205).

The abundance of all specimens collected at each station, sorted by comment code, for each sample type is shown in Tables 29-32 for 1985 to 1988, respectively. In 1985 (Table 29) there was only one sample of each sample type collected per station, and this table is essentially a reformatted version of Tables 21 and 25. In 1986 to 1988, because there were four samples of each sample type collected per station, the abundances in Tables 30-32 are a "mean" catch-per-unit-effort value, calculated as the sum abundance divided by four (i.e. zero cells were included in the calculation).

The percent contribution by predominant taxonomic groups to each sample type's total abundance in 1985 to 1988 is given in Table 33. The Foraminiferida has the largest percent contribution, irrespective of sample type. The Ostracoda generally contributed the next largest proportion, in 1986 to 1988, but their contribution declined with decreasing sieve size in the core sub-samples. The Nematoda were generally the next most predominant group in the core sub-samples, while polychaetes were more predominant than nematodes in the Van Veen samples. Polychaetes were most abundant in the Van Veen

samples and 500 µm core sub-samples, while copepods and cladocerans were most abundant in the 212 µm core sub-samples.

The percent contribution by predominant taxonomic groups to the number of taxonomic identifications within sample year for each sample type is shown in Table 34. Identifications from the Polychaeta group generally contributed the largest, or next to largest proportion in all sample types. In the Van Veen grabs the Amphipoda had the next largest proportion of identifications, while this was not the case with the 500 µm core sub-samples. As sieve size for the core sub-samples decreased copepod and ostracod identifications became more predominant. The mean number of species identifications by station, year and sample type is shown in Table 35. The mean number of identifications varied considerably between stations within each bay, but there was relatively little inter-annual variation within stations. On a sample type basis, the greatest number of identifications were in the Van Veen samples, while the 500 µm core sub-samples had much fewer identifications. Within the sieve size core series, irrespective of station and year, the number of identifications declined with decreasing sieve size.

Taxonomic group wet weight (g) and biomass (g·m⁻²) data for animals collected in the Van Veen samples for 1986 to 1988 are given in Tables 36-38, respectively. Similarly, wet weight and biomass values for taxonomic groups from the 500 µm core sub-samples collected in 1986 to 1988 are given in Tables 39-41, respectively. All taxonomic groups identified in a sample are tabulated, showing total number in the sample and the number weighed. Included is biomass for plant/vegetative matter. Each taxonomic group's total sample biomass (g·m⁻²) is the group's sample weight standardized to a surface area of 1 m². Comment codes refer to the sample weighed, and are used most frequently to distinguish between different sub-group types for a given taxonomic group [e.g. Table 36, BSN=1, Polychaeta, with weights given for both tube fragments (comment code=12), and live animals and fragments (comment code=85) - compare with specimen data in Table 22], or to identify if, or why, certain groups were not weighed [e.g. Table 36, BSN=221, Ascidiacea, with all specimens stored in the reference collection (comment code=4)]. Note that in most cases bivalves and gastropods were pooled and weighed

as a group (e.g. Table 7, comment codes=87, 88).

Sample wet biomass data (i.e. sum of all taxonomic group wet biomass data in a sample type) are given in Tables 9-11 for 1986 to 1988, respectively. Sample wet biomass for Van Veen samples in 1986 ranged from 13.8 (BSN=6) to 625.7 (BSN=36) g·m⁻², in 1987 from 20.4 (BSN=26) to 485.5 (BSN=1) g·m⁻², and in 1988 from 16.5 (BSN=66) to 613.5 (BSN=1) g·m⁻². Sample wet biomass for the 500 µm core sub-samples in 1986 ranged from 18.8 (BSN=3) to 593.5 (BSN=228) g·m⁻², in 1987 from 9.4 (BSN=203) to 1060.6 (BSN=8) g·m⁻², and in 1988 from 16.5 (BSN=33) to 1220.0 (BSN=3) g·m⁻².

The mean wet biomass of all taxonomic groups collected at a given station, sorted by comment code, for the Van Veen and 500 µm core sub-sample types is shown in Tables 42-44, for 1986 to 1988, respectively. Because there were four samples of each sample type collected per station the biomass values in Tables 42-44 are a "mean" catch-per-unit-effort value, calculated as the sum of wet biomass divided by four (i.e. zero cells were included in the calculation).

The relative percent contribution by taxonomic group and comment code categories to each sample type's total wet biomass, by sample year, is shown in Table 45. Some of the interannual differences result from changes in sampling methods (e.g. Ostracoda, comment code=84, were weighed only in 1988). Plant/vegetative matter and foraminiferans contributed the largest proportion of the wet biomass, irrespective of sample year or sample type. Polychaeta specimens from the various comment code categories were also predominant throughout.

ACKNOWLEDGMENTS

The authors would like to thank the many individuals who assisted in the collection of this data. In particular, we thank G. Lacho, M. Keast, and R. Sauvé of DFO, Winnipeg, and J. Reagan and H. Campbell, foremen for the mobile field camp. Many people at North/South Consultants Inc., Winnipeg, MB, contributed to identification and analysis of samples and we wish to gratefully

acknowledge their collective efforts, time and expertise. We would also like to thank staff of the Polar Continental Shelf Project of the Department of Energy, Mines and resources, Tuktoyaktuk, for logistic support.

Table 7. Key to comment codes that may occur in the 1985 to 1988 data tables.

Code	Comment	Code	Comment
General Comments			
1	unidentified	46	dead - juveniles
2	unidentified - but possibly identifiable to species	47	valves, fragments
3	unidentified - pending verification	48	live - possibly identifiable
4	stored in hypotype reference collection	49	dead - possibly identifiable
5	poor condition	Stomach contents	
6	copepodite - no stage assigned	50	empty stomach
7	exoskeletons/fragments of copepods	51	diet item in stomach
8	>1000 see split	52	diet item in intestine
9	extrapolated	53	digested
10	probably not a representative sample	54	partially digested
Polychaeta			
11	tubes - whole	55	stomach remains
12	tubes - fragments	56	intestine remains
13	body - fragments	57	unidentified detritus
14	body & tube - fragments	58	parasite
15	elytra fragments	59	remains
16	larvae	Copepoda	
Cnidaria			
19	umbrellas only - digested/decomposed	69	nauplius
20	fragments of single organisms	70	adult - no sex (copepodite VI)
21	hydroid	71	copepodite I
22	hydroid colony	72	copepodite II
23	hydromedusae	73	copepodite III
24	medusae	74	copepodite IV
25	anthozoan larvae	75	copepodite V
26	colony fragments	76	adult female (copepodite VI)
Ectoprocta, Entoprocta			
28	colony	77	adult male (copepodite VI)
29	statoblast	78	nauplius <200 µm
30	colony fragment	79	nauplius 200-400 µm
80	nauplius >400 µm	81	copepodite <400 µm - cyclopoids and harpacticoids only
82	copepodite 400-800 µm - cyclopoids and harpacticoids only	83	egg
84	dead animals and fragments	Weights	
85	live animals and fragments	84	dead animals and fragments
86	live and dead animals, and fragments	85	live animals and fragments
87	live gastropods and bivalves	86	live and dead animals, and fragments
88	dead gastropods and bivalves, and/or fragments	87	live gastropods and bivalves
89	did not weigh	88	dead gastropods and bivalves, and/or fragments
90	cypgid	89	did not weigh
91	megalopae	No specific taxon (unless specified)	
92	zoeae	90	cypgid
93	ephippia	91	megalopae
94	egg	92	zoeae
95	egg capsules	93	ephippia
96	egg and egg capsules	94	egg
97	anemone cases	95	egg capsules

Table 8. Summary data for biological samples collected with benthic gear in March, 1985.

Benthic Sample Number	Date	Station		Gear Type ^a	Sediment Volume (L)	Seive Size (μm)	Number of Species Identified	Abundance (No. $\cdot \text{m}^{-2}$)	Wet Biomass (g $\cdot \text{m}^{-2}$)

Order Cephalaspidea		
Family Cylichnidae		
<u>Cylichna</u> sp.	Loven 1846	487570
<u>Cylichna alba</u>	Brown 1827	487571
Family Retusidae		
<u>Retusa obtusa</u> (=pertenuis)	Montagna 1807	487711
Order Mesogastropoda		
Family Trichotropididae		
<u>Trichotropis borealis</u>	Broderip & Sowerby 1829	487742
Order Neogastropoda		
Family Buccinidae		
<u>Buccinum</u> sp.	Linnaeus 1758	487530
Family Cancellariidae		
<u>Admete couthouyi</u>	(Jay 1839)	487501
Family Muricidae		
<u>Boreotrophon clathratus</u>	Linnaeus 1767	487521
Family Neptuneidae		
<u>Volutopsis</u> sp.	Morch 1857	487750
Family Turridae		
<u>Oenopota</u> sp.	Morch 1852	487690
<u>Oenopota</u> cf. <u>cinerrea</u>	(Moller)	487698
<u>Oenopota incisula</u>	(Verrill 1882)	487694
Order Nudibranchia		
Family Eubranchidae		
<u>Eubranchus pallidus</u>	(Alder & Hancock 1842)	487761
Order Thecosomata		
Family Limacinidae		
<u>Limacina helicina</u>	(Phipps 1774)	487631 510000
Class Bivalvia		
Order Myidae		
Family Hiatellidae		
<u>Cyrtodaria kurriana</u>	Dunker 1862	517941
Family Myidae		
<u>Mya arenaria</u>	Linnaeus 1758	518032
Order Mytiloida		
Family Mytilidae		
<u>Mytilus edulis</u>	Linnaeus 1758	518051
Order Nuculoida		
Family Yoldiidae		
<u>Portlandia</u> sp.	Morch 1857	518110
<u>Portlandia arctica</u> var. <u>aestua</u>	(Gray 1824)	518111
Order Veneroida		
Family Tellinidae		
<u>Macoma</u> sp.	Leach 1819	518000
<u>Macoma balthica</u>	(Linnaeus 1758)	518001
Phylum Arthropoda		
Subphylum Chelicerata		
Class Arachnida		
Order Acari		330000
Family Halicaridae

Table A3.1 Alphabetic list of specimens collected in Tuktoyaktuk Harbour and Mason Bay, March, 1985 to 1988.

Specimen Name	Phylum	Taxonomic Group	Species Code
Acanthostepheia behringiensis	Arthropoda	Amphipoda (Order)	436151
Acari (Order)	Arthropoda	Acari (Order)	330000
Acartia bifilosa	Arthropoda	Copepoda (Class)	364103
Aceroides latipes	Arthropoda	Amphipoda (Order)	436161
Aceroides sp.	Arthropoda	Amphipoda (Order)	436160
Admete couthouyi	Mollusca	Gastropoda (Class)	487501
Aetideus pacificus	Arthropoda	Copepoda (Class)	365091
Alcyonidium disciforme	Bryozoa	Bryozoa (Phylum)	558351
Alcyonidium enteromorpha	Bryozoa	Bryozoa (Phylum)	558354
Alcyonidium pedunculatum	Bryozoa	Bryozoa (Phylum)	558355
Alcyonidium sp.	Bryozoa	Bryozoa (Phylum)	558350
Alcyonidium vermiculare	Bryozoa	Bryozoa (Phylum)	558356
Ampharete acutifrons	Annelida	Polychaeta (Class)	232071
Ampharete vega	Annelida	Polychaeta (Class)	232073
Amphipoda (Order)	Arthropoda	Amphipoda (Order)	430000
Amphitrite cirrata	Annelida	Polychaeta (Class)	232091
Amphitrite sp.	Annelida	Polychaeta (Class)	232090
Anonyx nugax	Arthropoda	Amphipoda (Order)	436183
Anthozoa (Class)	Cnidaria	Anthozoa (Class)	100000
Antinoella sp.	Annelida	Polychaeta (Class)	232100
Apherusa glacialis	Arthropoda	Amphipoda (Order)	436191
Asciidiacea (Class)	Chordata	Asciidiacea (Class)	630000
Balanus sp.	Arthropoda	Cirripedia (Class)	385300
Barentsia garbonovi	Entoprocta	Entoprocta (Phylum)	669231
Barentsia sp.	Entoprocta	Entoprocta (Phylum)	669230
Bivalvia (Class)	Mollusca	Bivalvia (Class)	510000
Boecksimus affinis	Arthropoda	Amphipoda (Order)	436241
Boecksimus sp.	Arthropoda	Amphipoda (Order)	436240
Boreotrophon clathratus	Mollusca	Gastropoda (Class)	487521
Bougainvillia sp.	Cnidaria	Hydrozoa (Class)	80880
Bougainvillia yoldiaeearcticae	Cnidaria	Hydrozoa (Class)	80882
Brachiopoda (Phylum)		Brachiopoda (Phylum)	570000
Bryozoa (Phylum)		Bryozoa (Phylum)	550000
Buccinum sp.	Mollusca	Gastropoda (Class)	487530
Bylgides sarsi	Annelida	Polychaeta (Class)	232911
Bythocytherididae (Family)	Arthropoda	Ostracoda (Class)	353970
Calanus glacialis	Arthropoda	Copepoda (Class)	364113
Calanus hyperboreus	Arthropoda	Copepoda (Class)	364114
Calanus sp.	Arthropoda	Copepoda (Class)	364110
Capitella sp.	Annelida	Polychaeta (Class)	232170
Cecidomyiidae (Family)	Arthropoda	Insecta (Class)	467266
Cerebratulus sp.	Nemertea	Nemertea (Phylum)	141500
Cerianthus sp.	Cnidaria	Anthozoa (Class)	101130
Chironomidae (Family)	Arthropoda	Insecta (Class)	467250
Cirratulidae (Family)	Annelida	Polychaeta (Class)	232210
Cladocera (Suborder)	Arthropoda	Cladocera (Suborder)	370000
Copepoda (Class)	Arthropoda	Copepoda (Class)	360000
Cossura longocirrata	Annelida	Polychaeta (Class)	232222
Cossura sp.	Annelida	Polychaeta (Class)	232220
Crinoidea (Class)	Echinodermata	Crinoidea (Class)	590000
Crisia sp.	Bryozoa	Bryozoa (Phylum)	558420
Cristatella mucedo	Bryozoa	Bryozoa (Phylum)	558381
Cumacea (Order)	Arthropoda	Cumacea (Order)	390000
Cyclopoida (Order)	Arthropoda	Copepoda (Class)	365020
Cyclops bicolor	Arthropoda	Copepoda (Class)	364133
Cyclops bicuspidatus	Arthropoda	Copepoda (Class)	364132
Cyclops sp.	Arthropoda	Copepoda (Class)	364130
Cyclops vernalis	Arthropoda	Copepoda (Class)	364131
Cyclops vp. vernalis	Arthropoda	Copepoda (Class)	364134
Cyllichna alba	Mollusca	Gastropoda (Class)	487571
Cyllichna sp.	Mollusca	Gastropoda (Class)	487570
Cyrtodaria kurriana	Mollusca	Bivalvia (Class)	517941
Cytheridae (Family)	Arthropoda	Ostracoda (Class)	353860

Table A3.1 Alphabetic list of specimens collected in Tuktoyaktuk Harbour and Mason Bay, March, 1985 to 1988 (CONTINUED).

Specimen Name	Phylum	Taxonomic Group	Species Code
Cytherideidae (Family)	Arthropoda	Ostracoda (Class)	353880
Daphnia sp.	Arthropoda	Cladocera (Suborder)	375110
Decapoda (Order)	Arthropoda	Decapoda (Order)	450000
Diaptomus oregonensis	Arthropoda	Copepoda (Class)	364175
Diastylis rathkei	Arthropoda	Cumacea (Order)	395375
Diastylis sp.	Arthropoda	Cumacea (Order)	395370
Drepanopus bungei	Arthropoda	Copepoda (Class)	364181
Dyopodus porrectus	Arthropoda	Amphipoda (Order)	436301
Echinoidea (Class)	Echinodermata	Echinoidea (Class)	620000
Echiura (Phylum)		Echiura (Phylum)	210000
Edwardsiidae (Family)	Cnidaria	Anthozoa (Class)	101120
Entoprocta (Phylum)		Entoprocta (Phylum)	660000
Eubranchus pallidus	Mollusca	Gastropoda (Class)	487761
Euchone analis	Annelida	Polychaeta (Class)	232281
Euchone papillosa	Annelida	Polychaeta (Class)	232282
Euchone sp.	Annelida	Polychaeta (Class)	232280
Eucratea loricata	Bryozoa	Bryozoa (Phylum)	558391
Eucratea sp.	Bryozoa	Bryozoa (Phylum)	558390
Flustra sp.	Bryozoa	Bryozoa (Phylum)	558400
Foraminiferida (Order)	Sarcomastigophora	Foraminiferida (Order)	60000
Gaidius tenuispinus	Arthropoda	Copepoda (Class)	364241
Gammarus wilkitzkii	Arthropoda	Amphipoda (Order)	436353
Gastropoda (Class)	Mollusca	Gastropoda (Class)	480000
Gattyana sp.	Annelida	Polychaeta (Class)	232320
Halacarus basteri basteri	Arthropoda	Acari (Order)	333401
Halecium sp.	Cnidaria	Hydrozoa (Class)	80780
Halicyprytus sp.	Priapulida	Priapulida (Phylum)	191800
Halicyprytus spinulosus	Priapulida	Priapulida (Phylum)	191801
Harpacticoida (Order)	Arthropoda	Copepoda (Class)	365030
Harpacticus sp.	Arthropoda	Copepoda (Class)	364250
Hartmeyeria sp.	Chordata	Asciidiacea (Class)	639140
Hemicythere sp.	Arthropoda	Ostracoda (Class)	353891
Heterocyprideidae (Family)	Arthropoda	Ostracoda (Class)	353881
Heteronemertea sp.	Nemertea	Nemertea (Phylum)	141530
Hoploneuritea sp.	Nemertea	Nemertea (Phylum)	141520
Hyas sp.	Arthropoda	Decapoda (Order)	457110
Hydrozetes sp.	Arthropoda	Acari (Order)	333410
Hydrozoa (Class)	Cnidaria	Hydrozoa (Class)	80000
Hyperiidae sp.	Arthropoda	Amphipoda (Order)	436730
Insecta (Class)	Arthropoda	Insecta (Class)	460000
Jaschnovia (=Derjuginia) tolli	Arthropoda	Copepoda (Class)	364471
Kinorhyncha (Phylum)		Kinorhyncha (Phylum)	170000
Lanassa sp.	Annelida	Polychaeta (Class)	232370
Lanassa sp. nr L. venusta	Annelida	Polychaeta (Class)	232372
Laophonte sp.	Arthropoda	Copepoda (Class)	365050
Leptostylis longimana	Arthropoda	Cumacea (Order)	395411
Leptostylis sp.	Arthropoda	Cumacea (Order)	395410
Limacina helicina	Mollusca	Gastropoda (Class)	487631
Limnocalanus macrurus	Arthropoda	Copepoda (Class)	364281
Limnocalanus sp.	Arthropoda	Copepoda (Class)	364280
Liamocytheridae (Family)	Arthropoda	Ostracoda (Class)	353900
Lysippe labiata	Annelida	Polychaeta (Class)	232431
Macoma balthica	Mollusca	Bivalvia (Class)	518001
Macoma sp.	Mollusca	Bivalvia (Class)	518000
Margarites olivaceus	Mollusca	Gastropoda (Class)	487652
Mesidotea entomon	Arthropoda	Isopoda (Order)	425811
Mesidotea sp.	Arthropoda	Isopoda (Order)	425810
Mesocyclops edax	Arthropoda	Copepoda (Class)	365081
Metopa sp.	Arthropoda	Amphipoda (Order)	436450
Metridia longa	Arthropoda	Copepoda (Class)	364301
Microcalanus pygmaeus	Arthropoda	Copepoda (Class)	364311
Micronephthys minuta	Annelida	Polychaeta (Class)	232481
Micronephthys sp.	Annelida	Polychaeta (Class)	232480

Table A3.1 Alphabetic list of specimens collected in Tuktoyaktuk Harbour and Mason Bay, March, 1985 to 1988 (CONTINUED).

Specimen Name	Phylum	Taxonomic Group	Species Code
Monoculodes packardi	Arthropoda	Amphipoda (Order)	436473
Monoculodes sp.	Arthropoda	Amphipoda (Order)	436470
Mya arenaria	Mollusca	Bivalvia (Class)	518032
Mytilus edulis	Mollusca	Bivalvia (Class)	518051
Nematoda (Phylum)		Nematoda (Phylum)	180000
Nemertea (Phylum)		Nemertea (Phylum)	140000
Nephytis ciliata	Annelida	Polychaeta (Class)	232501
Nephytis neotena	Annelida	Polychaeta (Class)	232482
Nereimyra aphroditoides	Annelida	Polychaeta (Class)	232511
Nereimyra sp.	Annelida	Polychaeta (Class)	232510
Obelia sp.	Cnidaria	Hydrozoa (Class)	80820
Oenopota cf. cinerea	Mollusca	Gastropoda (Class)	487698
Oenopota incisula	Mollusca	Gastropoda (Class)	487694
Oenopota sp.	Mollusca	Gastropoda (Class)	487690
Oikopleura sp.	Chordata	Larvacea (Class)	649200
Oikopleura vanhoeffeni	Chordata	Larvacea (Class)	649201
Oligochaeta (Class)	Annelida	Oligochaeta (Class)	310000
Oncae borealis	Arthropoda	Copepoda (Class)	364361
Onisimus glacialis	Arthropoda	Amphipoda (Order)	436501
Onisimus littoralis	Arthropoda	Amphipoda (Order)	436502
Onisimus nanseni	Arthropoda	Amphipoda (Order)	436503
Onisimus sp.	Arthropoda	Amphipoda (Order)	436500
Orthonotacythere (Family)	Arthropoda	Ostracoda (Class)	353940
Ostracoda (Class)	Arthropoda	Ostracoda (Class)	350000
Paracyprideis sp.	Arthropoda	Ostracoda (Class)	353931
Parathemisto sp.	Arthropoda	Amphipoda (Order)	436530
Paroedicerus lynceus	Arthropoda	Amphipoda (Order)	436551
Pectinaria hyperborea	Annelida	Polychaeta (Class)	232571
Pectinaria sp.	Annelida	Polychaeta (Class)	232570
Pholoe cf. longa	Annelida	Polychaeta (Class)	232593
Pholoe longa	Annelida	Polychaeta (Class)	232592
Phyllodoce groenlandica	Annelida	Polychaeta (Class)	232601
Piona exilis	Arthropoda	Acari (Order)	333441
Plant/Vegetative matter			930000
Podocopa (Order)	Arthropoda	Ostracoda (Class)	353850
Polychaeta (Class)	Annelida	Polychaeta (Class)	230000
Polydora quadrilobata	Annelida	Polychaeta (Class)	232624
Pontoporeia affinis	Arthropoda	Amphipoda (Order)	436591
Pontoporeia femorata	Arthropoda	Amphipoda (Order)	436592
Pontoporeia sp.	Arthropoda	Amphipoda (Order)	436590
Portlandia arctica var. aestua	Mollusca	Bivalvia (Class)	518111
Portlandia sp.	Mollusca	Bivalvia (Class)	518110
Priapulida (Phylum)	Priapulida	Priapulida (Phylum)	190000
Priapulus bicaudatus	Priapulida	Priapulida (Phylum)	191811
Priapulus caudatus	Priapulida	Priapulida (Phylum)	191812
Priapulus sp.	Priapulida	Priapulida (Phylum)	191810
Prionospio cirrifera	Annelida	Polychaeta (Class)	232661
Pseudocalanus minutus	Arthropoda	Copepoda (Class)	364392
Pycnophyes canadensis	Kinorhyncha	Kinorhyncha (Phylum)	171701
Pycnophyes sp.	Kinorhyncha	Kinorhyncha (Phylum)	171700
Quinqueloculina sp.	Sarcomastigophora	Foraminiferida (Order)	60410
Retusa obtusa (=pertenuis)	Mollusca	Gastropoda (Class)	487711
Rotalina (Suborder)	Sarcomastigophora	Foraminiferida (Order)	60450
Sagitta elegans	Chaetognatha	Chaetognatha (Phylum)	588661
Schistomerings caeca	Annelida	Polychaeta (Class)	232711
Schistomerings sp.	Annelida	Polychaeta (Class)	232710
Scolecolepides arctius	Annelida	Polychaeta (Class)	232721
Semibalanus balanoides	Arthropoda	Cirripedia (Class)	385301
Sertularia sp.	Cnidaria	Hydrozoa (Class)	80850
Stelleroidea (Class)	Echinodermata	Stelleroidea (Class)	600000
Tardigrada (Phylum)		Tardigrada (Phylum)	470000
Terebellides stroemi	Annelida	Polychaeta (Class)	232781
Textulariina (Suborder)	Sarcomastigophora	Foraminiferida (Order)	60460

Table A3.1 Alphabetic list of specimens collected in Tuktoyaktuk Harbour and Mason Bay, March, 1985 to 1988 (CONTINUED).

Specimen Name	Phylum	Taxonomic Group	Species Code
Tharyx sp.	Annelida	Polychaeta (Class)	232790
Tintinnida (Order)	Ciliophora	Ciliophora (Phylum)	40100
Tiphys sp.	Arthropoda	Acari (Order)	333450
Trachyleberididae (Family)	Arthropoda	Ostracoda (Class)	353920
Trichotropis borealis	Mollusca	Gastropoda (Class)	487742
Trochochaeta carica	Annelida	Polychaeta (Class)	232801
Tubificoides cuspisetosus	Annelida	Oligochaeta (Class)	313271
Tubificoides sp.	Annelida	Oligochaeta (Class)	313270
Unidentified egg			920000
Unidentified fish egg			880000
Unidentified invertebrate			910000
Unionicola crassipes laurentia	Arthropoda	Acari (Order)	333461
Unionicola sp.	Arthropoda	Acari (Order)	333460
Volutopsius sp.	Mollusca	Gastropoda (Class)	487750
