Information to access the product

This product, catalogue no. 81-595-MIE, is available for free in electronic format. To obtain a single issue, visit our website at www.statcan.ca and select Publications.

Standards of service to the public

Statistics Canada is committed to serving its clients in a prompt, reliable and courteous manner. To this end, the Agency has developed standards of service which its employees observe in serving its clients. To obtain a copy of these service standards, please contact Statistics Canada toll free at 1-800-263-1136. The service standards are also published on www.statcan.ca under About us > Providing services to Canadians.

Acknowledgements

The assistance of numerous individuals was critical to the production of this report and we gratefully acknowledge their contributions. A special thank you is extended to Health Canada and to all those individuals who helped to prepare the data and those who provided valuable feedback throughout the preparation and the review of the report.

Note of appreciation

Canada owes the success of its statistical system to a long-standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.

Acronyms

The following acronyms are used in this publication:

ACHDHR	Advisory Committee on Health Delivery and Human Resources
AETS	Adult Education and Training Survey
CEGEP	Collège d'enseignement général et professionnel
CIP	Classification of Instructional Programs
CV	Coefficient of variation
PSIS	Postsecondary Student Information System
HHRE	Health Human Resources and Education
LPN	Licensed Practical Nurse
LSIC	Longitudinal Survey of Immigrants to Canada
M.D.	Medical Doctor
NAFTA	North American Free Trade Agreement
NAHO	National Aboriginal Health Organization
NAICS	North American Industrial Classification System
NGS	National Graduates Survey
NOC-S	National Occupational Classification – Statistics
OECD	Organisation for Economic Co-operation and Development
Ph.D.	Doctorate of philosophy
PISA	Programme for International Student Assessment
PLAR	Prior Learning Assessment and Recognition
RN	Registered Nurse
SOC	Standard Occupational Classification
UCASS	University and College Academic Staff Survey
USIS	University Student Information System
WES	Workplace and Employee Survey
YITS	Youth in Transition Survey

Executive summary

There has been much talk recently about looming shortages in Canada's supply of individuals working in health occupations. To understand the degree to which the supply of workers in health occupations is meeting (and will meet) the health needs of Canadians, Health Canada—through the Advisory Committee on Health Delivery and Human Resources (ACHDHR)—contracted the Centre for Education Statistics at Statistics Canada to study the relationship between education and training and the supply of entrants into health occupations.

Using major Statistics Canada data sources related to the education and training of Canadians, the intent of this report is to present available information that can address some of the questions identified during the Health Human Resources and Education (HHRE) nation-wide consultation held in 2005 (see Allen et. al. 2006). As such, this report reveals some important information about what happens before, during and after health education. It focuses on interest in health occupations, the characteristics of students and faculty in postsecondary health programs, the labour market experiences of recent graduates from these programs, as well as the ongoing participation of health workers in formal and informal training.

As a starting point in understanding the flow of individuals into and through health education programs, it is important to learn more about the size and nature of the population of individuals who are interested in health occupations.

There is a great deal of interest in health occupations among youth as they enter high school. Over 10% of 15-year-olds say they want to work in a health occupation and most of them have been interested in that job for at least a year. By the time they complete high school, however, many youth change their minds and only half of those who wanted to work in health still do. But this is still a substantial number of youth and many of them appear highly qualified.

Immigration is an increasingly important component of net population growth in Canada and a large proportion of immigrants make a contribution to the pool of people with postsecondary qualifications. Prior learning assessment and recognition (PLAR) is a particularly important mechanism for the recognition of the international credentials of immigrants who want to work in health occupations. Of the 4% of immigrants who said they wanted to work in health-related occupations before immigrating to Canada, only about a third asked to have their credentials checked during their first two years in Canada, but over 70% of them obtained a full or partial recognition of their credentials.

Several reasons prevented some of the immigrants from going through the PLAR process, but the most often stated reasons were that they did not know where to go or how to get their credentials checked or they believed they would not be accepted.

Educators have an impact on both the capacity and the quality of health-related education programs. Of the 37,000 full-time university teachers in Canada, about 21% teach a health-related subject, and men make up 62% of these. Most of the university full-time academic staff have a doctorate or a professional degree and, depending on their work arrangement (or on their type of appointment), some may be engaged in the practice of a health-related occupation as well as in the teaching of a health-related subject at the university. Similar to what is observed for university faculty overall, full-time university faculty in health are ageing and one in three continue to work after age 55, the average age varying between 47 and 51 in all health-related subjects.

Enrolment information provides an indication of the magnitude of activity taking place in the different health education programs and the relative size of these programs within the university system. In 2004/05, health students accounted for between 6% and 8% of enrolment in universities, with nursing among the largest programs at each level of study.

Most students in health programs are enrolled full-time and the majority are women, similar to what is observed in the health occupations. Given the multiple pathways into and through health studies, students in health programs are more likely to have some previous postsecondary experience and/or full-time work experience. As a result, students enrolled in and graduating from health programs tend to be older than average.

Monitoring the characteristics of graduates from health programs is important because their makeup can change the existing labour force profile of health occupations and have implications for the delivery of services and impact on the human resource management.

In 2000, health graduates represented 7% of bachelor graduates and 14% of college graduates. They are generally more likely to be women, are more likely to have some previous postsecondary education and/or full-time work experience, tend to be older than graduates overall, and are more likely to be married.

As there is a clear demand for their skills, graduates from health programs tend to make quick transitions into the labour market. Within two years of graduating, over three-quarters of health graduates are employed in a health occupation, and some others work in related fields. Almost all health graduates (99%) who have not gone on to additional studies are employed two years after graduation, most of them in a full-time position. Moreover, even just two years after graduation, when some, particularly doctors, are still in residency or entry-level positions, they tend to earn more than graduates overall.

Higher likelihood of employment combined with higher earnings compensates for the fact that health graduates are more likely to have student debt and they tend to owe more. In spite of this, they are less likely to report difficulties repaying their loans, they are just as likely to have paid off their loans two years after graduation, and just as likely to expect to have their loans repaid within five years of graduating.

The ability and willingness of adults to continue learning throughout their lives has been identified as a critical element in Canada's economic future. The need for new skills in the economy has had a profound impact on jobs, in most, if

not all, industries and occupations. With advances in health care knowledge and technology, it is particularly important that adults working in a health occupation be able to maintain and upgrade their skills and knowledge through continuing education.

Traditionally, many of these new skills would have been provided by “new” workers, both young adults and immigrants entering the labour force. However, the demographic reality is that smaller cohorts of young workers will be entering the workforce and, as the work force ages, the potential for skill shortages grows. The “upskilling” of workers already in the labour force is widely seen as an important measure to meet these needs (Peters 2004).

Recognizing this need for ongoing learning, employers often encourage and support continuing education. This is particularly true in health occupations where regulatory frameworks often require ongoing maintenance or upgrading of skills.

During 2003, six in ten workplaces in the health care and social assistance sector supported training activities for their employees. Not surprisingly, larger workplaces or workplaces which introduced innovations during the year were more likely than others to support training activities.

After entering the labour market, health workers continue to upgrade their skills, even when not required. Support for formal training is high among health employers and their workers take advantage of it. About 60% of adults in health occupations participated in formal job-related training in 2002, twice the rate observed for all occupations. The main reason for taking this training is to perform their job better. And while most courses are supported by employers, few of the courses taken are actually required by them. At the same time, however, about one-third of adults in health occupations reported unmet training needs, saying that there was training that they wanted or needed, but were unable to take.

1. Introduction

There has been much talk recently about looming shortages in Canada's supply of individuals working in health occupations. In Canada and internationally, a great deal of work is being done to monitor and to understand the degree to which the supply of workers in health occupations is meeting (and will meet) the health needs of the population. A common theme throughout this work is the need for new and improved information for monitoring health human resources to assist in planning for future requirements.

In 2004, as part of the work coordinated through the Advisory Committee on Health Delivery and Human Resources (ACHDHR), Health Canada contracted the Centre for Education Statistics at Statistics Canada to study the relationship between education and training and the supply of entrants into health occupations. The work of this project is designed to fit within a broader framework for health human resources management outlined by O'Brien-Pallas, Tomblin Murphy (see Appendix 1 in Allen et. al. 2006) as well as the Canadian Institute for Health Information's work on minimum data sets for health human resources management (Tomblin Murphy, O'Brien-Pallas and the Canadian Institute for Health Information 2005).

Concepts and definitions

Occupation is a standard term used by Statistics Canada and can be used to describe all forms of work. For the purpose of this report, the term “occupation” is preferred to “profession” as it does not imply the application of “professional” standards by a professional organization or other authority.

Health and health-related occupations cover a wide range of occupations related to health services and delivery (excluding veterinarians and veterinary and animal health technologists and technicians). Occupations are classified according to standard classifications (1991 Standard Occupational Classification (SOC 1991) or 2001 National Occupational Classification – Statistics (NOC-S 2001)) depending on the data source. As such, health and health-related occupations include, but are not limited to, practitioners of health care. Please refer to Appendix 2 for a complete list of health and health-related occupations as per the SOC 1991 and NOC-S 2001 standard classifications.

Health workers are persons in the health and health-related occupations. Using 2001 Census data, Galarneau (2003) indicated that about 808,000 persons worked in the health field, accounting for about 5% of the labour force during that year. Health professionals accounted for 57% of all workers in health occupations, the majority being nurses (64%), with physicians—general practitioners and specialists—far behind at 14%.

Women account for a large proportion of health workers. In 2001, nearly four health workers in five were women (79%) compared with slightly less than half in other sectors. The average age of health workers was also generally higher than in other sectors (41.1 compared with 38.3).

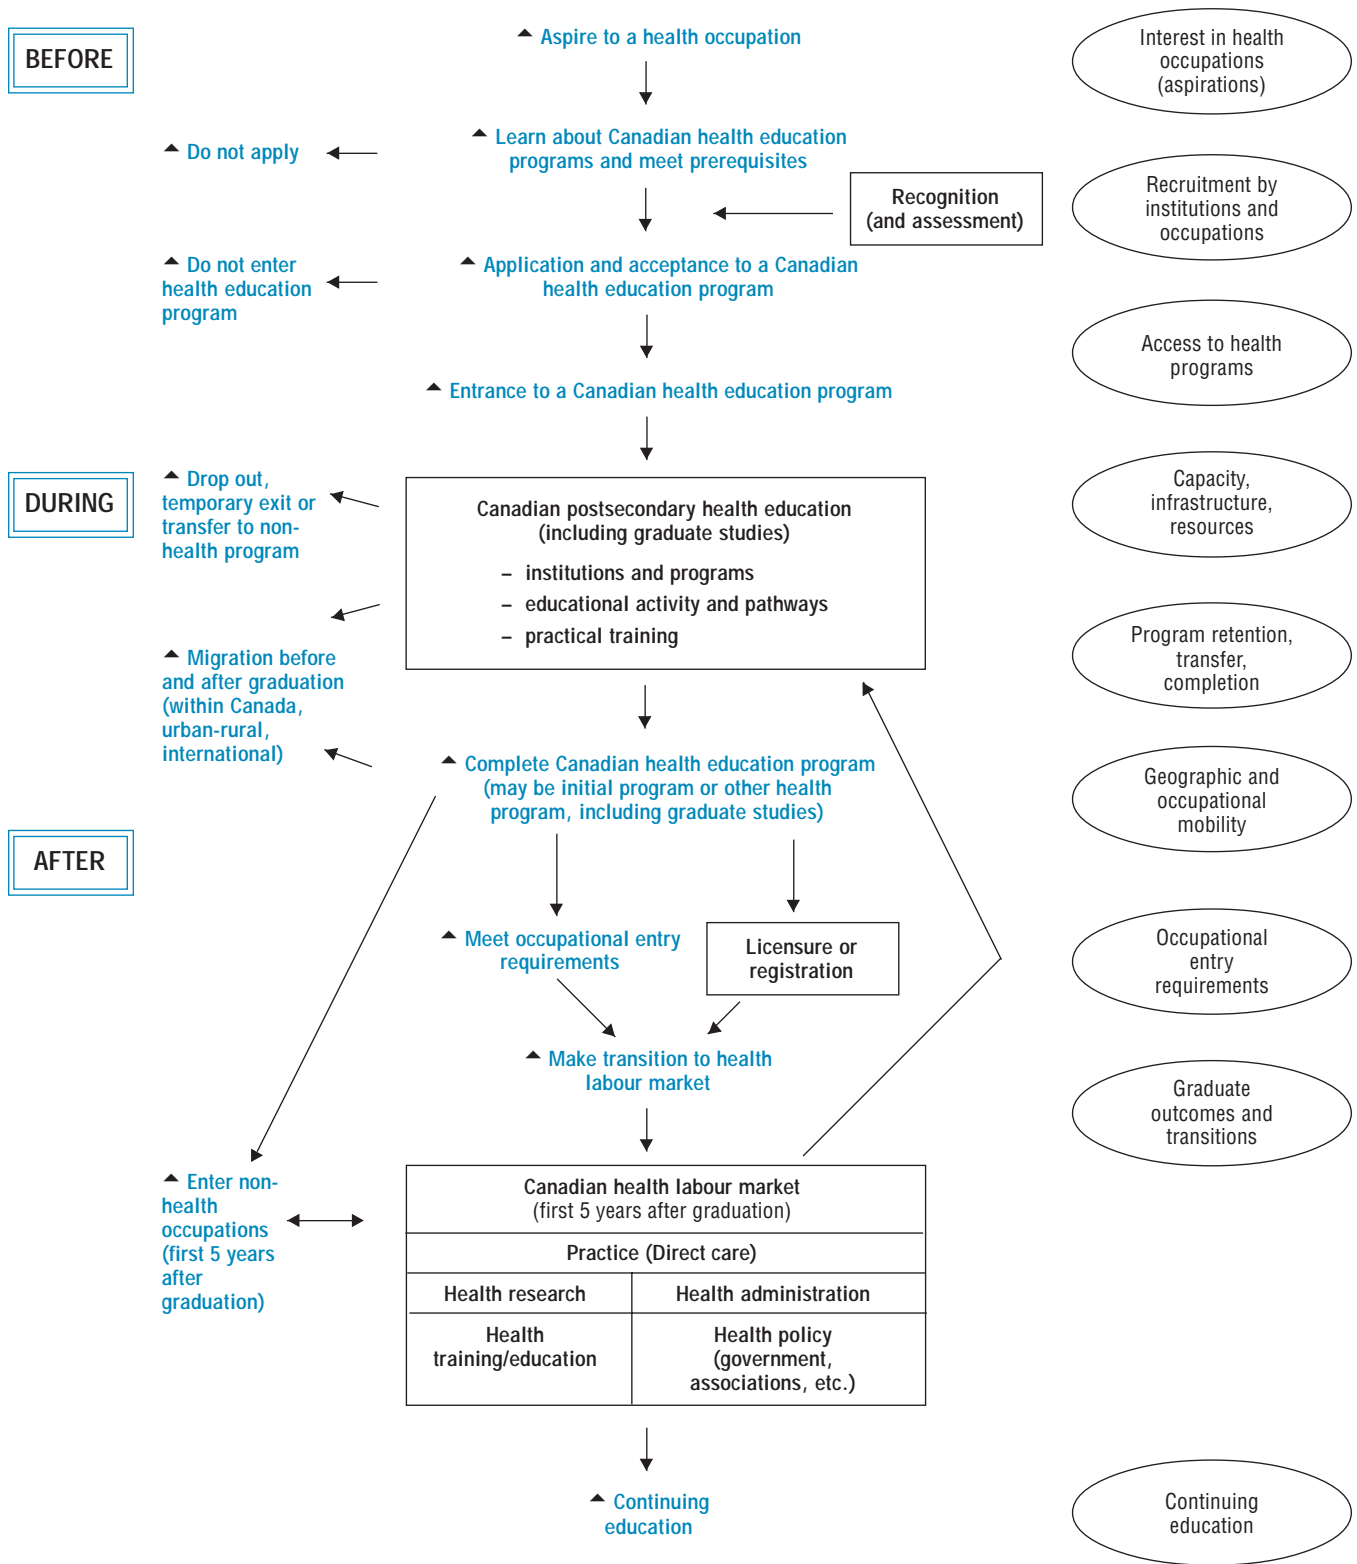

Although a majority of health workers (57%) were employed full-time in 2001, health workers were more likely than those in other sectors to work part-time (28% compared with 21%). The greater prevalence of part-time may be related to the difficulty nurses experience in obtaining full-time positions as well as to the large proportion of women in health occupations. The unemployment rate for health workers in 2001, on the other hand, was considerably lower than for other workers (1.9% compared with 5.6%).

The median employment income of health workers was about \$32,400 in 2001. Among health workers, professionals showed the highest median income with \$42,000, followed by technical personnel (\$32,000) and support personnel (\$21,000).

Health and health-related education programs cover a wide range of programs in fields of study leading to occupations related to health services and delivery. These include, but are not limited to, future practitioners of health care. Fields of study data are coded and presented by Statistics Canada according to the Classification of Instructional Programs (CIP), Canada, 2000. Please refer to Appendix 3 for a complete list of health and health-related programs included in the CIP 2000 standard classification.

The first stage of the Health Human Resources and Education (HHRE) project, which focuses solely on the role of the education system in overall health human resources management, was to identify the information needs related to HHRE. This was done through consultations with a variety of stakeholders during 2005. During this stage, an HHRE conceptual framework (see Figure 1.1) was developed to illustrate the generic flows of individuals through educational institutions and into the health labour market (refer to Appendix 8 for more information on the HHRE conceptual framework). The information needs collected during the consultations have been incorporated into this framework and published in “Health Human Resources and Education: Outlining Information Needs” (Allen et. al. 2006).

Figure 1.1
Health human resources and education (HHRE) conceptual framework

This first data report marks the second stage of the HHRE project. Using already existing datasets, the intent of this report is to present detailed information that can address some of the questions identified during the HHRE consultation process (see Allen et. al. 2006). It does not address all of the questions identified during this consultation, only those for which data are currently available. As such, the report is primarily comprised of information tables accompanied by some brief analysis intended to highlight broad findings that may guide the reader in interpreting the tables.

The analysis presented in this first data report follows the “flow” structure of the HHRE conceptual framework, structuring information needs into “before,” “during” and “after” health education.

The first sections of the analysis present information related to what happens before entry into health education programs, which encompass questions related to interest in health occupations. Questions on recognition of foreign credentials by educational institutions are also addressed in this section.

This is followed by information on the period “during” health education, which covers questions about educators teaching in health education programs and characteristics of students enrolled in such programs.

The final sections of the report encompass information about the period immediately following graduation. They include basic information on the characteristics of graduates from health education programs and detailed information on their transitions into the labour market, including work activity, earnings and pursuit of additional education. The second part of this section encompasses information on the supply of continuing education in workplaces and participation of adults in such training.

Note to readers

Data tables

Tables appearing at the end of each section encompass data information needs identified during the consultation process (see Allen et. al. 2006). These tables have been generated using different data sources described in Appendix 1 and, as a general rule, show aggregates at the Canada level.

For more information about the different survey methodologies, including weighting and non-response adjustments, readers should visit www.statcan.ca. Click on **English** button, click **Definitions, data sources and methods** link in the left navigation panel, click on **Alphabetical lists** under the Surveys and statistical programs category and then, click on the appropriate survey.

Data quality indicators

Data collected from sample surveys are presented in the tables along with data quality indicators (standard errors), which will help in the interpretation of the different survey results.

Standard errors are used to express the degree of uncertainty associated with sampling error and measurement error. The standard error can be used to construct a confidence interval, which provides a mean of making inferences about the population means and proportions in a manner that reflects the uncertainty associated with sample estimates. A 95% confidence interval is used in this report and represents a range of plus or minus about two standard errors around the sample average. Using this confidence interval it can be inferred that the population mean or proportion would lie within the confidence interval in 95 out of 100 replications of the measurement, using different samples randomly drawn from the same population.

Thresholds related to the reliability of the estimate (denoted by "E" or "F") are a function of the standard error as measured by the Coefficient of Variation or CV. Estimates are suppressed (shown by F) where the CV is above 33.3% of the estimate. Where the CV is from 16.6% to 33.3%, data reliability is noted with an "E".

Otherwise stated, comparisons of estimates in the text are considered to be reliable if differences are statistically significant with a 95% level of confidence.

2. Interest in health occupations

As a starting point in understanding the flow of individuals into and through health education programs, it is important to learn more about the size and nature of the population of individuals who are interested in health occupations, when these interests develop (or disappear) and how they learn about possible occupations.

2.1 Data sources and methodological notes

The data for this section comes from the **Youth in Transition Survey (YITS)**. The Youth in Transition Survey is a longitudinal survey of two cohorts of youth (aged 15 and 18 to 20 in 2000) first interviewed in 2000 and followed up every two years. The 15-year-old cohort also participated in the **Programme for International Student Assessment (PISA)** which assessed reading, mathematics, and science skills. Data on the 15-year-olds also included information collected from parents. Most of the data in this section were collected in reference year 2000.

The survey population for the 15-year-olds comprises students who were born in 1984 and were attending any form of schooling in the ten provinces of Canada in 2000. Schools on Indian reserves were excluded, as were various types of schools for which it would be infeasible to administer the survey, such as home schooling and special needs schools. These exclusions represent less than 4% of 15-year-olds in Canada. The sample design for this cohort entails two-stage probability sampling, with a stratified sample of 1,200 schools selected at the first stage and a sample of eligible students selected within each sampled school. The initial student sample size for the reading cohort which was conducted in 2000 was 38,000.

The survey population for the 18- to 20-year-old cohort, on the other hand, includes persons born in the years 1979 to 1981. Geographically, the target population excludes the northern territories, Indian reserves, Canadian Forces bases and some remote areas. Factors such as the high mobility rate of the 18-20 year-old cohort and its relatively low incidence at the household level led to a stratified multi-stage sample design based on the use of the Labour Force Survey sample, drawing from currently active and rotate-out households. Within each household, one person in the target population was pre-selected for YITS. The initial sample size was 29,000 persons.

Among the 15-year-olds and the 18- to 20-year-old cohort, only those who responded in Cycle 2 were re-contacted in Cycle 3. The resulting sample size was 26,854 for the 15-year-olds and 18,743 for the 18- to 20-year-old cohort.

Please refer to Appendix 1 for more information on these two surveys.

In YITS, **occupations** are those reported in the question “What kind of career or work would you be interested in having when you are about 30 years old?” Responses were then coded according to the 1991 Standard Occupational Classification (SOC 1991). These occupations will therefore reflect knowledge of occupations and may not be accurate at a detailed level. For example, the number of youth interested in being registered nursing assistants or licensed practical nurses (LPN) is small, possibly because a generic response of “nurse” would be coded to registered nurse (RN) because of a lack of details.

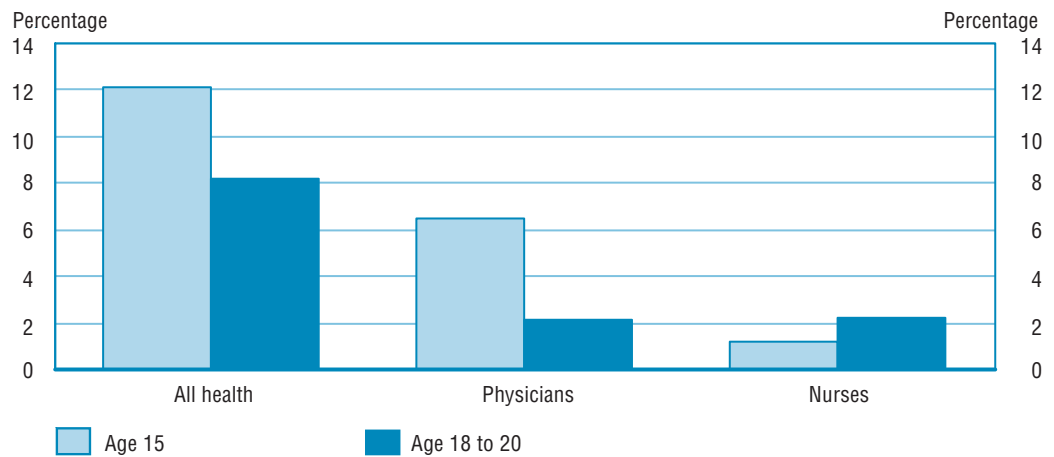

2.2 Aspiring to health occupations

Over 10% of 15-year-olds aspire to work in health occupations, and most say they want to be doctors

At age 15, when asked what job they would like at age 30, 12% of youth named a health occupation and another 3% cited the health-related occupations of psychologist and social worker. There is a notable preference for medicine, with almost 7% wanting to be a doctor. By the time youth are out of secondary school (at age 18 to 20), the proportion has fallen, but still, 8% aspire to health occupations, about 2% to medicine (Chart 2.1, Tables 2.1 and 2.2).

Chart 2.1

A substantial proportion of youth aspire to health occupations

Note: “Nurses” refer to the Nurse supervisors and registered nurses category as reported in Tables 2.1 and 2.2 (e.g., nurse supervisors, registered nurses, registered psychiatric nurses, etc.).

Source: 2000 Youth in Transition Survey, Statistics Canada.

The number of youth interested in health occupations is considerable when you take into account that only 5% of the labour force works in a health occupation and another 1% are in health-related occupations. Most notably, less than 1% of the labour force are physicians. Nursing comprises a much larger occupation, slightly less than 2% of the labour force, and is the desired job for about 1% of 15-year-olds and 2% of 18- to 20-year-olds (Chart 2.1, Tables 2.1 and 2.2) (Statistics Canada 2001b).

Youth who aspire to health occupations tend to be female, they are more likely to be members of a visible minority, and tend to come from more advantaged families

About three-quarters of the youth who aspire to health occupations are female (Tables 2.3 and 2.4). This mirrors the labour force where 79% of workers in health occupations are women (Statistics Canada 2001b).

The youth who are interested in health occupations are more likely to be visible minorities than youth overall. A significant proportion of the youth who want to work in health occupations are members of a visible minority (20% compared to 13% of all youth). Among the youth who want to be doctors, the difference is substantial. Over one-quarter of the 15-year-olds and about one-third of the 18- to 20-year-olds who aspire to medicine are members of a visible minority (Tables 2.3 and 2.4).

This is also reflected in the language of the 15-year-olds who aspire to health occupations. Almost one in five (18%) report a mother tongue other than English or French (compared to 12% of all youth). Among those interested in health occupations overall, the proportion reporting French as mother tongue is typical of youth overall. However, this ranges by occupation and differs by age (Tables 2.7 and 2.8).

The concept of **visible minority** applies to persons who are identified according to the *Employment Equity Act* as being non-Caucasian in race or non-white in colour. Under the Act, Aboriginal persons are not considered to be members of visible minority groups.

Mother tongue refers to the first language learned at home in childhood and still understood by the individual.

Youth who aspire to health occupations tend to come from more advantaged family backgrounds. They are more likely to have at least one parent with a postsecondary education (Tables 2.5 and 2.6) and they are more likely to come from families with higher income (Table 2.9).

This is particularly true for those who aspire to medicine. Three-quarters of youth who say they want to be a physician have postsecondary-educated parents (compared to 62% of all youth), and 32% come from families in the top income quartile. By contrast, youth who aspire to be nurses are less likely than average to have postsecondary-educated parents, and about 14% come from families in the top income quartile (36% in fact come from the bottom income quartile). This difference between aspiring doctors and nurses is also reflected in the rural-urban mix. Youth aspiring to be doctors are more likely than average to come from urban centres, while those who aspire to be nurses are more likely than average to come from rural areas (Tables 2.5, 2.6 and 2.9).

Youth aspiring to health occupations have higher than average skill levels and are more likely to have gone on to university by age 18 to 20

Youth aiming for health occupations tend to have higher than average skills. The 15-year-olds interested in health occupations scored higher on the PISA international assessment in reading, mathematics and science. These scores ranged widely, however, depending on the occupation. While youth aspiring to medicine had notably high scores, those aspiring to nursing and technical occupations in

health had scores below the average obtained by youth interested in health occupations overall. More than half of those aspiring to medicine (66%) scored above average in reading (level 4 or 5) compared to only 38% of youth who wanted to be nurses (Tables 2.10 and 2.11).

Reading literacy is defined in the Programme for International Student Assessment (PISA) as the ability to understand, use and reflect on written texts in order to achieve one's goals, to develop one's knowledge and potential, and to participate effectively in society.

Levels of reading literacy: Reading achievement was divided into five levels. Essentially, these levels represent the most difficult test items that a student could answer. Therefore, a student at one level could be assumed to be able to answer questions at all lower levels. To help in interpretation, these levels were linked to specific score ranges on the original scale. Because the five levels are complex to describe, an example from each level is given for the reading retrieving scale. Tasks of similar complexity were required for each level of the other reading scales.

Level 1 (score from 335 to 407): Students were shown a notice from a personnel department about a service that would help with job mobility. They were asked to find a single explicitly stated piece of information—how to find out more about the service—which was signalled by a heading in the text that matched the term used in the question.

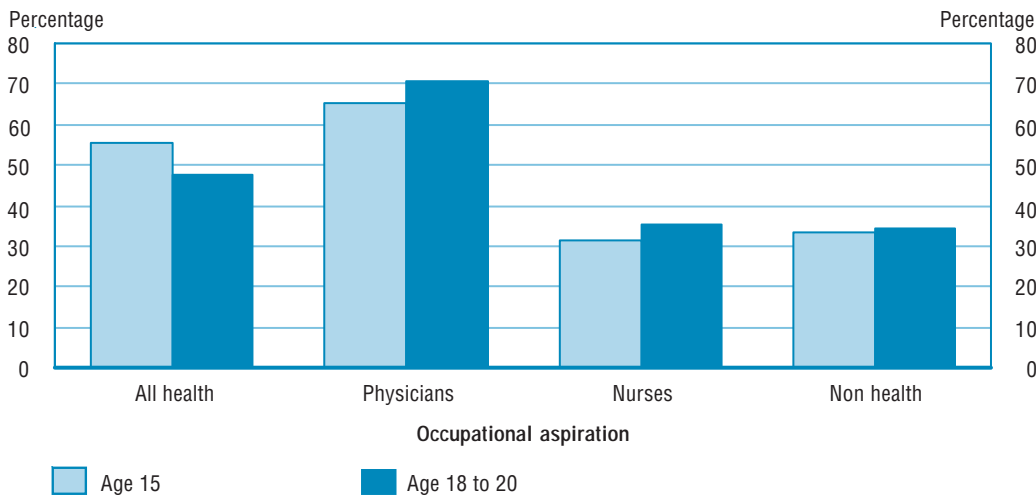

Level 2 (score from 408 to 480): Students were required to state how to check that a bicycle seat was in the right position, by finding two pieces of connected information in an assembly manual. The placement of the relevant information was clearly stated in the question.

Level 3 (score from 481 to 552): Looking at a complex international airline timetable, with prominent competing information, students had to find a single piece of information that satisfied three conditions—time, destination and connecting city. For information about one of the conditions, the reader had to refer to a separate list of abbreviations.

Level 4 (score from 553 to 626): Presented with a relatively long, dense extract from a play, students had to use information embedded in a stage direction in order to mark the positions of two actors on a diagram of the stage.

Level 5 (score above 626): Students were given a complex and unfamiliar set of instructions about how to make telephone calls from a hotel room, and a letter with the phone number of a friend in a different country. They were required to find and organise in correct sequence four pieces of information and to draw inferences to work out exactly how to dial the number.

The same story is told in the self-reported grades of youth. Over half of youth who aspire to health occupations report grades over 80%. Of those who aspire to be doctors, 65% report overall grades above 80% (compared to only 35% of youth overall). Again, however, those who say they want to be nurses tend to report lower skills with only 32% reporting 80% or over. A similar pattern can be seen for mathematics grades and for 18- to 20-year-olds (Chart 2.2, Tables 2.12, 2.13, 2.16 and 2.17).

Chart 2.2**Youth who aspire to health occupations have higher than average grades**

Note: “Nurses” refer to the Nurse supervisors and registered nurses category (e.g., nurse supervisors, registered nurses, registered psychiatric nurses, etc.), while “Non health” refers to the All other occupations category as reported in Tables 2.12, 2.13, 2.16 and 2.17.

Source: 2000 Youth in Transition Survey, Statistics Canada.

By age 18 to 20, most youth have had the opportunity to pursue postsecondary studies. Among those who aspire to health occupations, over one-third (36%) have gone on to university (compared to 25% of youth overall). Among those who say they want to be doctors, over half have already gone on to university (Table 2.18).

On measures of both academic and overall high school engagement, youth who are interested in work in health occupations are on average more engaged than youth overall. In spite of the fact that many jurisdictions now require that students complete a certain number of hours of volunteer work as part of their curriculum, the 15-year-olds aspiring to health occupations were more likely than others to volunteer during their high school years. About 70% of the 15-year-olds who aspired to health occupations report having volunteered during their last year of high school and more importantly, almost a quarter of them have done health-related volunteer work (Tables 2.19 and 2.20).

Many youth change their aspirations between the ages of 15 and 17

Most youth who aspire to health occupations say they first became interested one or more years earlier (Table 2.22). However, between the age of 15 and 17, many change their aspirations. Asked again at age 17 what job they would like at age 30, about 60% of youth cite a different occupation from the one reported at age 15 (Chart 2.3 and Table 2.23).

Chart 2.3

About half of youth who aspire to health occupations change their mind by the end of high school

Note: “Nurses” refer to the Nurse supervisors and registered nurses category (e.g., nurse supervisors, registered nurses, registered psychiatric nurses, etc.) as reported in Tables 2.23.

Source: 2000 Youth in Transition Survey, Statistics Canada.

This is also true for those who first aspired to a health occupation. Only 26% still report the same occupation; another 20% report a different occupation in health; 32% report a non-health occupation; and 22% did not respond or said they did not know. Overall, this means that almost half of the 15-year-olds who said they wanted to work in health, no longer do so. On the other hand, 8% of the population who earlier aspired to a non-health occupation have changed their minds and are now interested in health (Chart 2.3 and Table 2.23). More research is required to fully understand what are the factors related to gaining and losing interest in health occupations and whether these youth will realize their aspirations.

2.3 Learning about health occupations

Youth who aspire to health occupations are more likely to participate in career orientation activities

Little information is available on how much youth actually know about the requirements for admission to programs or how they actually learn about health occupations and the education required. However, it is clear that those who aspire to health occupations are more likely than youth overall to participate in various forms of career orientation. Most notably, they are most likely to read information about different career options (61%) and to talk to someone working in the job they are interested in (58%) (Table 2.25).

When asked what education level they think is required for the health occupation they aspire to, most youth (72%) say they believe they need one or more university degrees. This ranges from 35% of youth aspiring to technical occupations in health, 59% of those aspiring to nursing to 80% of those who aspire to medicine (Table 2.24). This is possibly a reflection of their knowledge of occupational entry requirements and the availability of training at the college level, particularly in Quebec, and for others included in nursing who expect to take nursing at the college level (who in fact aspire to be nursing assistants or licensed practical nurses) and may not know or understand the distinctions between different levels of nursing.

3. Prior learning assessment and recognition (PLAR) of foreign credentials

Immigration is an increasingly important component of net population growth in Canada. According to a report from Statistics Canada in 2001, immigration represents close to 70% of current population growth, up dramatically from under 20% in 1976. Because most immigrants enter Canada through the skilled worker immigration system, they make an enormous contribution to the pool of people in Canada with postsecondary qualifications (Canadian Labour and Business Centre 2004). It has become increasingly important, therefore, to understand how these individuals move into the Canadian workforce and especially how and if their previous credentials, skills and experience are recognized.

Prior learning assessment and recognition (PLAR) is a process that may increase immigrants' integration into their new country by increasing their employability and/or facilitating their entry into a postsecondary institution. It is a particularly important mechanism for the recognition of the international credentials of immigrants who want to work in health occupations. Within Canada, four major institutions or agencies are involved in the process of recognition of foreign credentials including: postsecondary institutions, provincial governments, professional self-regulating bodies and employers.

3.1 Data sources and methodological notes

The information used in this section comes from the first and second waves of the **Longitudinal Survey of Immigrants to Canada (LSIC)**. This survey was conducted jointly by Statistics Canada and Citizenship and Immigration Canada under the Policy Research Initiative. Designed to study the process by which new immigrants adapt to Canadian society, the survey was conducted in three waves of interviews.

The target population for the survey consists of immigrants who arrived in Canada between October 1, 2000 and September 30, 2001, were aged 15 years or older at the time of landing, and landed from abroad and applied for admission to Canada through a Canadian Mission Abroad. Interviews with these new immigrants were held six months, two years and four years after their arrival in Canada.

The sample design has been developed using a “funnel-shaped” approach—i.e. a monotonic design—therefore only immigrants that responded to the Wave 1 interview were traced for the Wave 2 interview and only those that responded to the Wave 2 interview will be traced for the Wave 3 interview. To produce reliable estimates, a representative sample of approximately 20,300 new immigrants to Canada was selected.

The topics covered by the survey include language proficiency, housing, education, foreign credentials recognition, employment, health, values and attitudes, the development and use of social networks, income, and impressions about life in Canada. The questions address respondents' situation before coming to Canada and since their arrival.

Please refer to Appendix 1 for more information on this survey.

Using information from the first and second waves of the LSIC, this analysis looks at the internationally-trained immigrants who applied with a Canadian postsecondary institution for recognition of their previously acquired academic credentials outside of Canada in the first two years after their arrival. It will look at the occupation they wanted when they decided to immigrate to Canada.

In the LSIC context, any pre-migration education above a high school diploma is considered a credential.

3.2 Characteristics of immigrants requesting PLAR at a postsecondary institution

This section examines how many immigrants with foreign credentials apply for a prior learning assessment and recognition (PLAR) at a postsecondary institution, some of their socio-economic characteristics and how successful the process is.

One third of new immigrants targeting a health occupation when they decided to immigrate to Canada asked to have their credentials checked with a postsecondary institution during their first two years in Canada

Of the 164,000 immigrants who arrived from abroad between October 2000 and September 2001, 161,000 were still living in Canada two years later. Of those, 91,000 knew what kind of job they wanted when they decided to immigrate to Canada (Statistics Canada 2005a).

Of these 91,000 immigrants who knew what kind of job they wanted when they decided to immigrate to Canada, about 6,400 (7%) targeted a health-related occupation. From those, about one-third had their credentials checked with a Canadian postsecondary institution within two years of their arrival in Canada. In the case of immigrants seeking a job in any field in general, just over a quarter (26%) requested PLAR (Table 3.1).

A quarter of immigrants seeking a health-related occupation said that lack of information on PLAR process is the main reason for not having their credentials checked

Immigrants may decide not to have their credentials checked with a postsecondary institution for different reasons. The most often stated reasons by immigrants seeking a health-related occupation was that they did not know where to go or how to get their credentials checked, they knew they would not be accepted or they did not go through this process because of time constraints. These reasons were also the most common for all immigrants who did not request PLAR (Chart 3.1 and Table 3.2).

Chart 3.1
For immigrants wanting to work in health, the main reason for not having credentials checked with a postsecondary institution is a lack of knowledge

F too unreliable to be published
 Source: Longitudinal Survey of Immigrants to Canada, Wave 2, Statistics Canada.

Three in four immigrants requesting PLAR with a postsecondary institution in the two years following their arrival in Canada and seeking a health-related occupation are women

The majority of immigrants requesting PLAR at a postsecondary institution within two years after their arrival, were men (59%). This situation is reversed among immigrants seeking for a health-related occupation. In fact, almost three-quarters (72%) of the immigrants requesting PLAR at a Canadian postsecondary institution and wanting to work in a health-related occupation are women (Table 3.3). This is not surprising given that almost three-quarters of the immigrants wanting to work in a health occupation are also women.

Medical laboratory technologists and pathologist assistants (91%) and registered nurses (88%) are the two health occupations showing the highest proportion of women immigrants compared to men immigrants (Table 3.3).

Eight in ten immigrants requesting PLAR with a postsecondary institution in the two years following their arrival and seeking a health-related occupation are between 25 and 44 and about the same proportion are married or living common-law

Two-thirds of the total pool of immigrants who arrived in Canada between October 2001 and September 2002 were aged between 25 and 44. About nine in ten immigrants of the skilled worker category were in that same age group (Statistics Canada 2005a). Therefore, it is not surprising that 84% of the immigrants who knew what occupation they were looking for before coming to Canada and who requested a PLAR at a postsecondary institution are also between 25 and 44. The

proportion is approximately the same for all immigrants requesting PLAR with a postsecondary institution (85% compared to 84%) (Table 3.4).

The proportion is the same when looking at the marital status of the immigrants requesting PLAR with a postsecondary institution. Approximately eight in ten are either married or living with a common-law partner, whether they wanted a health-related or non-health related job when they decided to immigrate to Canada (78% and 80% respectively) (Table 3.5).

Three in four immigrants who seek a health-related occupation and request PLAR from an educational institution enter Canada with education, language ability, and employment skills

The economic immigration category, which is comprised of skilled workers as principal applicants with their spouses and dependents, represents the largest group (two-thirds) of new immigrants overall. About three-quarters of immigrants who requested credential recognition with a postsecondary institution in Canada in the two years following their arrival and had targeted a health occupation were either skilled worker or the spouse or dependent of a skilled worker. Given that this group is split almost equally between skilled workers as principal applicants and their spouses and dependents, this suggests that a large proportion of principal applicants' spouses and dependents also possess education, language ability and employment skills (Table 3.6).

Categories of immigrants are defined as follows:

- **Economic class** is comprised of immigrants selected based on a number of criteria including education, language ability and employment skills (skilled workers principal applicants). Their spouse and dependants as well as business immigrants (entrepreneurs, investors and self-employed immigrants) are also part of the economic category. Two-thirds of the immigrants in LSIC are included in this category.
- **Family class** includes immigrants sponsored by close relatives or family members already living in Canada. They account for just over one quarter (27%) of the LSIC population.
- **Refugees** is comprised of Convention refugees and other refugee-like persons who are deemed to require protection of relief. Also included are resettled refugees who landed from abroad as government-assisted and privately-sponsored refugees. They account for 6% of the LSIC immigrants.
- The remaining (those not classified in one of the above categories) represents a small group of roughly 750 immigrants, and are grouped under the **Other immigrants** category.

In comparison, 19% of immigrants seeking a health-related occupation who requested PLAR from an educational institution within two years of their arrival in Canada were in the family group and the remaining 5% in the other two groups (resettled refugees and other immigrants) (Table 3.6).

Over half of the immigrants requesting PLAR with a postsecondary institution and seeking a health-related occupation come from Asia

Just over 55% of immigrants wishing to work in a health-related occupation and who applied for credential recognition with a postsecondary institution in Canada come from Asia (includes West, South and East/southeast Asian origins).

About 10% more seeking for any occupation in general came also from Asia (Table 3.7). This is reflected in the proportion of immigrants who are members of a visible minority. In fact, about three-quarters of the immigrants wishing to work in a health-related occupation and who requested PLAR at a postsecondary institution are members of a visible minority, about the same proportion (80%) as for immigrants requesting PLAR overall. Pharmacists and registered nurses are the two health-related occupations where we found the highest proportions of immigrants requesting PLAR being members of a visible minority (Table 3.8).

A majority of immigrants requesting PLAR with a postsecondary institution and seeking a health-related occupation have a high level of schooling

Given that most immigrants in Canada come through the skilled worker immigration system, it is not surprising to see that more than half (55%) of immigrants overall come to Canada with a university degree, while 19% had some postsecondary or trade diploma or certificate (including completed college) (Statistics Canada 2005a).

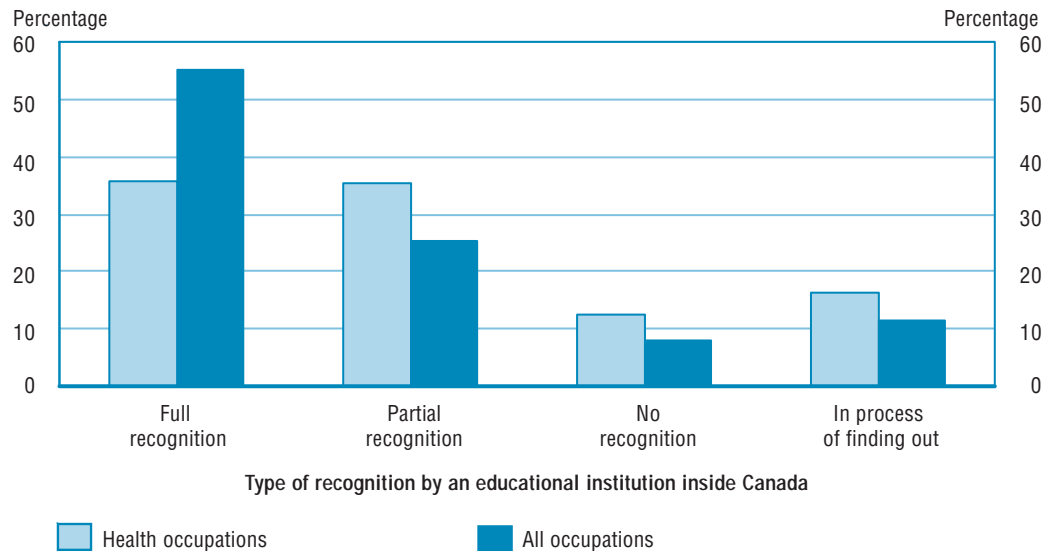

Immigrants requesting PLAR at a postsecondary education institution are more likely to have some foreign credentials, which means at least some education above a high school diploma. A large majority of immigrants requesting PLAR and seeking for a health-related occupation when immigrating to Canada have a university degree (almost 80%): 39% at the bachelor's degree and another 39% a graduate degree (master's or doctorate). As expected, more than seven in ten immigrants requesting PLAR at a postsecondary institution and wanting to work as a physician or dentist have a graduate degree. About 84% of all the immigrants requesting credential recognition have either a bachelor's (50%) or a graduate degree (36%) (Table 3.9).

Over seven in ten obtained a full or partial recognition of their credentials from a postsecondary institution within two years of immigrating

Not all immigrants requesting credential assessment at a postsecondary institution obtain a full recognition of their credentials. About a third (36%) of those wanting a job in a health-related field had gained full recognition of their foreign credentials within two years of immigrating, and another third (35%) had a partial recognition. The remaining was either refused recognition, or was still in the process of finding out. These figures are lower than for all immigrants who requested PLAR where 57% obtained a full recognition of their credentials and 24% a partial recognition (Chart 3.2 and Table 3.10).

4. Full-time faculty in university health education programs

Educators can have an impact on both the capacity and the quality of health-related programs. The lack of educators can jeopardize the number of seats available for any given programs. To better understand the nature of health education programs, some basic information on all those teaching, whether in class or in clinical settings, is required.

4.1 Data sources and methodological notes

The data in this section comes from the **University and College Academic Staff Survey (UCASS)**. This survey has been conducted since 1946 to obtain nationally comparable data concerning the socio-economic characteristics of full-time university teachers. It is conducted annually and provides a snapshot of full-time university faculty as of October 1st of each year. The target population of this survey is **full-time** educators in degree-granting institutions who have a teaching assignment and are under contract for twelve months or more. This report focuses on data from the 2003/04 academic year.

Please refer to Appendix 1 for more information on this survey.

Data is collected for the principal subject taught and therefore may not provide total coverage for individual fields of study where faculty teach in more than one principal subject. For information on the classification of courses included in each principal subject taught, please refer to Appendix 4.

Note on part-time educators

UCASS collects information on full-time university faculty only, excluded from the survey are educators at the college or CEGEP (collège d'enseignement général et professionnel) level, as well as on educators hired by universities other than on a full-time basis. The last survey conducted by Statistics Canada on part-time university educators (Part-time University and College Academic Staff Survey) was in 1997/98. According to a report by Statistics Canada in 2003, the delivery of courses by part-time educators at Canadian universities is no longer a phenomenon but a reality of university staffing. In fact, between 1990/91 and 1997/98, part-time educators hired by universities increased by nearly 10% (from 25,700 to 28,200), while full-time university faculty decreased by about 8% during the same period (Statistics Canada 2003b). This phenomenon has also been observed between 1992/93 and 2002/03, with the number of full-time university educators decreasing by about 4% (Statistics Canada and Council of Ministers of Education, Canada 2006).

It is therefore important to note that the analysis in this report is limited to full-time university faculty, and the impact of missing information about part-time and college or CEGEP educators could be considerable in terms of measuring the nature of the teaching capacity of programs.

Rounding of counts from UCASS

To be able to publish data at the most detailed level possible, the approach taken by Statistics Canada to ensure that data for individuals cannot be identified is to round data randomly to 3 (this allows the production of detailed data). The following rules are applied at the institution, province and Canada level.

All frequencies are randomly rounded to a multiple of 3 using the following procedure:

- Frequencies which are a multiple of 3 are not adjusted.
- Frequencies one greater than a multiple of 3 are adjusted to the lower multiple of 3 with a probability of two-thirds and to the upper multiple of 3 with a probability of one-third. The probabilities are reversed for frequencies one less than a multiple of 3.

For example:

Frequency	Action
27	Do not adjust as it is a multiple of 3.
28	Adjust to 27 with a probability of two-thirds or to 30 with a probability of one-third.
29	Adjust to 27 with a probability of one-third or to 30 with a probability of two-thirds.

Whenever the rounded frequency is 0 (an actual frequency of 1 or 2 which is randomly rounded to 0), it is treated the same as an actual 0 and not printed.

The use of random rounding can create slight anomalies. Since sub-totals and totals are also randomly rounded, they will not necessarily equal the sum of the randomly rounded component figures. This will likely be most evident where the frequencies are small.

For example, a sub-total may be shown even though no component figures are shown. In this case, the component figure(s) of 1 or 2 will have been randomly rounded to 0 (and thus not printed) while the sub-total will have been rounded to say 3, 6 etc. Conversely, it is also possible to have component frequencies shown but no sub-total appears.

4.2 Characteristics of full-time university faculty teaching primarily a health-related subject

The following section provides information on the socio-demographic characteristics, educational background, previous work experience, mobility, work arrangements and salaries of full-time educators teaching in Canadian public universities.

Many full-time university faculty combine teaching and practice of their health-related occupation

There are over 37,000 full-time university teachers in Canada, and one-fifth of them teach a health-related subject. It is important to note that even though UCASS collects information on full-time teachers, not all of them are assigned full-time to teaching. Depending on their work arrangement (or on their type of appointment), some educators may be engaged in the practice of a health-related occupation as well as in the teaching of a health-related subject at the university (see appointment categories below). This explains the very high number of faculty reported above. There is approximately 1,800 “regular full-time academic staff” in the health-related subjects, which account for about 5% of the total full-time university faculty (Table 4.1).

Categories of appointment are defined as follows:

- **Regular full-time (12 months) academic staff** – This is a regular academic appointment similar to that in any other faculty. The appointee receives his full salary from the institution. This category usually applies to all **basic medical science departments** and to other medical or dental staff who are not engaged in private practice. It also includes staff who are supported by research grants but whose income is administered by the university. These staff are expected to hold some teaching responsibilities.
- **Geographic full-time (12 months) academic staff** – This category applies to all medical and dental staff who are engaged in the practice of medicine as well as teaching. Geographic full-time staff members usually receive an established percentage of their regular salary from the university and the remaining portion from provincial medical care institutions (e.g., hospitals) and/or medical care plans. In addition, they are entitled to earn an income (limited by a ceiling) for service to patients. The staff members are usually assigned to a specific hospital. Although they may receive only a percentage of their income from the university, they are counted as full-time members of the institution. For the most part, clinical staff will be included in this category.
- **Full-time (12 months) joint appointments** – This category includes medical and dental staff who have received a letter of appointment from both the university and one of the teaching hospitals. Salaries are paid by both institutions at an agreed upon ratio.

Two-thirds of the full-time university faculty teaching in a health-related subject are concentrated in the teaching of medical and surgical specialties (24%), medical sciences (23%) and psychology (20%). Clinical / medical laboratory science and allied professions and health administration as the principal subjects taught are the two disciplines that have the smallest pool of full-time teachers (12 and 33 full-time teachers respectively) (Table 4.2).

Men dominate full-time university faculty especially in dentistry and medical sciences, while women prevail in nursing and occupational therapy

When looking at university teachers with health-related principal subject taught, about 62% of the full-time university teachers are men. The proportion rises to 69% for full-time faculty teaching any subject in general. The largest proportions of full-time male teachers in health-related subjects are found in the

dentistry field (79%), and in medical sciences (77%), two occupations dominated by men. The two health-related subjects that are taught mostly by women on a full-time basis compared to men are nursing (94%) and occupational therapy (85%) (Table 4.3).

Full-time university faculty teaching principally a health-related subject are aging and 31% of them continue to work after age 55

The issue of aging faculty is a central concern facing the management of universities. The group of teachers who are now preparing for retirement were hired in the 1970s, at a time of significant growth in the postsecondary system. As the youth population declined in the 1980s, slowing enrolment growth meant fewer university faculty were hired during this period. Looking ahead, large numbers of university faculty hired during the 1970s enrolment boom are in a position to retire over the next decade, at the same time that the population of 19- to 24-year-olds is projected to increase (Statistics Canada and Council of Ministers of Education, Canada 2006).

Similar to what is observed for full-time university faculty overall, the average age of the full-time teachers in health-related subjects is 49. About 37% of full-time university faculty in health-related subjects were aged 45 to 54, compared to 28% of the labour force working in health occupations. Similarly, 29% of full-time university faculty teaching principally a health-related subject were aged 55 to 64, almost three times the percentage in the health labour force (10%). About 2% of full-time university faculty teaching principally a health-related subject continue to work after age 65, compared to 1% of the labour force working in health occupations. About a quarter (26%) of full-time university faculty teaching principally a health-related subject were aged 35 to 44, compared to 31% of the labour force working in health occupations (Table 4.4 and Statistics Canada 2001a).

The average age of the full-time university faculty teaching principally a health-related subject varied between 47 and 51, with the exception of the ones teaching principally a clinical / medical laboratory science and allied professions with 43 years old on average (Table 4.2).

One in five full-time university faculty was born outside Canada

A sizable majority of full-time university teachers (83%) were born in Canada. The proportion is almost the same whether they teach principally a subject related to health (85%) or any subject in general (83%). There are, however, a few notable exceptions. Physical therapy (almost all) and nursing (93%) as the principal subject taught showed the highest proportion of full-time Canadian-born educators, while clinical / medical laboratory science and allied professions and rehabilitation showed the lowest (75% and 76% respectively) (Table 4.5).

Of the 1,100 full-time health-related university teachers born outside Canada, about three-quarters are teaching three main health-related subjects: medical sciences, followed by medical and surgical specialties and psychology (between 250 and 300 in each subject). These three subjects also hire the most full-time Canadian-born teachers, but in a slightly lower proportion (66%) (data not shown).

Most full-time university faculty have a doctorate or a professional degree

Individuals generally require a doctoral degree to be able to teach at the university level. However, this is not the case for health programs, where practical experience in the related occupation is also important. Over six in ten (63%) full-time university faculty teaching a health-related subject have a doctorate compared to almost eight in ten for all full-time university faculty. But, when adding the full-time faculty with a professional degree to the two groups, the percentage increases to 86% for the full-time teachers of a health-related subject and to 84% for the total faculty. This is not surprising given that entry-to-practice requirements for a large majority of health-related occupations do not require a master’s or a doctoral degree. The three subjects with fewest full-time teachers with a doctorate are dentistry (35%), medical and surgical specialties (43%) and nursing (45%) (Chart 4.1 and Table 4.6).

Chart 4.1

Most full-time faculty teaching principally a health-related subject have either doctoral or professional degrees

Source: 2003-2004 University and Colleges Academic Staff System, Statistics Canada.

Levels of highest earned degree are defined as follows:

- Doctoral degrees;
- Professional degrees (excluding master’s or bachelor’s degrees). Refers to medical and paramedical degrees only;
- Master’s degrees and equivalent license;
- Graduate diploma;
- Bachelors degree;
- Professional designation other than a degree;
- Undergraduate diploma;
- No degree, diploma or professional designation;
- Unknown.

The only principal subject taught with more full-time university teachers with a master's degree (47%) is nursing. Again, this may be explained by the entry-to-practice requirements for most nursing occupations do necessitate either a college or bachelor's degree (depending on the province) (Chart 4.1 and Table 4.6).

Less than one in three full-time university faculty teaching principally a health-related subject also taught in their previous employment

Attrition of faculty members may have a direct impact on the ability of a postsecondary institution to increase the size of a particular program. Over four in ten full-time university faculty (42%) remained in the same type of occupation—teaching—as their previous employment (the employment or occupation held immediately prior to the appointment (or reappointment) to the current institution). In the case of full-time university educators teaching principally a health-related subject, their previous employment was either teaching at a university or affiliated college or at an other educational institution (28%), being students (15%) or employed in a hospital, clinic or other health care unit (13%) (Table 4.7).

Overall, around 31% of full-time university faculty are working in the same province as their previous employment, and one fifth have changed provinces. This fact is true for all full-time university teachers regardless of the principal subject taught. But within health subjects, full-time teachers who taught nursing and occupational therapy as their principal subject have the lowest geographical mobility rate. About half (52% in nursing and 48% in occupational therapy) are working in the same province as their previous employment (occupation held immediately prior to his or her appointment (or reappointment) to the current institution) (Table 4.9).

On average, full-time university teachers of all subjects have been appointed to the current institution for about 13 years. Similar to what was observed for geographical mobility, full-time men teachers are more likely than their female counterparts to stay for a longer period of time within the same institution, on average 14 years compared with 10 years (Table 4.8).

The actual salaries of full-time faculty varies slightly by the principal subject taught, but men tend to have a higher salary than women

In general, the average salary of the full-time university faculty teaching principally a health-related subject exceeds the average salary of the full-time faculty of all subjects together. With an overall average of \$91,000, the average salary of full-time health-related university teachers is about \$4,000 higher than the salary of the overall full-time university educators (\$87,000) (Table 4.10).

The **actual salary** represents the actual gross salary (including vacation pay) expected during the salary year. Stipends or other honoraria for administrative duties are excluded. For medical and dental staff also working in a hospital or medical care plan, both the university contribution and the contribution by hospitals and/or medical care plans are included.

Average salaries are calculated based on exact salary figures (actual salary). In cases where the unrounded count is 3 or less, the associated mean salary figures are suppressed.

There seems to be a salary gap between men and women in the teaching occupation. Full-time male university teachers earn about \$12,000 more than their female counterparts on average across all fields. In the health-related field, the only subjects where full-time women faculty earn more money than men are clinical and medical laboratory science and allied professions, nursing and occupational therapy, where they earn, on average, \$44,000, \$7,000 and \$2,000 more than their male counterparts. In all other subjects, male teachers are more likely to have a higher salary (Table 4.10). However, given that educators in postsecondary institutions generally operate in “union” environments, the salary gap between men and women may be driven to factors such as their job tenure, highest education and previous work experiences. This difference in salary may also be attributable in part to the fact that there are considerably more men teaching dentistry, medical sciences and medical and surgical specialties which includes full-time faculty also engaged in the practice of medicine and residency supervision.

With few exceptions, full-time university faculty are mostly full professor or associate professor

Full professors and associate professors make up around 70% of full-time faculty, and another quarter or so of all full-time faculty act as assistant professors. This is true for all subjects taught except for full-time faculty teaching principally nursing, rehabilitation and clinical / medical laboratory science and allied professions where only 49% of the first two and 25% of the last are either full professor or associate professor. It is important to note that in the last subject, the number of full-time faculty is very small therefore the percentage is not as meaningful. Another 36% of nursing educators and 32% of rehabilitation teachers are assistant professor (Table 4.11).

Faculty’s ranks are defined as follows:

- **Full professor:** the most senior position.
- **Associate professors:** mid-level with requirements varying considerably between institutions and departments.
- **Assistant professor:** entry-level, never tenured, although in most institutions the term is used for tenure-track positions.
- **Rank below assistants:** lecturers or instructors.
- **Rank below preceding:** teachers below the rank of lecturer or instructors (for example, coaches).
- **Other:** ungraded staff.

5. Students in university health education programs

This section provides information on the number and characteristics of students enrolled in health programs in Canadian universities at four levels of study: bachelor's and other undergraduate degrees, master's, and doctorate levels, as well as at the residency level. A demographic profile of students is presented along the lines of sex, age, citizenship, and immigration status. The extent of full- and part-time study among health students is also examined.

5.1 Data sources and methodological notes

This analysis is based on combined data from the **University Student Information System (USIS)** and the **Postsecondary Student Information System (PSIS) (formerly known as the Enhanced Student Information System (ESIS))**. Since the early 1970s, USIS has been the vehicle used by Statistics Canada to collect data on enrolment (and graduates) from all public universities in Canada. Statistics Canada began to develop PSIS in the mid-to-late 1990s with the intention that it would replace USIS and other postsecondary enrolment (and graduate) surveys conducted by Statistics Canada in order to address the shortcomings of these surveys and to provide additional information needed by policy makers and other stakeholders. Both USIS and PSIS are censuses in that they obtain data from the administrative files of public universities on **all** students enrolled.

Please refer to Appendix 1 for more information on these two distinct surveys.

In 2000, phased implementation of PSIS began across Canada. Universities that have not yet implemented PSIS continue to use USIS as their data reporting mechanism. In 2004/05, the latest year for which university data are available, 63% of public universities, representing nearly 56% of university enrolment, were reporting using PSIS.

Each year, the number of institutions reporting through PSIS increases.

Information on the number and characteristics of students enrolled in health education programs in Canadian universities is broken-down according to the following **levels of study**:

- **Bachelor's and other undergraduate degrees:** includes bachelor's, first professional and applied degree programs;
- The **master's level** includes all programs so named;
- The **doctorate level** includes students in doctorate of philosophy (Ph.D.) programs and equivalent earned doctorates; and
- The **residency level** covers students in medical and dental residency programs.

University enrolment data from the combined USIS and PSIS data collection provide a snapshot as of December 1 of the academic year.

Note on USIS and PSIS data limitations

Because USIS collects less information than does PSIS, only a small set of common variables are available from the combined USIS and PSIS dataset. In addition, the field of study data collected in USIS is much less detailed than that of PSIS. PSIS classifies field of study according to the Classification of Instructional Programs (CIP 2000) (see Appendix 3), which has some 1,200 categories, while USIS has only about 200 categories. It is for this reason that in this study, the analysis of health programs is at the 4-digit level of CIP.

It is important to emphasize that enrolment information from USIS and PSIS provided in this report is limited to the public university sector. It does not include college data, nor does it include information from private postsecondary institutions.

All students taking for-credit courses are included in the enrolment data, including those who are not seeking a degree, diploma or certificate. Universities currently do not report the distinction between students enrolled in credit programs who are seeking a degree, diploma or certificate and those who are taking for-credit courses without seeking certification in a program. Those who are taking for-credit courses without seeking certification in a program may be doing so for personal or professional development reasons. Students taking non-credit courses are not included in the data as universities do not report these students to Statistics Canada.

A consequence of these limitations is that the enrolment information in this report does not reflect the entirety, complexity or variety of education and training available to each of the health occupations, especially in nursing. In other words, there are individuals in health programs from colleges and private postsecondary institutions that are not reflected in this report. Please refer to Appendix 6 for more details on the impact of these data limitations in relation to nursing programs.

Enrolment data for medical (M.D.) programs and medical residency programs presented in this report are not consistent with those that are published by the Association of Faculties of Medicine Canada and the Canadian Post-M.D. Education Registry, respectively. It is intended that future work will be undertaken to better understand these inconsistencies.

5.2 Enrolment in university health education programs

Enrolment information provided in this section gives an indication of the volume of activity taking place in the different health education programs and the relative size of these programs in the university system.

Health students represented between 6% and 8% of enrolment at the bachelor's and other undergraduate degrees, master's, and doctorate levels of study, with nursing among the largest programs at each of these three levels of study

In 2004/05, there were approximately 46,700 students enrolled in health programs in Canadian public universities at the bachelor's and other undergraduate degrees

level, representing about 7% of enrolment at this level. Students pursuing health programs accounted for a similar proportion of the student body at the master's (8%) and doctorate (6%) levels (Table 5.1).

By far, the largest health program at the bachelor's and other undergraduate degrees level was nursing, which accounted for slightly more than half of all enrolment in health programs. Medicine (M.D.) was a distant second, accounting for 17% of all enrolment in health programs, followed by pharmacy, pharmaceutical sciences and administration accounting for 9% of students (Table 5.1).

About 7,400 students took health programs at the master's level in 2004/05. The three largest health programs at the master's level were nursing, (28% of this student body), rehabilitation and therapeutic professions (20%), and public health (15%) (Table 5.1).

The total health program enrolment at the doctorate level was about 1,900 students, with the medical scientist program making up about 26% of this number, and public health and nursing each accounting for another 16% (Table 5.1). Medical scientists programs are clinical science programs that prepare graduated physicians (M.D.s) as research scientists in various areas.

In addition to students in health programs, a substantial proportion of students pursued selected health-related programs

In addition to those students pursuing health programs, there were also a substantial number of students enrolled in the selected health-related programs covered in this report (i.e., psychology, social work, and health and physical education / fitness).

Students enrolled in any one of the selected health-related programs accounted for 9% of bachelor's and other undergraduate degrees enrolment, 7% of master's enrolment, and 9% of enrolment at the doctorate level (Table 5.1).

It is worth noting that there were large numbers of students pursuing biological and life sciences programs, such as for example, biology, biotechnology, and genetics, who may or may not eventually move into the health fields. Students in related biological and life science programs or other natural sciences are not examined in this report.

5.3 Characteristics of students enrolled in university health education programs

In general, women continue to make up the overwhelming majority of health students in Canadian universities

Traditionally, women have been the majority in most health occupations (Galarneau 2003) and in those education and training programs leading to these positions. In Canadian public universities in 2004/05 this was still generally the case.

In health programs, women accounted for four out of every five students at the bachelor's and other undergraduate degrees (81%) and master's levels (79%), and almost two-thirds (63%) of enrolment in health programs at the doctorate level. Women have a greater presence in health programs than at these three levels of study in general. Women accounted for 58% of all students at the bachelor's

and other undergraduate degrees level, 53% of all master's students, and 46% of doctoral students (Chart 5.1 and Table 5.2).

Chart 5.1

Women make up the majority of health students

Source: University Student Information System (USIS) and Postsecondary Student Information System (PSIS), Statistics Canada.

Women make up at least half of the student body in almost all health programs at each level of study, although there is some variation in their representation across programs. Dentistry — traditionally a male-dominated field¹ — enrolled the lowest proportion of women than any other health program at the bachelor's and other undergraduate degrees level (52%). The presence of women in dentistry declines as the level of study increases. At the master's level, women accounted for 43% of students taking advanced/graduate dentistry and oral sciences, while they accounted for only 38% of enrolment in this program at the doctorate level (Table 5.2).

Women also make up more than half of all students in medicine (M.D.) programs at the bachelor's and other undergraduate degrees level. Their percentage representation in this field, 59%, is in line with their overall representation at the undergraduate level².

Undergraduate students taking health programs are usually older

At the bachelor's and other undergraduate degrees level of study, students aged 24 and younger are considered to make up the typical university-going cohort. Although there is no difference in the average age of health students as compared to all bachelor's and other undergraduate degree students (the average age of both groups is 21), a much larger percentage of health students are older than the typical university-going cohort. In 2004/05, about 40% of health students were older than 24 years of age compared to 19% of all bachelor's and other undergraduate degrees students (Chart 5.2 and Table 5.3).

The age profile of health students at the bachelor's and other undergraduate degrees level of study is influenced by the comparatively high proportions of older students in nursing and medicine, the two largest health programs at the

bachelor's and other undergraduate degrees level. About 42% of nursing students were 25 years of age and older in 2004/05, as were 46% of students in medicine (M.D.). This higher than average proportion of students aged 25 and over in medicine is likely related to the fact that a bachelor's degree is the typical prerequisite for entrance into the program, which means that students are not entering medicine until their mid-20s. In medicine, examining changes in the number of students with graduate degrees upon entry would further help to explain the makeup of the student body in terms of age. In the case of nursing, the ability to disaggregate the enrolment in bachelor's and other undergraduate degrees in terms of entry-to-practice programs (i.e., programs enabling successful graduates to apply for initial licensure) and post-registered nursing programs (programs for registered nurses already in the workforce who want to obtain their degree) would go some way in explaining the age structure of the nursing student body (Table 5.3).

At the master's level in 2004/05, slightly over half (54%) of health students were under 30 year of age, 27% were between 30 and 39 years, and 20% were 40 and older. On average, health students at the master's level were 32 years old. When compared to master's students in all programs, health students had a similar age profile (Chart 5.2 and Table 5.4).

However, when individual health programs are looked at, some programs stand out as the age profile of their students is substantially different from those of all health students taken together. Among the larger health programs at the master's level (measured by enrolment size), students in communications disorders sciences and services; pharmacy, pharmaceutical sciences and administration; and rehabilitation and therapeutic professions were much younger than health students in general. About four out of five students in each of these programs were younger than 30 years of age. On average, students were 26 or 27 years old in these programs.

In contrast, nursing stood out as having a substantially older age profile than other health programs. In 2004/05, the average nursing student at the master's level was 38 years old. A little less than half (45%) of all nursing students at the master's level were 40 years of age and over, with another one-third of student being between the ages of 30 and 39 (Table 5.4).

At the doctorate level, 40% of students in health programs were under 30, 37% were in between the ages of 30 and 39, and 24% were 40 and older. The average age of health students at the doctoral level was 34, whereas the average doctoral student was 33 year of age. Health students were more likely to be older than 40, but less likely to be in their 30s as when compared to all doctoral students (Chart 5.2 and Table 5.4).

Medical scientists were much more likely to be younger than their health student counterparts at the doctoral level. The average age of students in medical scientist programs was 31, with 51% of these students being younger than 30 while only 11% were 40 and over. Again nursing students were different than health students in general, as the average age of a doctoral nursing student was 43. Over two-thirds of doctoral nursing students are over the age of 40 (Table 5.4).

Chart 5.2

Health students are more likely to be older particularly at the bachelor's and other undergraduate degrees level

Source: University Student Information System (USIS) and Postsecondary Student Information System (PSIS), Statistics Canada.

International students are defined as non-Canadian students who do not have “permanent resident” status and have had to obtain the authorization of the Canadian government to enter Canada with the intention of pursuing an education. In other words, international students are those who have come to Canada expressly to pursue their education.

Canadian students include Canadian citizens as well as permanent residents.

International students account for a smaller proportion of the student body in most health programs

While the proportion of international students in health programs increases somewhat with the level of study, the proportion of international students in health programs is always lower than the proportion of international students in all programs. This smaller presence of international students in health programs than in general may be related to restrictions on the number of seats in Canada available for international students as well as the lack of ease of transferability of some health programs across borders.

In 2004/05, there were about 700 international students enrolled in health programs at the bachelor’s and other undergraduate degrees level, representing about 2% of the total number of health students at this level of study. At the bachelor’s and other undergraduate degrees level as a whole, the proportion of international students was also small (6%) (Chart 5.3 and Table 5.5). With some exceptions, the proportion of international students does not vary much across the individual health programs. Some of the smaller health programs enrolled a somewhat higher proportion of students from abroad than average. However the actual number of international students enrolled in these programs was small (Table 5.5).

Overall at the master’s level in 2003, there were about 400 international students enrolled in health programs, making up about 6% of the student body in health programs. This compares to about 13% of the entire student population at the master’s level (Chart 5.3 and Table 5.5).

There were slightly more than 200 international students studying health programs at the doctorate level, accounting for about 12% of all students in health programs at this level. At the doctorate level as a whole, the proportion of international students was 22%, a higher level of representation than in the health programs at this level of study (Chart 5.3 and Table 5.5).

At the master’s and doctorate levels, the absolute numbers of international students were small even in those programs with higher proportions of international students.

Chart 5.3**International students make up a smaller proportion of the student body in health programs than in all programs**

Source: University Student Information System (USIS) and Postsecondary Student Information System (PSIS), Statistics Canada.

Country of citizenship: Students with a citizenship other than Canadian comprise both international students as well as permanent residents who have come to live in Canada as a result of immigration—by themselves or by their parents. The Canadian citizen category includes both Canadian citizens by birth and those who were born outside Canada, immigrated to Canada and became Canadian citizens by naturalization.

Non-Canadian citizens are less likely to be found in health programs at all levels of university study

At all levels of study, the proportion of Canadian citizens enrolled in health programs is higher than in all programs, thus indicating that non-Canadian citizens are less likely to be found in health programs. At the undergraduate level, 94% of students in health programs were Canadian citizens, compared to 88% of students in all programs (Table 5.6).

At the master's level, 87% of student taking health programs were Canadian citizens, compared to 75% of students in all programs. At the doctorate level, 75% of health students were Canadian, compared to 62% of all students (Table 5.6).

Most students in health programs are enrolled full-time at rates similar to the general student population

In 2004/05, slightly over 80% of students in health programs at the bachelor's and other undergraduate degrees level were studying on a full-time basis. The incidence of full-time study in health programs is no different than that among the bachelor's and other undergraduate degrees population as whole (85%) (Table 5.7).

Full-time students were the overwhelming majority in just about all health programs at the bachelor's and other undergraduate degrees level. Among the larger health programs (measured in terms of enrolment), nursing showed slightly

more of a mix between full- and part-time students than health programs in general. In nursing, almost 30% of students were enrolled on a part-time basis, almost double the proportion in health programs overall. Further research would be of interest to determine to what extent nursing students in entry-to-practice programs³ are pursuing their program on a part-time basis as compared to those who are in programs intended to service those already qualified nurses who want to upgrade their qualifications to a baccalaureate (Table 5.7).

At the master's level, 69% of students were pursuing health programs on a full-time basis. Inversely, this means that about one-third of students (31%) in health programs at this level were pursuing their studies on a part-time basis. About the same proportion of master's students in all programs was registered as part-time students (Table 5.7).

However, when individual health programs are looked at, in all but three programs—nursing, public health, and bioethics/medical ethics—the proportion of students studying on a part-time basis is much lower than the average for all health programs taken together. Nursing at the master's level is predominately a part-time program with about two-thirds of students taking the program on a part-time basis (Table 5.7).

On average almost all students, 91%, were pursuing their doctorate in health programs on a full-time basis. This is in line with the overall enrolment pattern at this level where 93% of students are enrolled full-time in their programs (Table 5.9). There was not much variation across individual health programs at this level of study in terms of the proportion of students studying on a full-time basis (Table 5.7).

6. Graduates from health education programs

This section presents information about the period immediately following graduation. It includes information on the characteristics of graduates, student loans and satisfaction with their program. In all models of health human resources planning, new graduates are a major source of supply into health occupations. Thus, monitoring the number and characteristics of health graduates is an important part of health human resources planning.

6.1 Data sources and methodological notes

The **National Graduates Survey (NGS)** is used in this section for data pertaining to socio-demographic characteristics (such as sex, age, immigration status, citizenship, language of conversation, marital status and designated groups⁴), activities prior to graduation, satisfaction of graduates and student loan information. The National Graduates Survey (NGS) is designed to measure the short to medium-term labour market outcomes of graduates from Canadian public universities and community colleges. It is produced every four to five years and the last available data is for the class of 2000.

The target population for this survey are all persons from Canadian public postsecondary education institutions (universities, colleges, trade schools) who graduated or completed the requirements for degrees, diplomas or certificates during 2000. Excluded are: graduates from private postsecondary education institutions; completers of continuing-education programs (unless these led to a degree, diploma or certificate); part-time trade course completers; persons who completed vocational programs lasting less than three months; persons who completed vocational programs other than in the skilled trades (e.g. basic training and skill development); completers of provincial apprenticeship programs and those living outside of Canada or the United States at the time of the survey.

NGS is a sample survey with a cross-sectional design and a longitudinal follow-up. In all, 38,483 usable interviews were obtained from the initial sample of 61,558, from which 2,898 units were deemed out-of-scope, for a response rate of 65.6%.

Please refer to Appendix 1 for more information on this survey.

6.2 Characteristics of graduates from health education programs

Health graduates accounted for 7% of bachelor graduates and 14% of college graduates in 2000

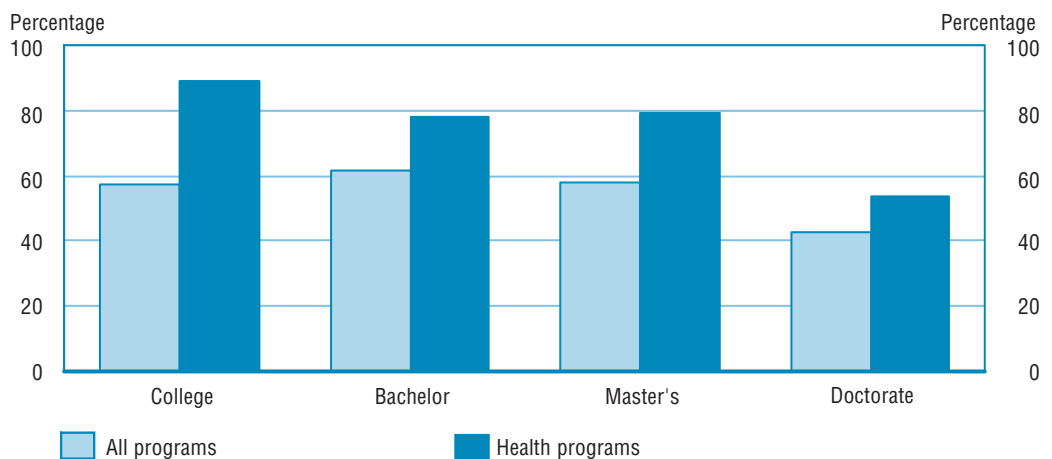

In 2000, there were approximately 270,000 graduates from Canadian public colleges and universities (bachelor, master’s and doctoral graduates). Graduates from health programs at the college level accounted for 14% of the estimated 100,000 graduates, while graduates from bachelor health programs represented about half as many as in college (7% of the 130,000 bachelor graduates) (Table 6.1 to Table 6.5).

Health graduates are generally more likely to be women

The majority of health graduates are women, and the proportion of all health graduates who are female is higher than that of all graduates. Overall, about 60% of college and bachelor graduates in 2000 were women. In health programs, these proportions increase to nearly 90% for college graduates and 80% for bachelor graduates. About 60% of all master’s graduates were women, but 80% of health graduates at this level were women. Finally, about 40% of doctoral graduates were women, compared with more than half of health graduates (Chart 6.1 and Table 6.1 to Table 6.5).

Chart 6.1

Graduates from health programs are more likely to be women

Source: National Graduates Survey (Class of 2000), Statistics Canada.

College and bachelor health graduates are older and more likely to be married

College and bachelor health graduates tend to be older than graduates overall. At the college level in 2000, the average age of health graduates was about 30, compared with 27 for all graduates. At the bachelor level, the average age of health graduates was 28, compared with 26 for all graduates (Table 6.6 to Table 6.10).

Possibly because they are older than graduates overall, a greater proportion of college and bachelor graduates from health programs were married by two years after graduation. Nearly half of health graduates were married compared with about a third of all graduates. At the master's and doctoral levels, just as there is little difference in age, there is also no difference in marital status (Table 6.11 to Table 6.15).

In terms of designated groups, graduates from health programs are no more and no less likely than all graduates to be Aboriginal, members of visible minorities or to have activity limitations. The only exception to this pertains to doctoral graduates from health programs, who are slightly less likely to be members of visible minorities when compared with graduates from all programs (13% compared with 19%) (Table 6.16 to Table 6.20).

The majority of health graduates can speak English well enough to conduct a conversation, but less than a third can do the same in French

Providing health services in both official languages is of particular concern to provinces which are bilingual, or offer bilingual services because of high proportions of French-speaking people in their population. Thus, it is important to examine the ability of graduates to conduct conversations in both official languages. The majority of graduates, including health graduates, indicate they could speak English well enough to hold a conversation. However, fewer of them express the same ability in French, and health graduates are slightly less likely than all graduates to feel they have that ability. In all, about 90% of graduates across all levels of study can converse in English, compared with about 30% of health graduates and 40% of all graduates who can converse in French.

Language in which a conversation can be conducted is based on the respondent's feeling of his or her ability to hold a conversation in the two official languages, while **mother tongue** refers to the first language learned at home in childhood and still understood by the individual.

While the attached tables using the National Graduates Survey contain both mother tongue data (Table 6.26 to Table 6.30) and data on the language in which a conversation can be held (Table 6.21 to Table 6.25), only the latter is presented in the text, as it more closely offers an estimation of the potential ability to provide services in an official language; while mother tongue may still be understood, it does not necessarily mean that individuals also have the ability to communicate in the language.

In spite of this, a different picture emerges when examining the results by level of study for those who are able to maintain a conversation in French. First, the ability to speak French tends to increase with the level of study, and this is particularly evident for health graduates. While about 20% of college health graduates are fluent in French, this increases to about 40% at the bachelor and master's level and 75% at the doctoral level. About half of graduates from all programs at the doctoral level reported that they were able to conduct a conversation in French (Table 6.21 to Table 6.25).

Many, but not all, graduates able to hold a conversation in French graduated from Quebec institutions. At the college level, more than half of graduates who indicated being able to converse in French were graduates from Quebec institutions, and about 60% of doctoral graduates from all programs indicating the same ability

were graduates from Quebec institutions. In contrast, at all levels, nearly all graduates from Quebec institutions indicated they were able to conduct a conversation in French.

Where do college and bachelor health graduates who can hold a conversation in French live two years after graduation?

About half of the college and bachelor health graduates who can hold a conversation in French can be found in Quebec, and another quarter in Ontario. Small proportions of graduates can also be found in Nova Scotia, New Brunswick, Alberta and British Columbia. Overall, Nova Scotia and Quebec contribute less health graduates with the ability to converse in French than would be expected by their proportion of the population with the same ability, while Ontario and Alberta generally contribute more.

Table A
Province of residence of the college and bachelor health graduates who can hold a conversation in French

	College graduates	Bachelor graduates	2001 population
	% with the ability to converse in French		
Nova Scotia	3	3	1
New Brunswick	4	3	3
Quebec	57	51	73
Ontario	26	25	15
Alberta	4	5	2
British Columbia	3	6	3

Sources: National Graduates Survey (Class of 2000), Statistics Canada and calculations from the 2001 Census, Statistics Canada.

The ability of workers in health occupations to speak an Aboriginal language is an important health care issue as well. While some medical interpreters are available, particularly in Nunavut, communication problems still remain, which can make Aboriginal people uncomfortable and make diagnoses challenging (NAHO 2003). Difficulties in medical interpreting can occur, for example, in cases where there are no commonly-accepted terms for medical illnesses and concepts in a particular Aboriginal language or across dialects, and in some cases where the medical interpreters or health professionals lack an understanding of the social construction of illness in a community. Thus, it is important to monitor how many new health graduates have the ability to speak an Aboriginal language, particularly for regions where the first language is different from French and English. However, relatively few graduates, whether in health or not, express the ability of being able to hold a conversation in an Aboriginal language. In fact, less than 1% of graduates at the college and bachelor level indicate this ability. On the other hand, it is approximately the same proportion as graduates who indicate an Aboriginal language as their mother tongue (Table 6.31 to Table 6.33), similar to the profile of the Canadian population in general according to the 2001 Census data (Statistics Canada 2002).

The **immigration status** is the “student” status during graduates’ postsecondary training. Graduates were either Canadian or international students during their studies (Table 6.34 to Table 6.38).

Citizenship, on the other hand, is either the country of birth or the country where permanent residency is granted (citizenship by naturalization). Thus, non-Canadian students include both international students as well as residents who do not have a permanent residency status to live in Canada (Table 6.39 to Table 6.43).

The National Graduates Survey (NGS) does not interview American citizens who returned to their country nor graduates who are living outside of Canada or the United States at the time of the interview. Thus, international students who return to their country of origin after they complete the requirements of their program are not part of the scope of the survey. As a consequence, the proportion of Canadian students and Canadian citizens is likely to be over-estimated. For this reason, the data is shown in the tables, but is not presented in the text.

Health graduates at the bachelor level are the most likely to use some form of distance education during their studies

On-campus, scheduled classroom learning may disadvantage certain groups such as parents who must juggle both work and child care responsibilities and people living in rural or remote communities. Distance education can be seen as a method of increasing accessibility for all (Townsend et. al. 2002). The National Graduates Survey collects information on whether graduates followed at least part of their program using some form of distance education. In general, bachelor graduates are about twice as likely as college and master’s graduates to indicate some use of distance education during their program (about 20% compared with nearly 10%). And it is only at the bachelor level that health graduates seem able to take advantage of this possibility in greater numbers than graduates in general. About 25% of bachelor graduates from health programs indicated that they completed their degree using some form of distance education, compared with 20% of graduates from all programs. There are no differences between health graduates and all graduates at the college, master’s or doctoral levels. The differences by level may be attributable to an availability of more distance education courses in health programs at the bachelor level, but it is not possible to verify this for this study (Table 6.44 to Table 6.48).

College and bachelor health graduates are more likely to have some previous postsecondary education

Pathways into health education appear complex. Both college and bachelor graduates from health programs are more likely than graduates from all programs to have some previous postsecondary education. Nearly half of college health graduates and nearly three-quarters of bachelor health graduates have some previous postsecondary education, compared with about one third of college graduates from all programs and nearly half of all bachelor graduates.

College and bachelor health graduates are also more likely to have completed their previous postsecondary education. In fact, at the college level, about three health graduates in ten had a previous postsecondary degree, diploma or certificate, compared with two in ten of all graduates. At the bachelor level, the proportions are higher: just over half of all health graduates completed postsecondary previously, compared with four in ten of graduates from all programs. It should

be noted that Quebec bachelor graduates in all fields have generally completed previous postsecondary education at the college level because of the nature of the education system and the role of Collèges d’enseignement général et professionnel (CEGEP).

However, within individual health programs, there are some further differences. At the college level, graduates from a number of health programs were more likely to have completed previous postsecondary when compared to graduates from all health programs.⁵

At the bachelor (or first professional degree) level, health graduates from the dentistry and medicine programs were more likely to have completed a previous postsecondary program, when compared to all health graduates, but graduates from nursing / registered nurse, pharmacy, pharmaceutical sciences and administration were less likely. This may be attributable to the fact that programs such as medicine often require a previous degree as part of their admission requirements. Then again, health graduates from the pharmacy programs were just as likely as graduates from all health programs to have some postsecondary education (whether completed or not) whereas nursing graduates were less likely (Chart 6.2 and Table 6.49 to Table 6.57).

Chart 6.2
Health graduates are more likely to have some previous postsecondary education

Source: National Graduates Survey (Class of 2000), Statistics Canada.

College and bachelor health graduates have longer previous full-time work experience

While college and bachelor health graduates in general are no more likely than graduates in general to have full-time work experience prior to their graduation, their amount of experience is higher. This is likely related to the fact that they are older.

College health graduates have an average of about 7 years of prior full-time work experience, compared with 6 years for all graduates. At the bachelor level, health graduates have nearly 6 years of prior full-time work experience, compared with 4.5 years for their counterparts from all programs. However, about 5% of college and bachelor health graduates had their last significant full-time work experience—full-time work experience that lasted at least six consecutive months with the same employer—prior to graduation in a health occupation, while nearly 10% master’s and doctoral health graduates make this claim (Table 6.58 to Table 6.67).

6.3 Student debt of graduates from health education programs

Financial barriers are one of many barriers to access and participation in postsecondary education. Financial barriers can consist of price constraints (the cost of education does not appear worth the benefit), cash constraints (inability to raise sufficient funds) and debt aversion (reluctance to incur debt) (Junor et. al. 2004). A look at education-related data from the National Graduates Survey provides some indication of the level of student indebtedness and the ability of graduates to repay that debt.

Information on education-related loans in the National Graduates Survey (Class of 2000)

Graduates were asked if they ever borrowed money to finance any of their education through a government-sponsored student loan program. They were then asked how much they owed for all their government-sponsored student loans at the time of graduation (for all programs). In addition, graduates were asked if they had ever borrowed for their education from other sources that they would have to pay back (such as private bank loans or family), and how much they owed to these sources at the time of graduation. Because some students may have borrowed and paid off loans from previous postsecondary programs prior to graduating from their most recent program, this analysis focuses only on those graduates who reported an amount owing upon graduation. The analysis is also restricted to those graduates who have not pursued any additional education and who have thus been required to pay off their loan in the two years since graduation.

Graduates who owed money for their education to any source (government or non-government): Includes graduates who owed money to government-sponsored student programs, to other sources or to both sources.

Graduates who owed money for their education to government student loan programs: Includes graduates who owed money to government-sponsored student programs, whether or not they owed money to other sources.

Graduates who owed money for their education to non-government sources: Includes graduates who owed money to other sources, whether or not they owed money to government-sponsored student loans.

Graduates who owed money for their education only to government student loan programs: Includes graduates who owed money to government student loans but excludes graduates who also owed money to other sources.

Graduates who owed money for their education only to non-government sources: Includes graduates who owed money to other sources but excludes graduates who also owed money to government-sponsored student loans.

Graduates who owed money for their education to both government student loan programs and to non-government sources: Includes graduates who owed money to both sources but excludes graduates who owed only to a single source.

Bachelor and doctoral health graduates are more likely to have education-related loans than graduates overall and their debt level is higher

At the bachelor and doctoral level, health graduates are more likely than all graduates to owe money to any source (whether government student loans or some other source) and their debt is also higher. This also holds true whether the debt is in the form of student loans, other loans, or both, although more owe to government-sponsored student loans. At the bachelor level, nearly 60% of health graduates owed to some education-related loan, with an average amount owing of nearly \$31,000 to all sources. In comparison, a little more than half of graduates from all bachelor programs owed money, with an average of a little more than \$20,000. At the doctoral level, nearly three-quarters of health graduates owed an average of \$38,000 to all sources, compared with nearly half of all doctoral graduates, with an average amount owing of nearly \$24,000.

Patterns for owing just to government-sponsored student loans and owing just to other sources are similar, but in lower proportions and amounts owing. Higher proportions of health graduates owing higher amounts of loans, particularly at the bachelor level, is possibly due to the fact that they are more likely to have previous postsecondary education (often because it may be a requirement to enter the program), thus increasing the number of years where education-related loans may be necessary (Table 6.68 to Table 6.97).

In spite of this, bachelor health graduates are less likely than graduates from all programs to report difficulties in repaying their government-sponsored student loans. About 14% of health graduates from the bachelor level report difficulties in repaying their government-sponsored student loans, compared with 24% of

bachelor graduates from all programs. A large part of this may be due to the fact that their earnings are higher than graduates from all programs (see Section 7.2) (Table 6.98 to Table 6.102).

As well, in spite of higher debt levels, health graduates from all levels are just as likely to repay their government-sponsored student loans within the first two years after graduation, as evidenced by the fact that a similar proportion of them are out of debt two years after graduation, when compared to their counterparts from all programs. Overall, about one in five graduates repay their government-sponsored student loans within the first two years after graduation. Finally, they were also as likely to believe that their government-sponsored student loans would be paid off within five years after graduation (Table 6.103 to Table 6.107).

6.4 Satisfaction and plans of graduates from health education programs

Satisfaction of graduates with their program is likely an indication that institutions meet students' needs. In addition, when graduates are satisfied with their programs, they become advocates of that program and institution. Such advocacy can help in the recruitment of students into health programs.

The majority of health graduates are satisfied with their program

Satisfaction among graduates in terms of their program is fairly high. About 80% of all graduates, including health graduates, indicated that if they could go back in time, they would still select the same type of program. Doctoral health graduates, in particular, are slightly more likely to have higher levels of satisfaction, when compared to their counterparts from all programs. About 93% of doctoral health graduates expressed satisfaction, compared with 84% of doctoral graduates from all programs.

There is little variation in satisfaction among individual health programs. Only physicians and physical therapy / therapist from the bachelor level are more satisfied than all health graduates (Table 6.108 to Table 6.112).

3. Excludes Preveterinary studies.

4. Includes veterinary programs but excludes all health programs, Psychology, Social work, Epidemiology and Health and physical education / fitness.

5. These health programs are special groupings from health programs above. They were selected as they represent the priority occupations as determined from the health human resources and education consultations conducted in 2005 (see Allen et. al. 2006). Physicians are comprised of Medicine and Medical residency programs.

6. Not a standard Classification of Instructional Programs (CIP) category.

Note: Type of program is defined using the Classification of Instructional Programs (CIP). See Appendix 3 for more details.

7. Activities after graduation

Using the National Graduates Survey (NGS), this section examines transitions into the labour market of health graduates, including work activity, earnings and pursuit of additional education. The focus is on the short-term outcomes (about two years after their graduation in 2000) as a measure of graduate transitions. For more information on the National Graduates Survey, please refer to “Data sources and methodological notes” in Section 6.1 and to Appendix 1.

7.1 Pursuit of additional education (including graduate studies) after completion of a health education program

Obtaining additional education can have a significant payoff for individuals in the labour market, particularly where the entry-to-practice requirements necessitate higher levels of education. In some cases, however, health graduates who pursue additional education may mean a short or long-term loss in the supply of direct care health practitioners, as they either steer away from health occupations in general or direct themselves into teaching, research or policy work. The knowledge of the level of pursuit of additional education thus becomes important information for recruitment and retention in health occupations.

Health graduates are generally less likely to pursue additional education than graduates overall

Many graduates have some previous postsecondary education prior to their current program, and many go on to new programs with their recently acquired degrees and diplomas. However, with the exception of doctoral health graduates, health graduates in general are less likely to pursue additional education after their graduation, when compared with graduates from all programs. At the college level, about 20% of health graduates pursue additional education, compared with 25% of graduates from all college programs. At the bachelor level, about 25% of health graduates do so, compared with about 40% of all bachelor graduates. Finally about 20% of master’s health graduates pursue additional education, compared with 30% for all graduates at this level. These results may in part be due to the fact that health graduates in general are more likely to have some postsecondary education experience previous to their current program. A second reason may be due to the fact that many health programs are occupation-oriented, so that additional education may not be seen as necessary in order to obtain employment after graduation.

There are, however, differences within individual health programs, when compared to graduates from all health programs. Most notably, at both the college and bachelor level, graduates from health services / allied health / health sciences, general, were the most likely to pursue additional education. Programs in this category generally prepare individuals for either entry into specialized training

programs or for a variety of concentrations in the allied health area; its very nature, therefore, explains why many graduates from this program pursue additional education.

At the bachelor level, graduates from communication disorders sciences and services are also more likely to pursue additional education, while graduates from rehabilitation and therapeutic professions are the least likely. For graduates from communication disorders sciences and services, the higher proportion who go on to further education is likely due to the fact that audiologists and speech-language pathologists need a master's degree to work in their occupation and those who wish to pursue research in communication disorders either need a master's or a doctorate (Table 7.1 to Table 7.5).

7.2 Labour market outcomes of graduates from health education programs

The success of health graduates in the labour market can indicate whether they will remain in the occupation in the long-term. Thus, information on the short-term outcomes of graduates can also lead to important information for recruitment and retention.

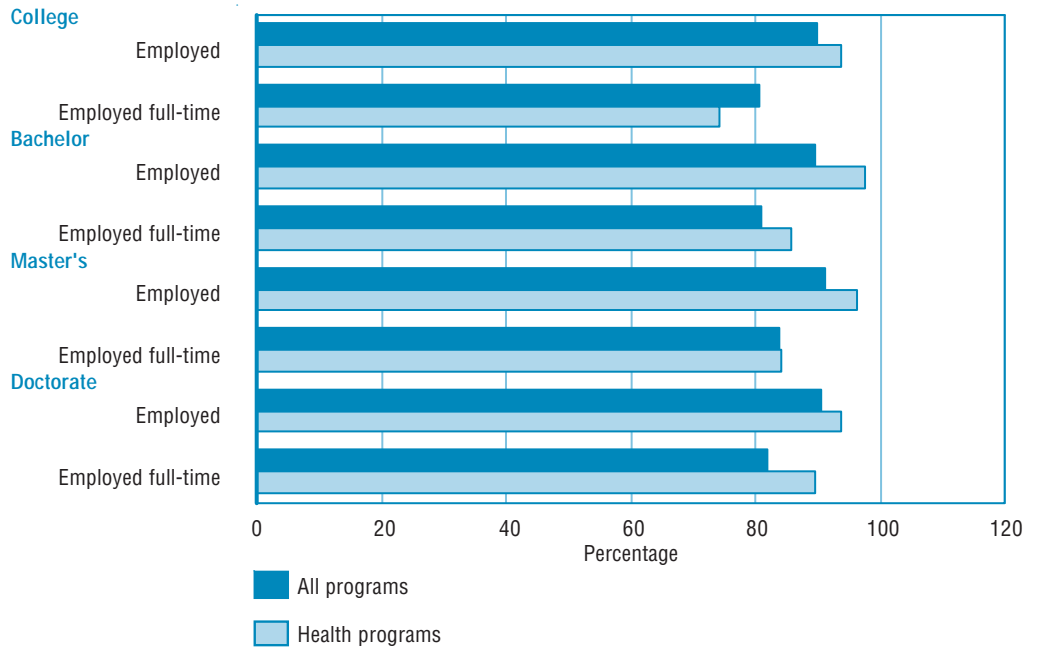

Taking additional education after their graduation has an impact on the labour market outcomes of graduates two years later. Graduates who complete additional education may have a higher level of education than the one obtained in 2000, and so may have different labour market experiences than those of the same level in 2000 who do not continue on to additional education. At the same time, however, graduates who pursue further education, whether they have completed it or not, may not have been in the work force as long as those graduates who do not and may still be enrolled. Finally, graduates who are still enrolled two years after graduation may or may not be working or looking for work. Therefore, these graduates' outcomes are likely to be affected by this pursuit of education, and not be comparable to those with similar levels of study from the class of 2000. For these reasons, all those who pursued additional education after their 2000 graduation are excluded from the analysis of outcomes in the labour force. This analysis therefore reflects direct labour market transitions of graduates into the work force with no further studies.

At most levels of study, health graduates are more likely to be employed and in a full-time position

At all levels of study except doctoral, health graduates are slightly more likely to be employed two years after graduation than their counterparts from other programs. About 90% of graduates from all programs at the college, bachelor and master's level are employed two years after graduation, compared with 94%, 98% and 96% respectively for health graduates.

With 74%, college-level graduates are less likely than their counterparts in all programs (81%) to be employed full-time (work at least 30 hours per week) two years after graduation. The situation is reverse at the bachelor and doctoral levels, where about nine in ten graduates from health programs are working full-time compared with about eight in ten overall. At the master's level, however, health graduates are no more likely than graduates overall to be working at least 30 hours per week (84% respectively) (Chart 7.1 and Table 7.6 to Table 7.15).

Chart 7.1
In general, health graduates are more likely to be employed and in full-time positions

Source: National Graduates Survey (Class of 2000), Statistics Canada.

Most college and bachelor health graduates work in health occupations

It is also very important to know whether graduates from health programs work in health occupations. About three-quarters of college health graduates and 83% of bachelor health graduates are employed in a health occupation two years after graduation. Some health programs, such as mental and social health services and allied professions programs at the college and bachelor levels and public health programs at the bachelor level, have lower proportions of graduates working in health occupations. This is partly a reflection of the fields themselves. For example, mental and social health services programs train for many of the counselling positions, such as in substance abuse, community health services, pastoral, marriage and genetic counselling. Many of these positions are not classified as “Health occupations” using the National Occupational Classification Statistics (NOC-S); they are found mostly in the “Occupations in social science, education, government service and religion” grouping. In fact, nearly three-quarters of bachelor graduates and about half of college graduates from these programs work in the occupations found in this grouping.

By the same token, public health programs encompass a variety of programs such as environmental health, health / medical physics, occupational health and industrial hygiene, public health education and promotion, community health and preventive medicine, maternal and child health, international public health / international health and health services administration. As with mental health occupations, this type of training may not lead to the traditional occupations found in the health classification (NOC-S). In fact, 40% of graduates from these programs work in natural and applied sciences and related occupations compared with 20% in the health occupations.

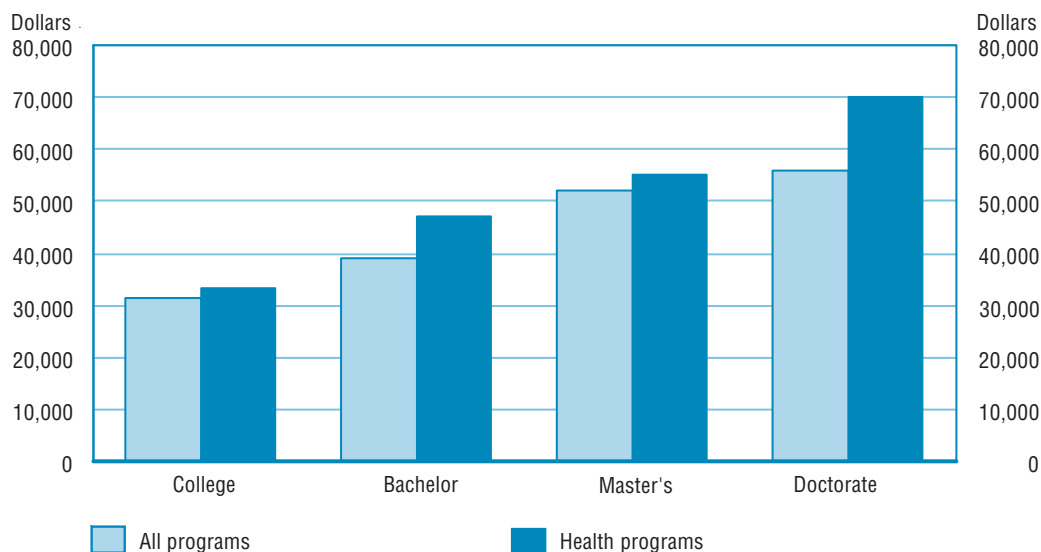

Health programs at the master's and doctorate levels also have lower proportions of graduates working in health occupations two years after graduation (about three in five, compared with four in five for lower levels). About 20% of these graduates have an occupation from the "Occupations in social science, education, government service and religion" grouping, indicating that higher levels of education may lead to more diverse types of occupations, due to a focus in research, consultation or policy and program work as well as teaching (Table 7.16 to Table 7.20).

Two years after graduation, most health graduates earn more than graduates overall

With the exception of master's graduates, health graduates earned more two years after graduation than graduates from all programs. In addition, for both health graduates and all graduates, earnings increased with the level of study. The estimated median earnings of college health graduates was \$33,000 annually, compared with about \$31,000 for college graduates from all programs. At the bachelor level, health graduates earned approximately \$47,000, compared with about \$39,000 for all graduates. Graduates from all programs including health programs at the master's level earned between \$52,000 and \$55,000 annually. Finally, doctoral health graduates earned about \$70,000, compared with approximately \$56,000 for graduates from all programs (Chart 7.2 and Table 7.21 to Table 7.25).

Chart 7.2

Health graduates working full-time generally earn more than graduates from all programs two years after graduation

Source: National Graduates Survey (Class of 2000), Statistics Canada.

Information on earnings is for graduates working full-time who have not pursued or completed any additional education. Earnings information is calculated from the salaries and wages of graduates who were working full-time (30 hours or more) in the week prior to the survey and assumes that they worked for the entire year.

The analysis of earnings uses medians to present the typical earnings of graduates. “Median earnings” is the amount which divides the top earning graduates (50%) from the lower earning graduates (50%).

University health graduates are not more likely to hold multiple jobs

There is a common belief that new graduates often work in multiple jobs in order to make ends meet because of the inability to find full-time and permanent work. This belief seems to hold true particularly in the health occupations. The National Graduates Survey asks graduates whether they have more than one job in the week prior to the interview.

Overall, by level of study, graduates from all programs are just as likely as health graduates to have more than one job about two years after graduation. The only exception pertains to college health graduates, who are more likely than their counterparts from all programs to hold more than one job two years after graduation (Table 7.26 to Table 7.30).

Doctoral health graduates are just as likely to have French as English as the main language used on the job

English is the most common language used on the job for both health graduates and graduates from all programs. Overall, regardless of level of study, four in five graduates use English as the main language at work, compared with less than one in five who use French.

However, a different picture emerges when looking at the sub-groups by level of study. At the doctoral level, health graduates are just as likely to use French as they are to use English—about half of doctoral health graduates indicated that they use the two official languages on the job. In comparison, only about 20% of doctoral graduates from all programs indicate French as the main language used on the job (Table 7.31 to Table 7.35).

8. Supply of continuing education in workplaces

The ability and willingness of adults to continue learning throughout their lives has been identified as a critical element in Canada's economic future. The need for new skills in the economy has had a profound impact on jobs, in most, if not all, industries and occupations. Traditionally, many of these new skills would have been provided by "new" workers, both young adults and immigrants entering the labour force. However, the demographic reality is that smaller cohorts of young workers will be entering the workforce and, as the work force ages, the potential for skill shortages grows. The "upskilling" of workers already in the labour force is widely seen as an important measure to meet these needs (Peters 2004).

Recognizing this need for ongoing learning, employers often encourage and support continuing education. This is particularly true in health occupations where regulatory frameworks often require ongoing maintenance or upgrading of skills. The following section presents the characteristics of workplaces (also called locations) which supported training (both classroom and on-the-job training) during 2003.

8.1 Data sources and methodological notes

The data in this section comes from the 2003 **Workplace and Employee Survey (WES)**. This survey consists of two components: (1) a workplace survey on the adoption of technologies, organizational change, training and other human resource practices, business strategies, and labour turnover in workplaces; and (2) a survey of employees within these same workplaces covering wages, hours of work, job type, human capital, use of technologies and training. The result is a rich source of linked information on workplaces and their employees.

WES is a sample survey with a longitudinal design. The target population for the employer component is defined as all business locations operating in Canada that have paid employees in March, with the exceptions of employers in Yukon, Nunavut and Northwest Territories, and employers operating in crop production and animal production, fishing, hunting and trapping, private households, religious organizations and public administration.

The initial sample selected in 1999 is followed over time and is supplemented at two-year intervals with a sample of births selected from units added to the Business Register since the last survey occasion. In 2003, 6,565 locations were interviewed.

The target population for the employee component, on the other hand, is all employees working or on paid leave in March in the selected workplaces who receive a Canada Customs and Revenue Agency T-4 Supplementary form. The frame of the employee component of WES is based on lists of employees made available to interviewers by the selected workplaces. A maximum of twenty four employees are sampled using a probability mechanism. In workplaces with fewer than four employees, all employees are selected. Employees will be followed for two years only, due to the difficulty of integrating new employers into the location sample as workers change companies. As such, fresh samples of employees will be drawn on every second survey occasion (i.e. first, third, fifth). In 2003, 20,384 employees were interviewed.

The WES includes several questions on training. The employer questionnaire asks about training supported (provided, funded or assisted) by the workplace during the period from April 1, 2002 to March 31, 2003, while the employee survey asks about training taken in the twelve-month period prior to the interview.

Please refer to Appendix 1 for more information on this survey.

8.2 Characteristics of workplaces supporting training activities for their employees

It is generally recognized that in order to participate fully in the process leading to innovation within a firm, workers must not only acquire strong basic knowledge through the education system but also need to have opportunities to acquire training in the labour market (Turcotte et. al. 2003).

During 2003, about 60% of the workplaces in the health care and social assistance sector supported both classroom and on-the-job training for their employees, about the same as in the other industrial sectors (56%) (Chart 8.1 and Table 8.1). It should be noted that, in addition to workers in health occupations, workplaces in the health care and social assistance sector may also be employing individuals in non-health occupations, and this fact is consequently reflected in the statistics which are specific to the workplace.

Three-quarters of the innovative workplaces in the health care and social assistance sector support training activities for their employees

Not surprisingly, workplaces who introduced innovations⁶ between April 2002 and March 2003 were more likely than non-innovating workplaces to support training activities. While about three-quarters of the innovative workplaces in the health care and social assistance sector supported training in 2003, this was the case for about half for those who did not introduce new products, services or processes, or improved them during that same year.

Chart 8.1
Workplaces who introduce innovations are more likely than others to support training activities

Note: “Other sectors” represents all other sectors of activities (excluding the health care and social assistance sector).
Source: 2003 Workplace and Employee Survey, Statistics Canada.

Locations from the Health and social assistance sector

Although WES covers locations—also referred to as workplaces in this report—of all sizes for industries in the non-agricultural sector,⁷ analysis is only performed on those from the Health care and social assistance sector. (Please refer to Appendix 5 for more information on locations in the Health care and social assistance sector (NAICS 62).)

Locations represent the target population for the employer component of WES survey. They are defined as producing units at a single geographical location where economic activity is conducted and for which, at a minimum, employment data are available (e.g. plants, factories, mines, warehouses, stores, airports, movie theatres or hospitals). More information on the distinction between “enterprise”, “company”, “establishment” and “location” are available in Appendix 7.

In the 2003 WES, there were approximately 446 locations (or workplaces) selected from the Health care and social assistance sector in Canada, with most of them centred in Quebec (26%), Ontario (25%) and British Columbia (14%). About 22% of the workplaces were found in the Prairies, and Atlantic got the remaining (13%).

Around 43% of these locations (or workplaces) were classified in ambulatory health care services subsector (NAICS 621), 20% in hospitals (NAICS 622), 19% in nursing and residential care facilities (NAICS 623), and 18% in social assistance (NAICS 624).

The majority (53%) of these workplaces were classified as small workplaces (fewer than 20 employees), followed by large workplaces comprised of 500 employees or more (18%), workplaces of 100 to 499 employees (16%), and workplaces of 20 to 99 employees (14%).

In WES, **formal or classroom training** is defined as job-related training activities (orientation for new employees, managerial / supervisory training, professional training, apprenticeship training, sales and marketing training, computer / hardware / software training, group decision-making or problem-solving, team-building, leadership and communication training, etc.) with a predetermined format, predefined objectives, specific content and for which progress can be monitored or evaluated.

On-the-job training is defined as job-related training that involves little or no reliance on predetermined guidelines for its organization, delivery or assessment. Unlike formal training, on-the-job training is not specifically defined in the WES questionnaires.

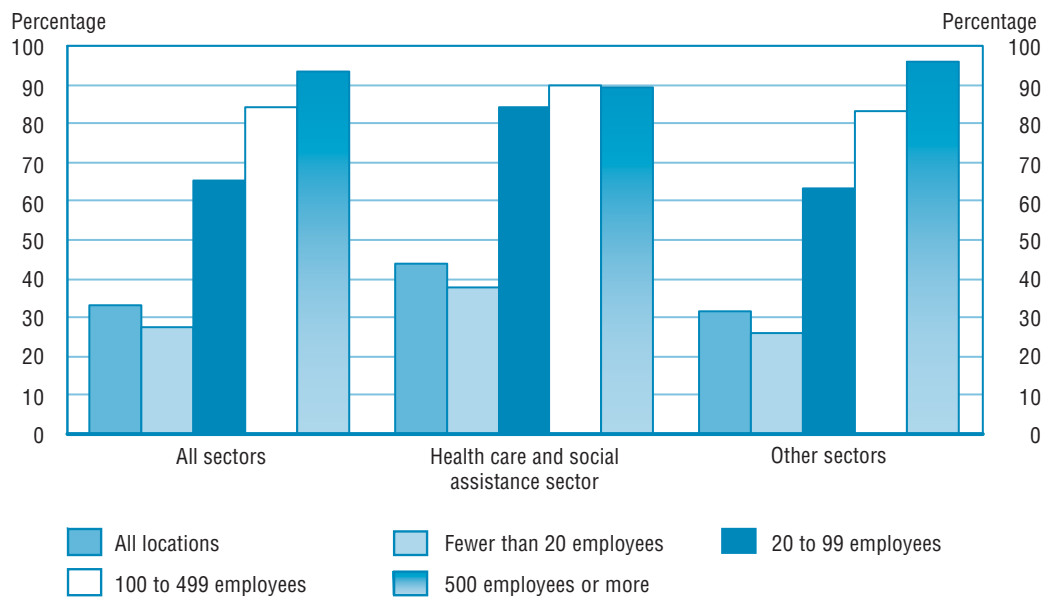

The **size of a workplace** (or location) is based on the number of employees as follows:

- workplaces with fewer than 20 employees;
- workplaces with 20 to 99 employees;
- workplaces with 100 to 499 employees; and
- workplaces with 500 employees or more.

Support for formal training is higher in the health care and social assistance sector than elsewhere and increases with the number of employees

About 40% of the workplaces in the health care and social assistance sector supported formal training in 2003. By comparison, this was the case for less than a third for workplaces operating in other sectors of activities (Chart 8.2 and Table 8.2). The proportion of workplaces in the health care and social assistance sector supporting formal training were highest (about 90%) for those with 100 or more employees, and declined for each successive location size, to about 40% for the smallest workplaces (locations with less than 20 employees).

Chart 8.2
Support for formal training increases with the number of employees

Note: "Other sectors" represents all other sectors of activities (excluding the health care and social assistance sector).
Source: 2003 Workplace and Employee Survey, Statistics Canada.

A variety of types of formal training were offered by workplaces in the health care and social assistance sector during 2003. Professional training, orientation for new employees, and training on occupation health and safety and environmental protection were among the most common types of formal training offered by these workplaces during that year (Table 8.3).

A greater proportion of employees from the health care and social assistance sector are participating in formal training

Not only are workplaces in the health care and social assistance sector more likely than those in other sectors to support formal training, but a greater proportion of their employees are also participating in those training activities (Chart 8.3 and Table 8.3). Workplaces in the health care and social assistance sector reported that, on average, about half of their employees were participating in formal training during 2003 (11 employees out of 22 on average). This compares to slightly less than 40% of the employees for workplaces in other sectors of activities (six employees out of 16 on average).

Chart 8.3

On average, one in two employees from the health care and social assistance sector is participating in formal training activities

Note: "Other sectors" represents all other sectors of activities (excluding the health care and social assistance sector).
Source: 2003 Workplace and Employee Survey, Statistics Canada.

Most of the formal training is taken within the working environment, often offered by an outside trainer

More than half of the employees in professional (55%) and technical (59%) occupations in health reported taking their formal training within their working environment during 2003. By comparison, this was the case for a third (33%) of employees in other occupations related to health (managers in health care, medical secretaries, inspectors in public and environmental health and occupational health and safety, psychologists, and social workers) (Table 8.4).

During that same year, more than half of the employees in professional (53%), technical (58%) and other (52%) health occupations reported taking a course offered by an outside trainer, and most of them reported taking such formal training during their normal working hours (Table 8.4).

Support for on-the-job training is about the same as for formal training for locations in the health care and social assistance sector

About half of the locations in the health care and social assistance sector supported informal on-the-job training during 2003, about the same proportion as for locations operating in other industrial sectors (Chart 8.4 and Table 8.5).

Chart 8.4
Support for on-the-job training is about the same as for formal training for locations in the health care and social assistance sector

Note: “Other sectors” represents all other sectors of activities (excluding the health care and social assistance sector).
 Source: 2003 Workplace and Employee Survey, Statistics Canada.

However, contrary to the other sectors where the support for on-the-job training (48%) was higher than for classroom training (32%), the support for on-the-job training (48%) for locations in the health care and social assistance sector was only slightly higher than the one for more formal types of training (42%) (Chart 8.4, Tables 8.2 and 8.5).

In the health care and social assistance sector, the most common form of informal training is “orientation for new employees”

The most common type of on-the-job training offered in the health care and social assistance sector during 2003 was orientation for new employees, supported by two-thirds of employers (Table 8.6). Computer and software training, professional training, team building, leadership and communication training, and training on occupation health and safety and environmental protection were also among the most common types of informal training offered by this sector of activities during that year.

During 2003, about 40% of the employees from professional occupations in health taking on-the-job training reported a “supervisor” as being their training provider. About 30% reported that such type of training was either offered by an “in-house trainer,” an “outside trainer,” or a “fellow worker” (Table 8.7).

Similar to what was observed with formal classroom training, location size (as measured by the number of employees) seems to have an impact on the support for on-the-job training (Chart 8.5 and Table 8.5). In 2003, the proportion of workplaces in the health care and social assistance sector supporting on-the-job training were highest (about 97%) for those with 100 or more employees, and declined for each successive location size, to about 42% for the smallest workplaces (locations with less than 20 employees).

Chart 8.5
Support for on-the-job training increases with the number of employees

Note: "Other sectors" represents all other sectors of activities (excluding the health care and social assistance sector).
 Source: 2003 Workplace and Employee Survey, Statistics Canada.

Workplaces in the health care and social assistance sector are more likely to subsidize or reimburse their employees for the training they took outside

About half (47%) of the workplaces in the health care and social assistance sector reported subsidizing or reimbursing their employees for the classroom training they took outside the workplace (Table 8.3). By comparison, this was the case for about a third (33%) of workplaces operating in other sectors of activities.

This support was given despite the fact that about six in ten workplaces in the health care and social assistance sector did not receive any external funding (federal/provincial government programs, training trust funds, union or employees association funding, industry organizations, employees, equipment vendors, other private sector organizations, other outside sources of funding) for the formal training they offered to their employees during 2003 (Table 8.3). It is worth noting that many workplaces in the health care and social assistance sector are primarily publicly-funded and that funding for their employees' training may already be included in their budget.

Money received from provincial government programs was the most popular source of external funding as reported by 19% of workplaces in the health care and social assistance sector for formal training offered to their employees during 2003 (Table 8.3). Money received from employees was also reported by about 16% of these workplaces. By comparison, only 5% of the workplaces operating in other industrial sectors reported these sources of funding.

Table 8.1
Percentage of workplaces supporting training (classroom and/or on-the-job), by innovation status, sector of activities and size, Canada, 2003

9. Participation in continuing education

Lifelong involvement in learning is important for many reasons. With advances in health care knowledge and technology, it is particularly important that adults from health occupations be able to maintain and upgrade their skills and knowledge through continuing education. It is useful to understand who is participating in training and learning activities (whether formal or informal) and the role their employers play in supporting this training, as well as what kind of training they are getting. Knowledge of both formal and informal training provides a more complete picture of the activities in which workers are involved as they develop their job skills. It also offers insight into whether workers are combining their formal training with informal learning, or if these two types of training are used by different groups of workers.

9.1 Data sources and methodological notes

The data in this section comes from the 2003 **Adult Education and Training Survey (AETS)**. This survey was designed to update knowledge of the job-related training and education activities of Canadians. The primary objectives of the AETS were to measure participation in job-related education and training, to provide a socio-demographic profile of individuals who participated in these activities, to profile the type, duration, location and other characteristics of the training activities, and to identify the barriers to, and outcomes of, training activities.

The target population of this survey is defined as people 25 years of age and over living in the ten provinces, excluding inmates of prisons, patients of hospitals, residents of long-term care facilities, residents of Indian reserves, and full-time members of the armed forces. Respondents were asked a series of questions about their training and education activities in 2002.

Information was collected from 25,056 adults, which corresponds to approximately 0.12% of the target population in 2003. A sample of this size permits the production of relatively detailed estimates at the national and provincial levels.

Please refer to Appendix 1 for more information on this survey.

9.2 Characteristics of adults participating in continuing education

Information on both types of training (formal and informal) provides a more complete picture of the activities in which adults are involved as they develop their job skills. It also offers insights into whether adults are combining their formal training with informal learning, or if these two types of training are used by different groups of workers.

A large proportion of adults from health occupations participate in formal training or informal learning

In 2002, 537,000 adults from health occupations participated in either formal or informal job-related training, representing about two-thirds (65%) of Canadians aged 25 to 64 in those occupations (831,000) (data not shown). With about 60% involved in formal job-related training and more than half (54%) participating in informal learning during that same year, this seems to indicate that a large proportion of adults from health occupations were combining the two types of training (Chart 9.1, Tables 9.1 and 9.17).

Chart 9.1

A large proportion of adults from health occupations participate in formal training and/or informal learning

Source: 2003 Adult Education and Training Survey, Statistics Canada.

For the purpose of this report, **adults from health occupations** are defined as individuals aged 25 to 64 who were working at some point in 2002 (as employee or self-employed) and whose main job (that is, the job at which they worked the most hours) was related to health (please refer to Appendix 2 for more details on occupations related to health).

Formal job-related training includes courses or programs related to a worker's current or future job. These courses and programs, either supported or not by an employer, have a structured plan whereby a student, led by a teacher or trainer, follows a planned program and receives some form of formal recognition upon completion, such as a certificate, diploma or degree.

Formal, job-related courses include seminars, workshops and conferences attended for training purposes, as well as courses which are taken for reasons other than credit in a program.

Informal job-related training or self-directed learning: The 2003 AETS asked respondents if they had done any of a series of activities either for the purpose of developing job skills or to gain job-related knowledge. These activities include: seeking advice from someone knowledgeable, using the Internet or other software, observing someone performing a task, consulting books or manuals, or teaching themselves different ways of doing certain tasks.

To aid accurate recall of these activities, respondents were asked if they had engaged in any of these activities during the four weeks preceding the survey. In comparison, respondents were asked to report participation in formal job-related activities over the course of 2002. As a result, participation rates for these two forms of job-related training are not directly comparable.

Adults from health occupations have higher rates of participation in both formal and informal job-related training than those in all occupations

During 2002, an estimated 498,000 adults from health occupations were involved in formal job-related training, representing slightly less than two-thirds (60%) of Canadians aged 25 to 64 in those occupations (Chart 9.1 and Table 9.1). This percentage indicates that adults from health occupations participated in formal job-related training at about twice the rate observed for all occupations (30%).

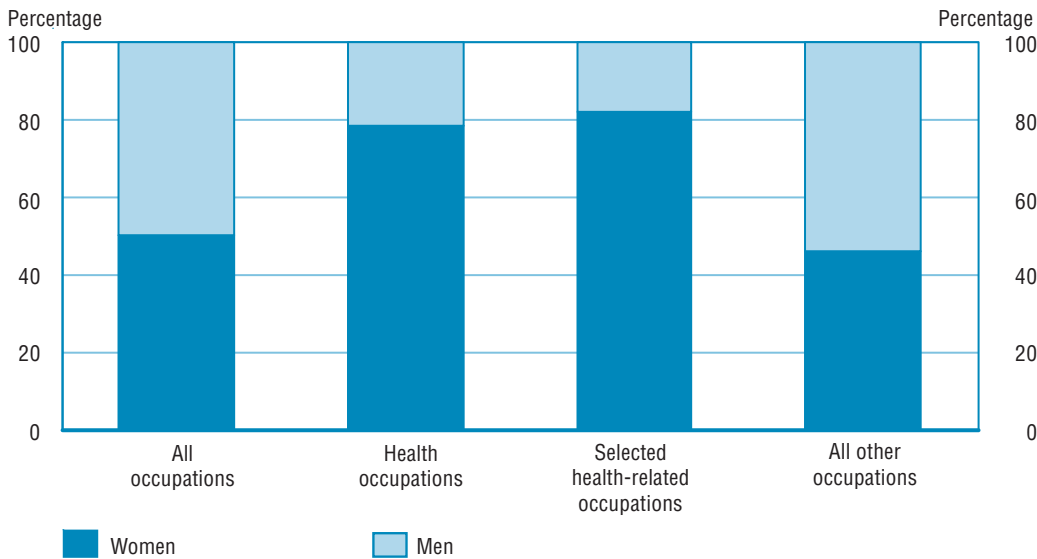

In addition, an estimated 432,000 adults from health occupations developed some of their job skills through self-directed training, representing about half (54%) of the Canadians aged 25 to 64 in health occupations (Chart 9.1 and Table 9.17). This compares to about one-third for adults in all occupations (33%). This high involvement in formal and informal training activities by adults from health occupations stands out from all others in the area of adult education and training and seems to indicate a standard in this sector of activities.

More than three-quarters of adults working as specialist physicians (88%), general practitioners and family physicians (86%), and as head nurses and supervisors (77%) participated in self-directed training during 2002. On the other hand, slightly less than a third of those in assisting occupations in support of health services (30%) (including dental assistants, nursing aides and orderlies, and other aides and assistants in support of health services) undertook such training activities during that year (Table 9.17).

Reflecting the composition of health workers, most participants in continuing education are women, but men and women are equally likely to participate in formal training

Reflecting the fact that women make up 79% of those employed in health occupations, about eight in ten (79%) adults from these occupations involved in formal job-related training were women (Chart 9.2 and Table 9.2). There are only a few exceptions where the majority of participants in formal job-related training were not women: for general practitioners and family physicians (36%) and specialist physicians (41%), there were fewer women than men participating in such training.

Chart 9.2
Most participants in continuing education are women

Source: 2003 Adult Education and Training Survey, Statistics Canada.

Although the incidence of women in job-related training was higher than the one of men in most health occupations (Table 9.2), there was no statistically significant difference in the participation rate of men and women in such training (men from health occupations were just as likely as the women to participate in the training) (Chart 9.3 and Table 9.5).

Chart 9.3
Men and women are equally likely to participate in formal training

Source: 2003 Adult Education and Training Survey, Statistics Canada.

While participation in job-related training tends to decline with age in the total population, there was no significant decline for those in health occupations

Adults from health occupations who participated in formal training tended to be older than participants overall; 40% of participants from health occupations were 45 to 64 years old compared to 35% from occupations overall (Chart 9.4 and Table 9.2). As with sex, these results reflect the labour force where about 40% of adults working in health occupations are 45 to 64 years-old (Statistics Canada 2001a).

Chart 9.4

Adults from health occupations participating in formal training tend to be older than participants overall

Source: 2003 Adult Education and Training Survey, Statistics Canada.

Although the proportion of adults participating in formal job-related training was about the same across the age groups for all occupations (Chart 9.4 and Table 9.2), participation in such training within each age group was highest for the 25- to 34-year-olds (40%), and declined for each successive age group, to 24% for the oldest workers (45- to 64-year-olds) (Chart 9.5 and Table 9.6). Adults from health occupations did not follow this pattern; participation rates were high for all age groups (between 56% and 66%) and there was no statistically significant difference in participation between the different age groups. This may be attributable to the fact that, independently of their age, health professionals are required to earn credits throughout their career if they wish to maintain their registration, professional designation or membership. The availability of training might also play a large role as both the supply of, and demand for, training services will affect the participation rates.

Chart 9.5**Participation rates of adults from health occupations were high for all age groups**

Source: 2003 Adult Education and Training Survey, Statistics Canada.

Participation rate of adults born outside Canada is two times higher in health occupations than elsewhere

Not surprisingly, a small proportion of adults from health occupations involved in formal job-related training are born outside Canada (23%) (Table 9.2). This reflects findings from the 2001 Census which show that about 18% of the total Canadian population was born outside the country (Statistics Canada 2003a).

Although the incidence of adults born outside of Canada in job-related training is lower than the one of Canadian-born in most health occupations (Table 9.2), there was no statistically significant difference between their rates of participation in training (64% compared with 59%) (Table 9.7).

The participation rate of adults born outside Canada was, however, more than two times higher in health occupations than the one observed in all occupations (Table 9.7). In fact, out of the 173,000 adults from health occupations born outside Canada, about 64% were involved in job-related training in 2002. This compares with about 26% for adults born outside Canada in all occupations.

Adults from health occupations involved in formal job-related training are more educated than average and their participation rates are higher at all levels of education

In 2002, slightly more than 90% of adults from health occupations involved in job-related training had a postsecondary certificate, diploma or university degree (Table 9.3). This compares to about eight in ten (83%) for all occupations. As previous surveys and studies have found, education is strongly linked to participation in training; the higher the level of formal education a person has, the more likely it is that he or she will participate in job-related training (OECD 2003; Belanger et. al. 1997). Given the high levels of education in health occupations, this appears to be a major factor in their high levels of participation in training.

However, regardless of level of educational attainment, adults from health occupations were more likely to participate in formal job-related training (Table 9.8). Among adults with a master's or a doctoral degree, those from health occupations (75%) were more likely than the ones in all occupations (50%) to participate in formal job-related training. This was also true among adults with a bachelor's degree (69% compared with 47%) or a postsecondary certificate or a diploma (59% compared with 35%).

Adults from health occupations are more likely to participate in training no matter what their work status is

There were proportionally the same proportion of adults from health occupations employed full-time (74%) as in all occupations (77%) (Table 9.4). In fact, similar to what was observed for all occupations, about three-quarters of adults from health occupations involved in job-related training were employed full-time in 2002. However, about twice the size of participants from health occupations are part-time workers, while those from other occupations are more likely to be unemployed.

Adults from health occupations are more likely to participate in training no matter what their work status is (Table 9.9). Generally, participation in training tends to decline with the number of hours of work; full-time workers are the most likely to take training and unemployed adults the least. In health occupations, however, there was no significant difference in the participation rates of full-time workers, part-time workers, and those who were unemployed. In fact, half of the unemployed adults from health occupations participated in training in 2002, compared to only 14% of adults in all occupations.

Although more likely to take training, adults from health occupations spend the same number of hours in formal job-related training as participants overall

Training intensity measures the amount of time participants devote to training, in terms of hours. It is an important and complementary measure to the participation rate (Tables 9.12 to 9.16). In 2002, adults from health occupations involved in formal job-related training received an average of 162 hours of training (Table 9.12). This converts to about 27 days of training, based on a training day of 6 hours. Adults from all occupations devoted an average of 176 hours to training, but this difference was not statistically significant.

Men and women spent an equal amount of time in such training (Table 9.12). There was no statistically significant difference between time devoted by men and women in such training.

Although not more likely to participate in training, the youngest group of adults from health occupations devoted the most time to training in 2002 (Table 9.13). Across the age groups, average hours of training in 2002 were highest (294 hours per participant) for the youngest group (25 to 34 years old) of adults working in health occupations, and declined to slightly more than 100 hours for the two oldest age groups.

Few courses are taken through distance education

Attending classes can be challenging for adults in demanding occupations and for those with family commitments. Increasing numbers of adults, including those working in health occupations, are turning to distance education for access to learning opportunities and continued workplace training. Adults who seek employment advancement, career changes, managerial skills, professional and personal development can continue to work and study on their own time. Distance education can also help adults pursue learning interests outside of work (Poscente 2004).

In 2002, an estimated 55,000 formal job-related courses were taken through distance education by adults from health occupations (data not shown), representing about 6% of the total number of courses taken by Canadians aged 25 to 64 from those occupations during that same year (953,000) (Tables 9.27 and 9.28). This proportion was similar to the one observed for all adults.

Adults from health occupations who participated in self-directed training have a similar profile to those who took formal training

Adults from health occupations who participated in self-directed training had similar characteristics to those who took formal training (Tables 9.17 to 9.25). Similar to what was observed for adults involved in formal job-related training, although the incidence of women in self-directed training was higher than the one of men for most health occupations (Table 9.18), there was no statistically significant difference between participation of men and women in such training (Table 9.21).

As was the case for formal job-related training, adults working in health occupations were more likely than those in all occupations to participate in self-directed learning (Table 9.21). This was true for each level of educational attainment (master's or doctoral degree, bachelor's degree and certificate or diploma) (Table 9.24).

Moreover, about 60% of adults employed full-time in health occupations developed some of their job skills through self-directed training, while participation in such activities for those working part-time was slightly less than 50% (not statistically different) (Table 9.25).

“Consulting documents” is the most popular form of self-directed learning used by adults from health occupations

While all forms of self-directed learning were popular among those who participated in this form of training, one form in particular—consulting documents (87%)—had a very high participation rates among adults from health occupations (Chart 9.6 and Table 9.26). Adults from health occupations involved in self-directed learning were less likely to report using the Internet or computer software (48%) or observing someone performing a task (55%) when they set out to learn something on their own.

Chart 9.6

“Consulting documents” is the most popular form of self-directed learning used by adults from health occupations

Source: 2003 Adult Education and Training Survey, Statistics Canada.

Four in ten adults from health occupations participate in employer-supported training

The support of an employer can mitigate many of the factors that impede training, such as cost, demands of the workplace and family responsibilities. Adults from health occupations who participated in employer-supported training had similar characteristics to those who took formal or informal training (Tables 9.31 to 9.46).

In AETS, an employer is considered to have sponsored (or supported) a training activity if they have done any of a range of activities, including such things as providing the training, paying for the training (either directly or by reimbursing an employee), allowing the trainee to work a flexible schedule to accommodate training, or providing transportation to or from the training location.

In 2002, an estimated 319,000 adults from health occupations were involved in employer-supported training, representing slightly less than 40% of Canadians aged 25 to 64 in those occupations (Tables 9.31). This compares to only 20% for all occupations.

However, because participation in formal training overall is so high in health occupations (60% of Canadians aged 25 to 64 in those occupations), the proportion of participants who receive support from employers is actually lower than for all occupations. In fact, out of the 498,000 adults from health occupation involved in formal training in 2002, about 64% of them (319,000) received support from their employers. This compares to about seven in ten for all occupations (67%) (data not shown).

The main reason to participate in formal job-related training is to perform their job better

During 2002, about 78% of adults from health occupations reported participating in job-related training to perform their job better, slightly higher than for all occupations (72%) (Chart 9.7 and Table 9.10). About 20% of adults from health occupations also reported taking this type of training to start their own business or to change job. This compares to about a quarter (26%) for all occupations.

Chart 9.7

A large proportion of adults from health occupations reported participating in job-related training to perform their job better

Source: 2003 Adult Education and Training Survey, Statistics Canada.

In addition to reporting their training objectives, participants in job-related training were asked to indicate their training outcomes. Similar to what was observed for the training objectives, about 77% of adults from health occupations participating in formal job-related training reported performing their job better as their training outcome in 2002 (Table 9.11). On the other hand, while about 20% of adults from health occupations reported participating in formal job-related training to start their own business or to change job, about half this proportion (9%) reported this reason as being their training outcome. This may be attributable to the fact that while performing a job better would probably be the immediate effect of training, starting a new business or changing job would take more time.

While most courses taken by adults are supported by employers, few of the courses taken are actually required

During 2002, slightly less than 70% of the courses taken by adults from health occupations were supported by employers, not significantly different than what was observed for all occupations (Table 9.28). Payment of tuition fees, additional support from employers and training allowed during work hours were the most popular type of support provided by employers during that year (Table 9.29).

Of all courses taken by adults from health occupation during 2002, only a third was required by either an employer, a client, a professional association or a collective agreement (Table 9.28). The same was true for all occupations, where results were not significantly statistically different than what was observed for health occupations.

When courses are required, employers are the most likely to make the requirement

About two out of three required courses taken by adults from health occupations were required by an employer in 2002 (69%), not statistically significant different than what was observed for all occupations (75%) (Table 9.30).

During that same period, slightly less than 30% of the required courses taken by adults from health occupations were required by a professional association (Table 9.30). This is not surprising given the fact that some health professionals require to earn credits to maintain their registration, professional designation or membership.

A large proportion of required courses taken by adults from technical occupations related to dental health care such as denturists, dental hygienists, dental therapists, dental technicians and laboratory bench workers (97%), as well as physicians and dentists (81%) were required by a professional association (Table 9.30).

9.3 Unmet training needs or wants

Workers who participated in some training and who identified other training of interest to them demonstrate a commitment to on-going skill development and upgrading. Some adult workers—both participants and non participants—reported having unmet training needs or wants (Tables 9.47 to 9.52). This section examines the reasons participants and non-participants with unmet training needs/wants give for not taking the training, with a view to determining if these two groups face the same, or different, obstacles to training.

The 2003 AETS asked respondents about training that the respondent had wanted to take but didn't, and about training the respondents had needed to take but did not.

Having either the need or the desire to take job-related training can be considered as a proxy for being willing or ready to engage in a training activity. Because of this, and for analytical simplicity, the two groups (one with unmet needs and the other with unmet wants) are combined in this report.

Participants in job-related training from health occupations were more likely to report unmet training needs, but barriers to training are the same as for non-participants

Overall, about one-third (36%) of adults from health occupations reported that there was job-related training that they wanted or needed to take but did not in 2002 (data not shown). This proportion was considerably higher (26%) among workers who had participated in job-related training (Table 9.47), than it was for workers who did not participate in job-related training in 2002 (10%) (Table 9.48).

This suggests that even though training participants are already taking training, they may be unable to take additional training or the training of their choice.

Within health occupations, there were considerable similarities between training participants and non-participants in the reasons they gave for not taking training they wanted or needed (Tables 9.51 and 9.52). Among participants, the most often-reported reasons were: cost, a conflict between the training and work schedules, being too busy at work, and family responsibilities (Table 9.51).⁸ For non-participants, cost was also one of the most often reported reasons along with being too busy at work, family responsibilities and a conflict between the training and work schedules (Table 9.52).

Formal, job-related training includes courses or programs related to a worker's current or future job. These courses and programs have a structured plan whereby a student, led by a teacher or trainer, follows a planned program and receives some form of formal recognition upon completion, such as a certificate, diploma or degree.

4. Includes Veterinarians and Animal health technologists.

5. Includes Specialist physicians, General practitioners and Family physicians and Dentists.

6. Includes Specialist physicians and General practitioners and Family physicians.

Notes: Adults are defined as individuals aged 25 to 64.

Occupations are defined using the Standard Occupational Classification (SOC), 1991. See Appendix 2 for more details.

Formal, job-related training includes courses or programs related to a worker's current or future job. These courses and programs have a structured plan whereby a student, led by a teacher or trainer, follows a planned program and receives some form of formal recognition upon completion, such as a certificate, diploma or degree.

1. Excludes Veterinarians and Animal health technologists.

2. Not a Standard Occupational Classification (SOC) category.

3. Includes Managers in health care, Medical secretaries, Court recorders and medical transcriptionists, Inspectors in public and environmental health and occupational health and safety, Psychologists and Social workers.

4. Includes Veterinarians and Animal health technologists.

5. Includes Specialist physicians, General practitioners and Family physicians and Dentists.

6. Includes Specialist physicians and General practitioners and Family physicians.

Notes: Participants are defined as working adults aged 25 to 64 who participated in at least one job-related training activity during 2002.

Occupations are defined using the Standard Occupational Classification (SOC), 1991. See Appendix 2 for more details.

Formal, job-related training includes courses or programs related to a worker's current or future job. These courses and programs have a structured plan whereby a student, led by a teacher or trainer, follows a planned program and receives some form of formal recognition upon completion, such as a certificate, diploma or degree.

1. Excludes Veterinarians and Animal health technologists.

2. Not a Standard Occupational Classification (SOC) category.

3. Includes Managers in health care, Medical secretaries, Court recorders and medical transcriptionists, Inspectors in public and environmental health and occupational health and safety, Psychologists and Social workers.

4. Includes Veterinarians and Animal health technologists.

5. Includes Specialist physicians, General practitioners and Family physicians and Dentists.

6. Includes Specialist physicians and General practitioners and Family physicians.

Notes: Adult workers are defined as individuals aged 25 to 64 who were employed at some point during the reference year.

Occupations are defined using the Standard Occupational Classification (SOC), 1991. See Appendix 2 for more details.

Self-directed learning is training that involves little or no reliance on pre-determined guidelines for its organization, delivery or assessment, i.e. it does not lead to any formal qualification or certification. It must be undertaken by the participant with specific intention of developing job-related skills or knowledge.

Employer-supported formal job-related training includes courses or programs related to a worker's current or future job for which an employer have done any of a range of activities, including such things as providing the training, paying for the training (either directly or by reimbursing an employee), allowing the trainee to work a flexible schedule to accommodate training, or providing transportation to or from the training location. These courses and programs have a structured plan whereby a student, led by a teacher or trainer, follows a planned program and receives some form of formal recognition upon completion, such as a certificate, diploma or degree.

Occupations are defined using the Standard Occupational Classification (SOC), 1991. See Appendix 2 for more details.

Employer-supported formal job-related training includes courses or programs related to a worker's current or future job for which an employer have done any of a range of activities, including such things as providing the training, paying for the training (either directly or by reimbursing an employee), allowing the trainee to work a flexible schedule to accommodate training, or providing transportation to or from the training location.

These courses and programs have a structured plan whereby a student, led by a teacher or trainer, follows a planned program and receives some form of formal recognition upon completion, such as a certificate, diploma or degree.

1. Excludes Veterinarians and Animal health technologists.

2. Not a Standard Occupational Classification (SOC) category.

3. Includes Managers in health care, Medical secretaries, Court recorders and medical transcriptionists, Inspectors in public and environmental health and occupational health and safety, Psychologists and Social workers.

4. Includes Veterinarians and Animal health technologists.

5. Includes Specialist physicians, General practitioners and Family physicians and Dentists.

6. Includes Specialist physicians and General practitioners and Family physicians.

Notes: Participants are defined as working adults aged 25 to 64 who participated in at least one job-related training activity during 2002.

Occupations are defined using the Standard Occupational Classification (SOC), 1991. See Appendix 2 for more details.

Employer-supported formal job-related training includes courses or programs related to a worker's current or future job for which an employer have done any of a range of activities, including such things as providing the training, paying for the training (either directly or by reimbursing an employee), allowing the trainee to work a flexible schedule to accommodate training, or providing transportation to or from the training location.

These courses and programs have a structured plan whereby a student, led by a teacher or trainer, follows a planned program and receives some form of formal recognition upon completion, such as a certificate, diploma or degree.

10. Summary and concluding remarks

This publication presents some of what we currently know to begin to address some of the crucial questions facing Canadians today: Does Canada have enough interested individuals with the right skills who want to work in health? Does it have the infrastructure, capacity, and effective education system to ensure an adequate supply of health workers to meet future health care demands?

This study, an examination of current major Statistics Canada data sources related to the education of Canadians, has revealed some important information about what happens before, during and after health education. It focused on interest in health occupations, the characteristics of students and faculty in university health programs, the labour market experiences of recent graduates from these programs, as well as the ongoing participation of health workers in formal and informal training.

There is a great deal of interest in health occupations among youth pursuing high school study. Over 10% of 15-year-olds say they want to work in a health occupation and most of them have been interested in that job for at least a year. Moreover, many of these youth appear to have the necessary qualifications. They have higher than average reading, mathematics and science skills, and their grades reflect this.

By the time they complete high school, however, many youth change their minds and only half of those who wanted to work in health still do. But this is still a substantial number of youth and many of them appear highly qualified. Among 18- to 20-year-olds, youth who aspire to health occupations are more likely to have already gone on to postsecondary studies, many have already enrolled in health or health-related studies, and others may be pursuing pre-health science programs.

Another source of students in college and university health programs is immigrants. About 4% of immigrants in 2000 said they wanted to work in health-related occupations before immigrating to Canada. Many need additional education to practice in Canada and about one-third asked to have their existing foreign credentials assessed by an educational institution in the country. Most of these individuals already have a college or university education and over 70% obtained a full or partial recognition of their credentials.

Health programs seek to meet the needs of these youth and internationally-trained health workers, in addition to older Canadians who return to college or university to upgrade their credentials, pursue new health studies, or take courses as part of their ongoing training. There are multiple pathways into and through health studies. Students in health programs are more likely to have some previous postsecondary experience and/or full-time work experience. As a result, students enrolled in and graduating from health programs tend to be older than average.

Graduates from health programs are less likely to immediately pursue additional education. Instead, they tend to make quick transitions into the labour market. Within two years of graduating, over three-quarters of health graduates are employed in a health occupation, and some others, such as graduates from mental and social health services or public health programs work in related fields.

The labour market outcomes of health graduates show that there is a clear demand for their skills. Almost all health graduates (99%) who have not gone on to additional studies are employed two years after graduation, most of them in a full-time position. Moreover, even just two years after graduation, when some, particularly doctors, are still in residency or entry-level positions, they tend to earn more than graduates overall.

Higher likelihood of employment combined with higher earnings compensates for the fact that health graduates are more likely to have student debt and they tend to owe more. In spite of this, they are less likely to report difficulties repaying their loans, they are just as likely to have paid off their loans two years after graduation, and just as likely to expect to have their loans repaid within five years of graduating.

The final episode in this story of health education has to do with ongoing training of health workers. After entering the labour market, health workers continue to upgrade their skills, even when not required. Support for formal training is high among health employers and their workers take advantage of it. About 60% of adults in health occupations participated in formal job-related training in 2002, twice the rate observed for all occupations. The main reason for taking this training is to perform their job better. And while most courses are supported by employers, few of the courses taken are actually required by them. At the same time, however, about one-third of adults in health occupations reported unmet training needs, saying that there was training that they wanted or needed, but were unable to take.

Although we have good information on the individuals who are interested in health education and who ultimately pursue it and enter health occupations, further research is required to explore why youth lose interest in health education and what factors or barriers prevent qualified youth from pursuing health education. Moreover, there is very little information about health education programs themselves. What are the constraints to increasing capacity in postsecondary institutions, what factors or barriers influence the recruitment of students, effective training, retention of students in their programs or in health education overall, and positive labour market transitions after graduation? To what extent do financial and institutional constraints limit enrolment or affect student learning? What is the effect of the availability of clinical placements (training) on enrolment and learning? What factors limit the availability of clinical training? Why do so many health workers report unmet training needs?

In addition to questions related to the how many individuals complete health education, there are additional questions about who these individuals are. While visible minority students are overrepresented among the youth who want to work in health, they are underrepresented among those who graduate from health programs. Do they face different barriers that need to be addressed? Similarly, why are rural youth less interested in health occupations? What barriers do they

face? And who are the individuals who do decide to work in rural areas after they complete their programs? In particular, what do we know about health education for Aboriginal students who might be able to meet health care needs in Aboriginal communities? These are some of the questions that need to be addressed in ongoing research in order to fully understand the role that health education programs can play in improving the supply of health workers in Canada.

Appendix 1

Data sources used in this publication

This appendix contains an alphabetical listing of all data sources used in this publication.

Adult Education and Training Survey (AETS)

Centre for Education Statistics, Statistics Canada

Survey objectives:

The Adult Education and Training Survey (AETS) is Canada's most comprehensive source of data on individual participation in formal adult education and training. It is the only Canadian survey to collect detailed information about the skill development efforts of the entire adult Canadian population. While the content of the AETS has evolved over time, the central objectives of the 2003 survey remain the same as for previous surveys in this series. The main objectives are to:

- Measure the incidence and intensity of adults' participation in job-related formal training.
- Profile employer support to job-related formal training.
- Analyze aspects of job-related training activities such as: training provider, expenses, financial support, motivations, outcomes and difficulties experienced while training.
- Identify the barriers preventing individuals from participating in the job-related formal training they want or need to take.
- Identify reasons explaining adults' lack of participation and of interest in job-related formal training.
- Relate adults' current participation patterns to their past involvement in and plans about future participation in job-related training.
- Measure the incidence and frequency of adults' participation in job-related informal training.
- Examine the interactions between participation in formal and informal job-related training.

Target population:	The population is defined as people 25 years of age and over living in the ten provinces, excluding inmates of institutions such as prisons, hospitals, and long-term care facilities, residents of Indian reserves, and full-time members of the armed forces.
Survey frequency:	1984, 1986, 1990, 1992, 1994, 1998 and 2003.
Notes:	<p>Although data have been collected since 1984, the questionnaire structure and survey procedures were improved beginning in 1992. The 1994 AETS and the 1998 AETS were conducted based on the same methodology as the 1992 survey with only minor modifications to the questionnaire.</p> <p>In 2003, the content of the AETS was revised to take into account recommendations coming from consultation exercises. As a result, more than half of the survey that was conducted in 2003 was of new questions and the target population was modified. The 2003 survey focused on job-related training and education while the 1998 survey gathered information on all training and education activities. Respondents were then asked if the training or education had been related to a current or future job. These changes may affect the comparability of participation rates to some unknown extent. Consequently, the changes from 1998 to 2003 could be smaller than they appear.</p>

Longitudinal Survey of Immigrants to Canada (LSIC)

Special Surveys Division, Statistics Canada

Survey objectives:	<p>The Longitudinal Survey of Immigrants to Canada (LSIC), conducted jointly by Statistics Canada and Citizenship and Immigration Canada under the Policy Research Initiative, is a comprehensive survey designed to study the process by which new immigrants adapt to Canadian society.</p> <p>There exists a growing need for information on recent immigrants to Canada. As part of adapting to life in Canada, many immigrants face challenges such as finding suitable accommodation, learning or becoming more fluent in one or both of Canada's official languages, participating in the labour market or accessing education and training opportunities. The results of this survey will provide indicators of how immigrants are meeting these and other challenges. While integration may take many years, the LSIC is designed to examine the first four years of settlement, a time when newcomers establish economic, social</p>
---------------------------	--

and cultural ties to Canadian society. To this end, the objectives of the survey are two-fold: to study how new immigrants adjust to life in Canada over time; and, to provide information on the factors that can facilitate or hinder this adjustment.

Topics covered in the survey include language proficiency, housing, education, foreign credential recognition, employment, health, values and attitudes, the development and use of social networks, income, and perceptions of settlement in Canada.

Since immigration is a shared jurisdiction between national and provincial departments the information gathered through the LSIC will be beneficial to many groups including both federal and provincial government departments, immigrant settlement agencies, non-governmental organizations and researchers. Survey results will also play an important role in planning and developing programs that will assist future immigrants settling in Canada.

Target population:

The target population for the survey consists of immigrants who meet all of the following criteria:

- arrived in Canada between October 1, 2000 and September 30, 2001;
- were age 15 years or older at the time of landing;
- landed from abroad, must have applied through a Canadian Mission Abroad.

Individuals who applied and landed from within Canada are excluded from the survey. These people may have been in Canada for a considerable length of time before officially “landing” and would therefore likely demonstrate quite different integration characteristics to those recently arrived in Canada. Refugees claiming asylum from within Canada are also excluded from the scope of the survey.

Survey frequency:

Irregular:

- first wave taking place between April 2001 and May 2002; and
- second wave between December 2002 and December 2003.

National Graduates Survey (NGS)

Centre for Education Statistics, Statistics Canada

Survey objectives:

This survey was designed to determine such factors as: the extent to which graduates of postsecondary programs had been successful in obtaining

employment since graduation; the relationship between the graduates' programs of study and the employment subsequently obtained; the graduates' job and career satisfaction; the rates of under-employment and unemployment; the type of employment obtained related to career expectations and qualification requirements; and the influence of postsecondary education on occupational achievement.

Each graduating class is interviewed twice: two years after graduation (National Graduates Survey) and five years after graduation (Follow-up Survey of Graduates). The NGS is designed to measure the labour market outcomes of graduates from university, community college, and trade-vocational programs two and five years after graduation.

Target population:

Persons who completed the requirements for degrees, diplomas, or certificates from public universities, community colleges, and trade-vocational programs in Canada during the reference calendar year. Specifically, the types of graduates included are:

- graduates of university programs leading to bachelor's, master's, or doctorate degrees or specialized certificates or diplomas;
- graduates of postsecondary programs (of at least one year in duration and normally requiring secondary school completion or equivalent for admission) in Colleges of Applied Arts and Technology (CAAT), Collèges d'enseignement général et professionnel (CEGEP), community colleges, technical schools, or similar institutions;
- graduates of pre-employment programs (with a normal duration of at least three months) which lead to a certificate or diploma at the skilled trade level and are offered at trade-vocational schools, as well as many community colleges and technical institutes.

Excluded from the definition of graduates are:

- graduates from private postsecondary institutions such as computer training schools or commercial secretarial schools;
- individuals who completed continuing education courses, at universities and colleges, that do not lead to degrees or diplomas;
- individuals who completed part-time trade courses, such as adult education evening courses, while employed full time;
- individuals who completed vocational programs that were not in the skilled trades and/or were less than three months in duration;

- individuals in apprenticeship programs;
- graduates living outside of Canada and the United States at the time of the survey (starting from the 1995 cohort).

Survey frequency:

To date, four five graduating classes have been surveyed two and five years after graduation: 1982, 1986, 1990, 1995 and 2000. The graduating class of 2000 was surveyed for the first time, two years after graduation (in 2002). Data for the follow-up survey of the 2000 graduating class was not available at the time of this publication.

Programme for International Student Assessment (PISA)

Centre for Education Statistics, Statistics Canada

Survey objectives:

Programme for International Student Assessment (PISA) is an international assessment of the skills and knowledge of 15-year-olds which aims to assess whether students approaching the end of compulsory education have acquired the knowledge and skills that are essential for full participation in society. PISA is developed jointly by member countries of the Organisation for Economic Co-operation and Development (OECD).

The Programme for International Student Assessment (PISA) and the Youth in Transition Survey (YITS) is one project, which consists of two parallel survey programs:

- PISA is an international assessment of the skills and knowledge of 15-year-olds which aims to assess whether students approaching the end of compulsory education have acquired the knowledge and skills that are essential for full participation in society.
- YITS is designed to examine the patterns of, and influences on, major transitions in young people's lives, particularly with respect to education, training and work. Human Resources and Skills Development Canada and Statistics Canada have been developing the YITS in consultation with provincial and territorial ministries and departments of labour and education. Content includes measurement of major transitions in young people's lives including virtually all formal educational experiences and most about-market experiences, achievement, aspirations and expectations, and employment experiences. The implementation plan encompasses a longitudinal survey of each of two groups, ages 15 and 18-20, to be surveyed every two years.

- The 15-year-old respondents to the Reading Cohort (conducted in 2000) participated in both PISA and YITS. Starting in 2002, they will be followed up longitudinally by YITS.
- The 15-year-old respondents to the Mathematics Cohort (conducted in 2003) participated in both PISA and YITS. They will not be followed up longitudinally.

Target population:

The survey population was comprised of students who were 15 years of age and were attending any form of schooling in the ten provinces of Canada. Schools on Indian reserves were excluded, as were various types of schools for which it would be infeasible to administer the survey, such as home schooling and special needs schools. These exclusions represent less than 4% of 15-year-olds in Canada.

Survey frequency:

- PISA: Every three years (since 2000)
- YITS: Biennial (Cohorts of 2000)

Postsecondary Student Information System (PSIS)

Centre for education Statistics, Statistics Canada

Survey objectives:

The Postsecondary Student Information System (PSIS) (formerly known as the Enhanced Student Information System (ESIS)) is a national survey that enables Statistics Canada to provide detailed information on enrolments and graduates of Canadian postsecondary education institutions in order to meet policy and planning needs in the field of postsecondary education. Upon full implementation, PSIS will capture annually, enrolment and graduate information from all Canadian public postsecondary institutions.

PSIS collects information pertaining to the programs and courses offered at an institution, as well as information regarding the students themselves and the program(s) and courses in which they were registered, or from which they have graduated.

In addition, PSIS has been designed to provide longitudinal data. It has been designed to allow for the creation of a unique longitudinal record for each postsecondary student in Canada which will, in turn, provide a history of flows taken by a student as he/she progresses through the education system.

Target population:

The frame used is the list of Canadian public postsecondary institutions (universities, community colleges and trade and vocational training centres) compiled by the Centre for Education Statistics of

Statistics Canada. The collection unit is the Canadian postsecondary institutions. Each institution sends data pertaining to their programs and their students. PSIS population is a census of all students and graduates of all Canadian public postsecondary institutions.

Survey frequency: Annual.

Notes: PSIS replaces the University Student Information System, the Community College Student Information System and the Trade and Vocational Survey with a single survey offering common variables for all levels of postsecondary education. Historical enrolment and graduate data from the previous surveys have been converted using PSIS variable definitions and codesets to maintain the historical continuity of the statistical series.

University and College Academic Staff Survey (UCASS)

Centre for Education Statistics, Statistics Canada

Survey objectives: This database provides information on the number and characteristics of full-time teachers in degree-granting institutions.

Target population: Full-time teachers in degree-granting institutions.

Survey frequency: Annual (Academic year).

University Student Information System (USIS) – Enrolment and Graduations

Centre for Education Statistics, Statistics Canada

Survey objectives: The USIS database provides Canada-wide enrolment and graduate statistics from degree-granting universities and colleges. Data collected enables a general profile of students and the programs they take including sex, age, citizenship, geographic source of student, level of education, field of study, type of attendance (full-time, part-time), and year of graduation.

Target population: The target population for the enrolment statistics is all students enrolled in degree-granting institutions in Canada in programs leading toward a degree, diploma or certificate. This includes students enrolled in courses as well as students who have completed their course requirements and who are engaged in thesis writing or research. Those students who are taking courses eligible for credit but who are not seeking a degree, diploma or certificate (e.g., auditors)

are also included. The target population for the graduate statistics is all students who have received a degree, diploma, or certificate during the calendar year ending in December.

Survey frequency:

Annual. Enrolment data are available from the 1972/73 academic year to the present. Graduate data are from 1970 to the present.

Notes:

The Postsecondary Student Information System (PSIS), initially implemented in 2000, has begun to replace current postsecondary enrolment and graduate surveys, including the University Student Information System, with a single survey. While PSIS has been designed to continue the work of the postsecondary enrolment and graduation surveys, it will address their shortcomings and providing additional policy-relevant information.

Workplace and Employee Survey (WES)

Labour Statistics Division, Statistics Canada

Survey objectives:

The Workplace and Employee Survey (WES) is designed to explore a broad range of issues relating to employers and their employees. The survey aims to shed light on the relationships among competitiveness, innovation, technology use and human resource management on the employer side and technology use, training, job stability and earnings on the employee side.

The survey is unique in that employers and employees are linked at the micro data level; employees are selected from within sampled workplaces. Thus, information from both the supply and demand sides of the labour market is available to enrich studies on either side of the market.

The Workplace and Employee Survey offers potential users several unique innovations: chief among these is the link between events occurring in workplaces and the outcomes for workers. In addition, being longitudinal, it allows for a clearer understanding of changes over time.

There are two reference periods used for the WES. Questions concerning employment breakdown use the last pay period of March for the reference year while other questions refer to the last 12-month period ending in March of the reference year.

Target population:

The target population for the employer component is defined as all business locations operating in Canada that have paid employees in March, with the following exceptions:

- Employers in Yukon, Nunavut and the Northwest Territories; and
- Employers operating in crop production and animal production; fishing, hunting and trapping; private households, religious organizations and public administration.

The target population for the employee component is all employees working or on paid leave in March in the selected workplaces who receive a Canada Customs and Revenue Agency T-4 Supplementary form. If a person receives a T-4 slip from two different workplaces, then the person will be counted as two employees on the WES frame.

Survey frequency:

Annual:

- Since 1999 for employers (with birth annually); and
- For two years for employees (fresh samples every second survey occasion (first, third, fifth)).

Youth in Transition Survey (YITS)

Centre for education Statistics, Statistics Canada

Survey objectives:

The Youth in Transition Survey (YITS) is a longitudinal survey undertaken jointly by Statistics Canada and Human Resources and Skills Development Canada. This survey is designed to examine the major transitions in the lives of youth, particularly between education, training and work.

The Youth in Transition Survey is designed to examine the patterns of, and influences on, major transitions in young people's lives, particularly with respect to education, training and work. Content includes measurement of major transitions in young people's lives including virtually all formal educational experiences and most about-market experiences, achievement, aspirations and expectations, and employment experiences. The implementation plan encompasses a longitudinal survey of each of two cohorts, ages 15 and 18-20, to be surveyed every two years (Cycle 1 was implemented in 2000 and Cycle 2 in 2002).

Target population:

- The survey population for the 18- to 20-year-old cohort includes persons born in the years 1979 to 1981. Geographically, the target population excludes the northern territories, Indian reserves, Canadian Forces bases and some remote areas.
- The survey population for the Reading Cohort (15-year-olds) comprises persons who were born in 1984 and were attending any form of schooling in the ten provinces of Canada. Schools on Indian reserves were excluded, as were various types of schools for which it would be infeasible to administer the survey, such as home schooling and special needs schools. These exclusions represent less than 4% of 15-year-olds in Canada.

Survey frequency:

Biennial since 2000.

Appendix 2

Occupational classifications

Occupations are classified according to standard classifications (1991 Standard Occupational Classification (SOC 1991) or 2001 National Occupational Classification – Statistics (NOC-S 2001)) depending on the data source. As such, health and health-related occupations include, but are not limited to, practitioners of health care.

The following tables outline the specifications used for the analysis of health and health-related occupations using both SOC 1991 and NOC-S 2001.

Appendix table 2.1

Classification of health and health-related occupations using SOC 1991

Occupations	SOC 1991

Appendix 3

Classification of Instructional Programs

The current classification used at Statistics Canada to classify instructional programs according to field of study is the Classification of Instructional Programs (CIP), Canada, 2000.

The following table outlines the specifications used for the analysis of health and health-related education programs in this report. Note: In Section 5, with the exception of Physical therapy / therapist (CIP = 51.2308) and Occupational therapy / therapist (CIP = 51.2306), type of program is defined using the 2- or 4-digit level of the CIP. Where categories are grouped CIP codes, the specifications for both Section 5 and Sections 6 and 7 are outlined.

Appendix table 3.1

Classification of health and health-related education programs using CIP 2000

Program	CIP 2000
All programs	All CIP
Health programs ¹	In Sections 6 and 7: All CIP starting with 51 and with 60, except 51.1104, 51.0808 and those starting with 51.24, 51.25 and 60.03; In Section 5: All CIP starting with 51 and with 60, except those starting with 51.24, 51.25 and 60.03.
Health services / allied health / health sciences, general	51.00
Chiropractic	51.01
Communication disorders sciences and services	51.02
Communication disorders, general	51.0201
Audiology / audiologist and hearing sciences	51.0202
Speech-language pathology / pathologist	51.0203
Audiology / audiologist and speech-language pathology / pathologist	51.0204
Communication disorders sciences and services, other	51.0299
Dentistry	51.04

Physicians ⁶	In Sections 6 and 7: CIP starting with 51.12 and 60.02; found under "Health programs" in Section 5.
Medical radiation technologists ⁶	In Sections 6 and 7: CIP=51.0905 or CIP=51.0907 or CIP=51.0911; no equivalent in Section 5.
Medical laboratory technologists ⁶	In Sections 6 and 7: CIP=51.1002, CIP=51.1004, CIP=51.1005, CIP=51.1010 and CIP=51.0802; no equivalent in Section 5.

1. In Sections 6 and 7, excludes veterinary programs at the 4- and 6-digit CIP level. In Section 5, excludes veterinary programs at the 4-digit level.
2. In Sections 6 and 7, excludes Veterinary / animal health technology / technician and Veterinary assistant. No exclusions in Section 5.
3. In Sections 6 and 7, excludes Pre-veterinary studies. No exclusions in Section 5.
4. In Sections 6 and 7, includes veterinary programs but excludes all health programs, Psychology, Social work, Epidemiology and Health and physical education / fitness. In Section 5, includes veterinary programs but excludes all health programs, Psychology, Social work and Health and physical education / fitness.
5. In Sections 6 and 7, these health programs are special groupings from health programs above. In the case of Medical laboratory technologists, they are predominantly from Clinical / medical laboratory science and allied professions, with the exception of Clinical / medical laboratory assistant, which comes from Allied health and medical assisting services. These health programs were selected as they represent the priority occupations as determined from the health human resources and education consultations conducted in 2005 (see Allen et. al. 2006). There is no equivalent in Section 5.
6. Not a standard Classification of Instructional Programs (CIP) category.

For a detailed description of the above programs, visit www.statcan.ca. Click on **English** button, click on **Definitions, Data source and methods** link in the left navigation panel and then, click on **Instructional Programs** link under the Standard classifications category. Click on **CIP Canada 2000** link under Classifications, click on **Classification** and then, click on either **51. Health Professions and Related Clinical Sciences** under Chapter I – Academic and Occupationally-Specific Programs or **60. Dental, Medical and Veterinary Residency Programs** under Chapter II – Dental, Medical and Veterinary Residency Programs.

Appendix 4

Classification of principal subject taught

The following table outlines the specifications used for the classification of principal subject taught in this report.

Appendix table 4.1

Classification of principal subject taught in the health field

Category	Course name
Dentistry	Dentistry (Professional program) Dental specialties
Medical sciences	Medicine (Professional program) Anatomy Biochemistry Biophysics Embryology Endocrinology Genetics Histology Neurophysiology Pharmacology Physiology Other basic sciences
Medical and surgical specialties	Medical specialties Surgical specialties
Paraclinical sciences	Immunology Microbiology Pathology Other paraclinical sciences
Nursing	Nursing
Optometry	Optometry
Pharmacy	Pharmacy
Epidemiology and public health	Epidemiology and public health
Occupational therapy	Occupational therapy
Rehabilitation	Aural and oral rehabilitation Other rehabilitation
Physical therapy	Physical therapy
Health administration	Health administration
Psychology	Psychology
Clinical / medical laboratory science and allied professions	Medical technology
All other health subjects	Other health professions and occupations Health professions, n.e.s.

For a detailed description of the above principal subject taught, visit www.statcan.ca. Click on **English** button, click on **Definitions, Data source and methods** link in the left navigation panel, click on **Alphabetical list** link under the Surveys and statistical programs category and then, click on **3161: University and College Academic Staff System – Part-time Staff** link. Click on **Additional documentation** link under Data sources category, click on **Part-time University Teaching Staff: Data Element Manual (in PDF format)** link and then, refer to **Element No. 13 – Principal Subject Taught** from pages 28 to 50.

Appendix 5

North American Industrial Classification System

The classification system that Statistics Canada uses to organize economic data by industry is the North American Industry Classification System (NAICS). NAICS was first developed in 1997 by the three trading partners under the North American Free Trade Agreement (NAFTA) in order to provide a common statistical framework that will facilitate analysis of the three economies. It was updated in 2002. The next update is planned for 2007.

Definition of industry

An **industry** is a group of production entities that use similar production processes to create goods and services. These entities may take the form of corporations, mines, factories, unincorporated businesses, etc. Certain legal entities, such as multinational corporations, may produce such a vast range of different products that they are not useful for defining industries for the purpose of preparing production statistics. Nevertheless, most complex organizations are of small internal units, generally located in a single place, with relatively homogeneous output and relatively similar production processes and technology. These units may form the basis of a classification system.

The establishment has this function in enterprise statistics. While establishments may engage in a variety of activities, these are generally of limited scope, and a single activity tends to dominate. The activity associated with the highest value-added (that is, the value of the outputs minus the cost of the inputs) is considered as the establishment's "principal activity," and the establishment is classified to an industry corresponding to this principal activity.

It should be noted that the group of establishments that constitute an industry may vary over the years, owing to the creation of new establishments, the closure of establishments or simply a change in production processes. Statistics Canada periodically examines the classification of establishments to industries. A given industry may produce goods that are not considered its principal product. This is a secondary activity. By the same token, some of the main products of this industry may also be manufactured by other industries.

As defined by NAICS 2002, the Educational Services sector comprises establishments primarily engaged in providing instruction and training in a wide variety of subjects. This instruction and training is provided by specialized establishments, such as schools, colleges, universities and training centres. These establishments may be privately owned and operated, either for profit or not, or they may be publicly owned and operated.

The structure of NAICS takes the form of a hierarchical list of all economic activities in the country. The numbering system adopted by NAICS includes five levels and uses six-digit numerical coding. The first two digits designate the sector, the third digit designates the sub-sector, the fourth designates the group and the fifth designates the class. The sixth digit is used to designate national classes specific to each country. NAICS 2002 covers economic activities in 20 sectors and 928 Canadian industries.

The following is an abridged version of the Health care and social assistance sector in NAICS.

Appendix table 5.1

Classification of the Health Care and Social Assistance sector using NAICS 2002

Industry	NAICS 2002
Health Care and Social Assistance	62
Ambulatory Health Care Services	621
Offices of Physicians	6211
Offices of Physicians	62111
Offices of Physicians	621110
Offices of Dentists	6212
Offices of Dentists	62121
Offices of Dentists	621210
Offices of Other Health Practitioners	6213
Offices of Chiropractors	62131
Offices of Chiropractors	621310
Offices of Optometrists	62132
Offices of Optometrists	621320
Offices of Mental Health Practitioners (except Physicians)	62133
Offices of Mental Health Practitioners (except Physicians)	621330
Offices of Physical, Occupational, and Speech Therapists and Audiologists	62134
Offices of Physical, Occupational, and Speech Therapists and Audiologists	621340
Offices of All Other Health Practitioners	62139
Offices of All Other Health Practitioners	621390
Out-Patient Care Centres	6214
Family Planning Centres	62141
Family Planning Centres	621410
Out-Patient Mental Health and Substance Abuse Centres	62142
Out-Patient Mental Health and Substance Abuse Centres	621420
Other Out-Patient Care Centres	62149
Community Health Centres	621494
All Other Out-Patient Care Centres	621499
Medical and Diagnostic Laboratories	6215
Medical and Diagnostic Laboratories	62151
Medical and Diagnostic Laboratories	621510
Home Health Care Services	6216
Home Health Care Services	62161
Home Health Care Services	621610
Other Ambulatory Health Care Services	6219
Ambulance Services	62191
Ambulance (except Air Ambulance) Services	621911
Air Ambulance Services	621912
All Other Ambulatory Health Care Services	62199
All Other Ambulatory Health Care Services	621990
Hospitals	622
General Medical and Surgical Hospitals	6221
General Medical and Surgical Hospitals	62211
General (except Paediatric) Hospitals	622111
Paediatric Hospitals	622112
Psychiatric and Substance Abuse Hospitals	6222
Psychiatric and Substance Abuse Hospitals	62221
Psychiatric and Substance Abuse Hospitals	622210
Specialty (except Psychiatric and Substance Abuse) Hospitals	6223
Specialty (except Psychiatric and Substance Abuse) Hospitals	62231
Specialty (except Psychiatric and Substance Abuse) Hospitals	622310

Appendix table 5.1 (concluded)**Classification of the Health Care and Social Assistance sector using NAICS 2002**

Industry	NAICS 2002
Nursing and Residential Care Facilities	623
Nursing Care Facilities	6231
Nursing Care Facilities	62311
Nursing Care Facilities	623110
Residential Developmental Handicap, Mental Health and Substance Abuse Facilities	6232
Residential Developmental Handicap Facilities	62321
Residential Developmental Handicap Facilities	623210
Residential Mental Health and Substance Abuse Facilities	62322
Residential Substance Abuse Facilities	623221

Click on **NAICS 2002** link under Classifications, click on **Standard Classification**, then click on **62 – Health Care and Social Assistance** link.

Appendix 6

A focus on nursing

Enrolment information from the University Student Information System (USIS) and the Postsecondary Student Information System (PSIS) provided in this report are limited to the public university sector. It does not include data on continuing education programs, college data, nor does it reflect the situation in private postsecondary institutions (see section 5.1 for further information). As such, it does not reflect the entirety, complexity, or variety of education and training available to each of the health occupations. In other words, there are individuals in health programs from colleges and private postsecondary institutions that are not reflected in this report. The implications of these limitations in relation to the nursing education and training system are discussed in this appendix.

The lack of availability of college enrolment and graduate data from the PSIS data collections has particular consequences for the picture of the volume and nature of activity in nursing programs in Canada. The Canadian Nurses Association adopted a policy of baccalaureate education for new Registered Nurses in 1982, and since then provinces and territories are in the process of converting to these programs, with many schools phasing out diploma programs or introducing collaborative baccalaureate programs. During this process, a number of college diploma programs still exist across the country. Hence, the publication of enrolment data solely at the university level does not reflect the entire scope of nursing education and training in the postsecondary system. The lack of availability of college data is particularly important for Quebec and Manitoba, where a significant number of diploma programs for Registered Nurses are offered.⁹ Although diploma programs for Registered Nurses at the college level are being phased out in Ontario, Alberta, British Columbia and the Northwest Territories, these jurisdictions will have registered nurse graduates from the college system for a number of years yet.

In some jurisdictions, the college system will continue to play a role in the education and training of nurses through the establishment of collaborative degree programs—which have turned out to be the mechanism adopted to convert from diploma to degree programs. Collaborative refers to a relationship of cooperation for program delivery between a university and one or more college-level institutions.¹⁰ Depending on the data reporting arrangements between the college and university partners offering collaborative programs, information for those years that a student takes the program at the college may or may not be reflected in the university enrolment counts presented in this report. Although not yet confirmed, there is a possibility that college data may be available in 2009 from the PSIS database.

Another considerable limitation of the statistics presented in this report concerning nursing enrolment and graduates at the bachelor's and other undergraduate degrees level is that they do not distinguish between entry-to-practice and post-registered nurse (post-RN) programs. Post RN-programs are designed to lead to the achievement of a baccalaureate degree for those persons who already hold a registered nurse (RN) designation, but not a prior baccalaureate in nursing, and who wish to upgrade their academic qualifications to the baccalaureate level. It is important to work towards being able to capture this distinction in the data as the supply of graduates from post-RN programs do not represent new additions to the nursing labour supply. Furthermore, the data presented in this report do not capture other types of continuing education programs in the form of certificate programs that provide specialized training which adds to the competencies of a nurse in a specific area, for example, oncology, pediatric nursing, etc.

Finally, the category "Nursing" encompasses nurse practitioner programs and registered psychiatric nursing programs along with other categories of nurses. Nursing data in this report therefore does not differentiate between those studying to become registered nurses from those in other types of nursing programs or specialties.

Appendix 7

A distinction between “enterprise,” “company,” “establishment” and “location”

The **enterprise** is an independent unit for which a complete set of financial statements is available. The enterprise directs and controls the allocation of resources relating to its operations, and for which consolidated financial and balance sheet accounts are maintained. In the case of most small- and medium-sized businesses, the enterprise and the establishment are identical. Large and complex enterprises, however, consist of more than one establishment, which may belong to different industries under NAICS.

The **company** is the level at which operating profit can be measured, for which income and expenditure accounts and balance sheet information are maintained from which operating profit and the rate of return on capital can be derived. An enterprise may include one or more companies.

The **establishment** is the level at which the accounting data required to measure production are available. The establishment is the most homogeneous unit of production for which the business maintains accounting records from which it is possible to assemble data on the gross value of production and labour and capital used in production.

At the lowest level of a firm’s operating structure are production units, such as plants, factories, farms, mines, warehouses, stores, airports or movie theatres. The **location** (or workplace) is a producing unit at a single geographical location where economic activity is conducted and for which, at a minimum, employment data are available.

Appendix 8

Health Human Resources and Education conceptual framework

The **Health Human Resources and Education conceptual framework** is designed to show the general relationships between the education system and the health labour market, showing the generic flows of individuals through educational institutions and into the health labour market. Many detailed flows and activities are not specified here, but are assumed within the framework. This is particularly true of the multiple pathways in and out of postsecondary education.

Each box represents generic institutions or institutional processes: postsecondary health education, recognition (and assessment), licensure or registration and the health labour market. These are intended conceptually. For example, within the postsecondary education box are conceptually all Canadian postsecondary institutions providing health-related education. The movement of individuals between educational institutions, between programs—whether bridging, access, collaborative, direct-entry or graduate studies—occurs within this box.

The flows between boxes (indicated with a triangle) describe generic movements rather than specific pathways. In general, therefore, the framework outlines the route from aspiring to a health career, to training, graduation, entry into the labour market, and possible reintegration back into educational institutions as a student, educator or researcher.

In order to measure the main flow of individuals through education and into the health labour market, it is important to identify how all of these flows (and the leakages implied by some of them) influence the supply of new entrants into health occupations.

Endnotes

1. For example, as recently as 1992-93, women accounted for only 41% of enrolment in dentistry programs at the bachelor's and other undergraduate degree levels (Postsecondary Student Information System).
2. This report has not analyzed medical and dental residency programs as there is a need to review how these programs are being classified according to level of study.
3. Entry-to-practice here refers to programs that provide the qualification for graduates to qualify for initial licensure in nursing.
4. For the purpose of this report, "designated groups" refer to members of a visible minority, Aboriginal peoples and persons with disabilities.
5. (1) Health services / Allied health / Health sciences, general, (2) Allied health diagnostic, intervention and treatment professions (3) Public health (4) Clinical / medical laboratory assistant (5) Psychiatric / mental health nurse / nursing (6) Licensed practical / vocational nurse training.
6. Workplaces who introduced new products, services or processes or improved them between April 1st, 2002 and March 31st, 2003.
7. Locations in the Yukon, Nunavut and the Northwest Territories were excluded, along with locations in the agriculture, fishing, and road, bridge and highway maintenance fields and public administration.
8. Proportions do not add to 100% as many respondents reported more than one reason.
9. The account of transitions in policies and programs for Nursing in Canada is culled from "The National Student and Faculty Survey of Canadian Schools of Nursing 2004-2005: Survey Methodology" access on the Web site of the Canadian Nurses Association on October 2, 2006 and email communication with the Canadian Nurses Association (Lisa Little email of August 30 2006 to Robert Shearer, Health Canada).
10. The National Students and Faculty Survey of Canadian Schools of Nursing 2004-2005: Survey Methodology states: "The extent and type of collaboration existing between a university and its collaborating partner or partners varies greatly. At one extreme, the university may be responsible only for ensuring that the curriculum meets university degree standards, and the college may deliver the entire curriculum on its sites. At the other extreme, the university may be heavily involved not only in approving academic standards, but also in delivering sizable amounts of the curriculum on its campuses.

Culture, Tourism and the Centre for Education Statistics Research Papers Cumulative index

Statistics Canada's **Division of Culture, Tourism and the Centre for Education Statistics** develops surveys, provides statistics and conducts research and analysis relevant to current issues in its three areas of responsibility.

The **Culture Statistics Program** creates and disseminates timely and comprehensive information on the culture sector in Canada. The program manages a dozen regular census surveys and databanks to produce data that support policy decision and program management requirements. Issues include the economic impact of culture, the consumption of culture goods and services, government, personal and corporate spending on culture, the culture labour market, and international trade of culture goods and services. Analysis is also published in *Focus on Culture* (87-004-XIE, free, <http://www.statcan.ca/bsolc/english/bsolc?catno=87-004-X>).

The **Tourism Statistics Program** provides information on domestic and international tourism. The program covers the Canadian Travel Survey and the International Travel Survey. Together, these surveys shed light on the volume and characteristics of trips and travellers to, from and within Canada.

The **Centre for Education Statistics** develops and delivers a comprehensive program of pan-Canadian education statistics and analysis in order to support policy decisions and program management, and to ensure that accurate and relevant information concerning education is available to the Canadian public and to other educational stakeholders. The Centre conducts fifteen institutional and over ten household education surveys. Analysis is also published in *Education Matters* (81-004-XIE, free, <http://www.statcan.ca/bsolc/english/bsolc?catno=81-004-X>), and in the *Analytical Studies Branch research paper series* (11F0019MIE, free, <http://www.statcan.ca/bsolc/english/bsolc?catno=11F0019M>).
