The articles contained in ***Feedback*** are derived from *Service Difficulty Reports* (SDRs) submitted by Aircraft Maintenance Engineers (AMEs), owners, operators and other sources in accordance with *Civil Aviation Regulation* (CAR) 521.

SDRs are normally published verbatim. Transport Canada assumes no responsibility for the accuracy or content of any of these reports. Only spelling errors are corrected and content may be reduced as well as personal references deleted.

All defects or occurrences should be reported to Transport Canada through the Service Difficulty Reporting Program. For additional information about this program or concerning an article in ***Feedback*** magazine, contact your nearest Transport Canada Centre.

***Feedback** est aussi disponible en français.*

DHC 8 100/200/300 Series
Passenger Seatbelt – Correct Orientation of Hook End

The purpose of this Article is to inform operators of problems regarding the incorrect installation of the hook end of the aisle passenger seats.

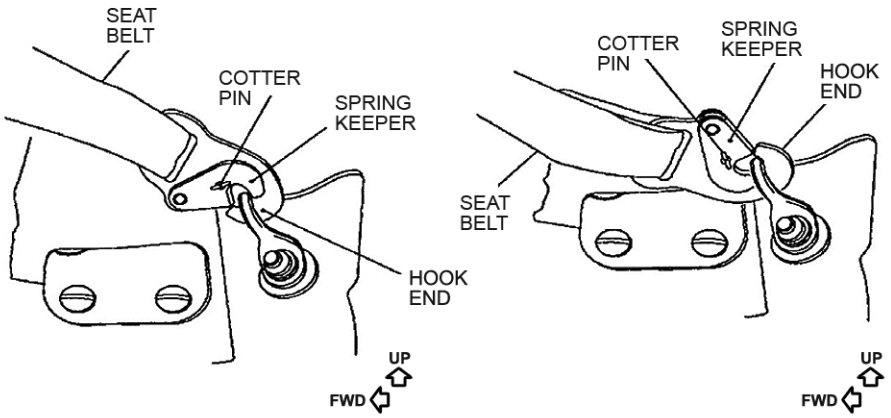
A recent event occurred during severe turbulence whereby several passengers received injuries as a result of being ejected from their aisle seats. The cause was due to incorrect positioning of the seat belt hook ends. Shortly thereafter, another separate and similar event occurred, again resulting in passenger injuries.

Investigation determined that the released seatbelts had been incorrectly installed with the hook end of the seatbelt in the downwards-facing position ("spring keeper" facing downwards). The seatbelts had flipped around on the U shaped attachment fitting and become lodged under a plastic trim molding on the aisle side of the passenger seat. This caused the "spring keeper" to bend to the side, thus allowing the respective aisle seatbelt to become disengaged.

Bombardier Aerospace has taken corrective action and issued Service Bulletin 8-25-349, Revision C, dated January 18, 2008.

Transport Canada Comments:

Transport Canada highly recommends that operators and owners comply with the above SB 8-25-349, Rev C, which provides instructions to inspect the aisle seatbelts to ensure that the seat belt hook end is in the "up" position (i.e. spring keeper facing up) 🛠



BEECH 200 SDR # 20090106004

Cabin Door Hooks - Security

SDR submitted:

During cruise flight, the crew noted that the maximum cabin differential pressure could not be reached. Following landing at the planned airfield, the maintenance crew conducted ground tests and then discovered that both the upper cabin door hooks were turned sideways, thus preventing positive latching of the door. It was apparent that the cabin air leakage was because the door latching mechanism was not positively engaged.

There was no record of any recent maintenance being done on the door prior to this event.

Transport Canada Comments:

To date there have been over 50 occurrences on the Beechcraft King Air and Beech 99 aircraft where the cabin airstair door has come open during flight. In some cases, the door has completely separated from the aircraft.

It is recommended that AMEs be particularly attentive to the maintenance instructions for proper door rigging/adjustments and lubrication. Additionally, a close visual inspection to check for wear and corrosion is required for the various parts of the door.

Flight crewmembers are required to perform several checks to ensure the door is closed and locked prior to flight. Cabin door security shall be verified before takeoff by attempting to rotate the door handle counterclockwise without depressing the release button.

This will confirm that the cabin door lock mechanism is positively engaged.

Presently, there are two FAA Airworthiness Directives (ADs), AD 76-10-10 and AD 77-18-04 addressing longstanding issues related to the security of the cabin door. Beechcraft has also published several maintenance instructions regarding care of the cabin door.

The FAA has informed TCCA that no additional corrective action is planned at this time. 🛠

Cracked Windshield

SDR submitted:

Approximately ten minutes after leveling off at 17 000 feet the crew noted that the first officer side windshield had several small cracks in the top right corner as well as one larger crack that looked similar to when a rock hits a car windshield.

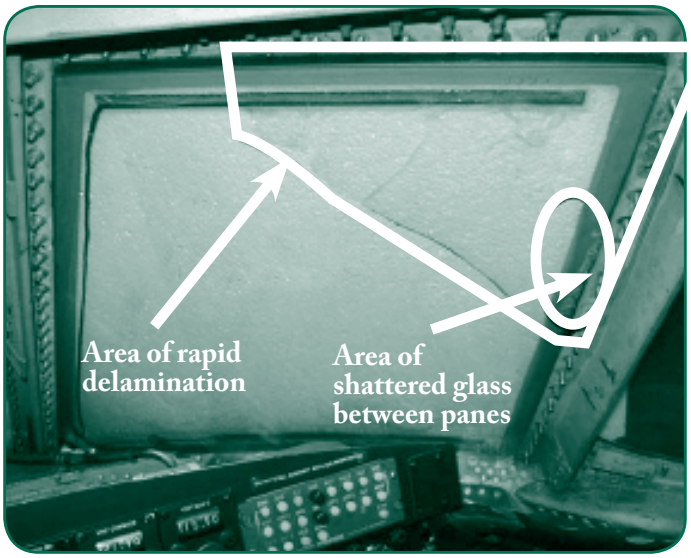
They could also see small fragments of glass sliding down in between what appeared to be two panes of glass. The crew was not sure at what point during the flight the problems started to occur, but there were no problems earlier in the morning.

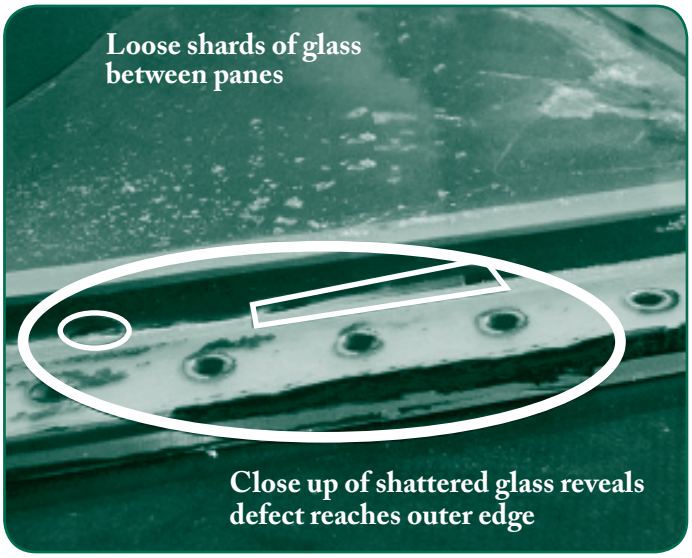
Maintenance examined the windshield and found major delamination and cracks on the window. In various areas around the window the inner pane was beginning to separate from the outer pane and over time might have fallen inward.

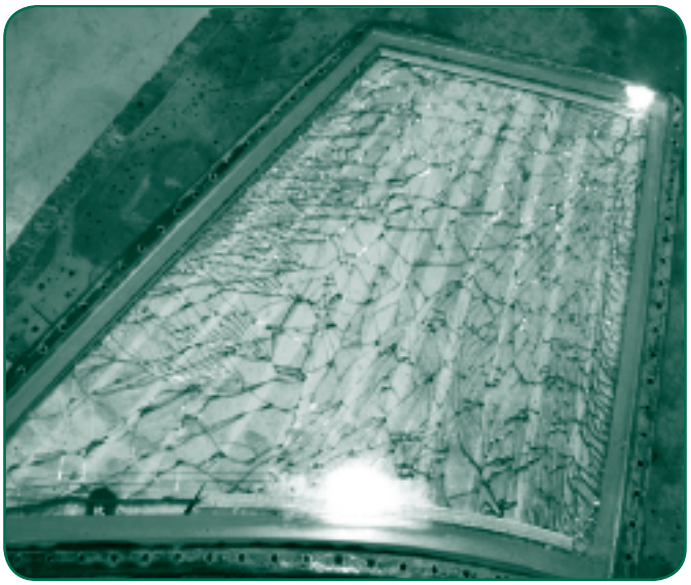
Maintenance replaced the windshield and returned the aircraft to service.

Transport Canada Comments:

The operator previously had a similar defect on the same part number windshield. The windshields were sent to the manufacturer for investigation and determination of failure cause. 🛠







CESSNA 560 SDR # 20090325011

Flight Compartment Side Window – 7" Crack

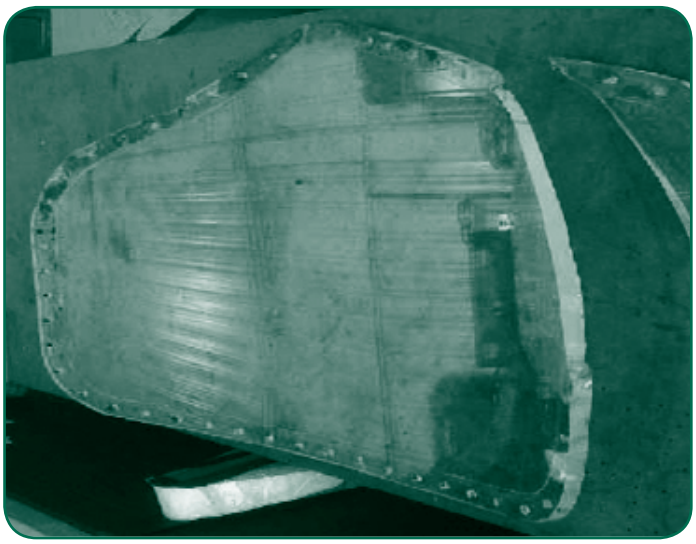
SDR submitted:

At flight level 370, the cockpit L/H side window outer pane cracked. The 7" crack was located on the forward lower corner. The aircraft returned to base without incident.

Upon removal of the subject window, significant corrosion was found in several of the fasteners. It was also noted that the window had developed smaller cracks emanating from other screw holes.

The operator's maintenance program inspects the cockpit side window using a prism method every 300 hours or 12 months. The last inspection was completed 171 hours ago.

Prior to operation by the new owner, the aircraft had been repaired due to an impact with a flock of birds in this same general area. The aircraft was parked outside for 3 months awaiting repairs and it is believed that rain/moisture may have migrated into this area and promoted corrosion around the fasteners.



Transport Canada Comments:

Follow up investigation with the FAA and Cessna revealed other similar failures. Cessna stated that there have been no previous defect reports related to corrosion around the L/H or R/H side windows. The prism inspection is designed to find small cracks in the window originating from the fastener holes. It is not designed to detect corrosion. Cessna will continue to monitor any future Service Difficulty Reports (SDR) defect reports. It is recommended that maintainers and operators continue to closely examine windshields, cockpit side windows and cabin windows for evidence of cracks, scratches, discoloration, crazing and other deformations. Please note that Cessna Aircraft had previously issued Service Bulletin (SB) 560-56-01 on this subject matter. 🛠

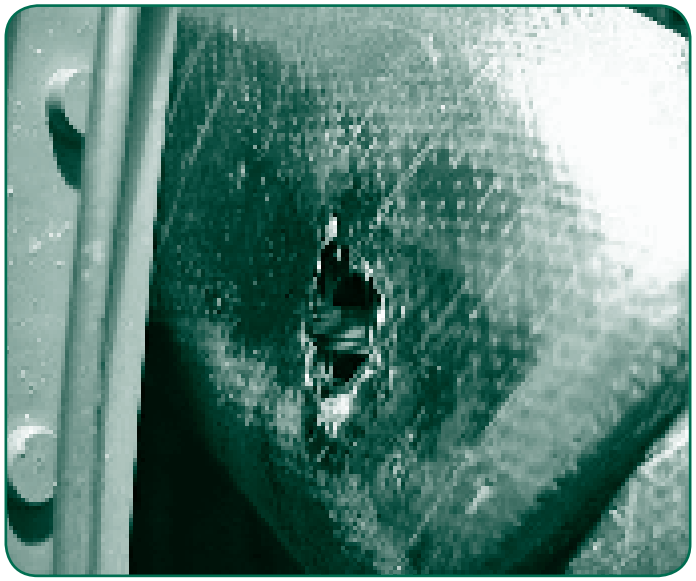
LEARJET, 45 SDR # SDR 20090414004

Anti Ice Leak

SDR submitted:

Pilot reported a "wing/stab leak" master caution message. Investigation of the problem revealed that the left hand horizontal stab anti ice flexible duct (located at the vertical stab to horizontal stab junction) was cracked.

The duct chafing on the structure, underneath the vertical stabilizer bullet fairing, probably caused the crack. Clearance between the flexible ducts and the structure is minimal in this area. Velcro straps that tie the L/H and R/H flexible ducts were no longer installed and were found lying in the bottom of the access panel.



Transport Canada Comments:

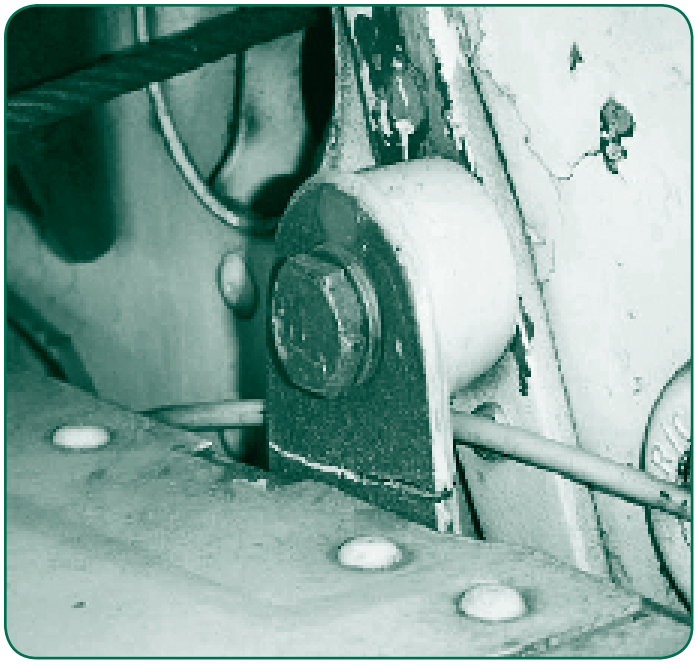
Keep this in mind when performing inspections in this area. 🛠

CESSNA 207A SDR # 20090522003

Horizontal Stabilizer – Cracked Front Attachment Fitting

SDR submitted:

While carrying out a routine inspection in the immediate area, excessive play was noted while manually moving the horizontal stabilizer. While inspecting more closely, the AME noticed that the R/H forward horizontal stabilizer bracket was cracked all the way through. The crack was located just below the bolt hole.



Transport Canada Comments:

TCCA has reported this event to both the FAA and the Type Certificate Holder. Additionally, the SDR database revealed numerous defect reports related to the front stabilizer attachment fitting P/N 1232013-1.

In order to improve the service life of these fittings, TCCA recommends that operators comply with Service Bulletin (SB) 88-3 and Cessna Service Kit (SK) 207-8. Incorporation of the aforementioned SB and SK is highly recommended if loose rivets or cracks in the stabilizer attach bulkhead, cracked doublers or fittings are discovered in the immediate area. 🛠

BOMBARDIER, CL600 2B19 (RJ100) SDR # 20090521004

APU - Chafed Fuel Line

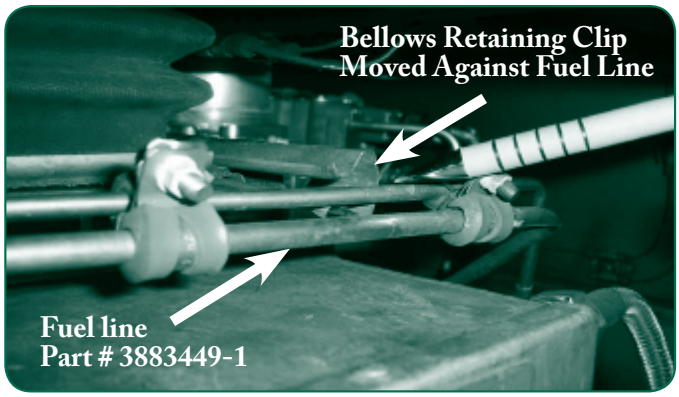
SDR submitted:

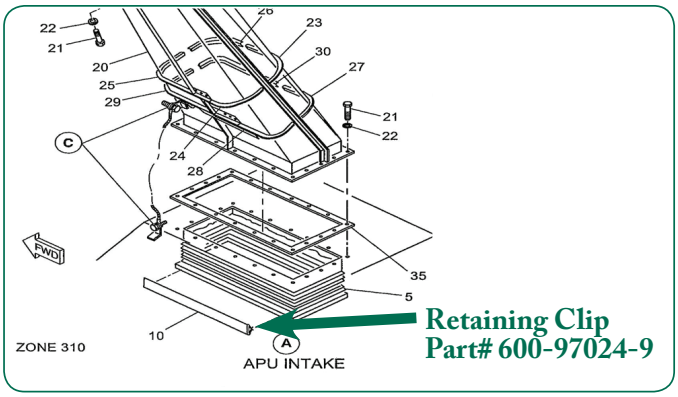
Crew reported that they had an oil smell from the APU when air conditioning system was selected. It was discovered that the APU fuel line Part Number (P/N) 3883449-1(FCU to nozzles) was found chafed thru due to the migration of the APU inlet bellows retaining clip P/N 600-97024-9 (ref CRJ 200 IPC 49-14-00 Fig 1 Item 10).

The SDR submitter states that this type of defect could potentially occur again due to the fact that the retaining clip is not secured (not clamped), allowing it to vibrate around. The APU fuel line is situated directly aft of the clip with a separation of approximately one inch.

Transport Canada Comments:

Transport Canada recommends close examination of these components at the next APU air inlet assembly inspection. Always ensure that fuel and oil lines are properly clamped and are adequately separated to prevent rubbing and chafing. The submitter is currently inspecting these at intervals of 2 000 airframe hours and 300 APU hours. 🛠





CANADAIR, CL215 6B11(CL415) SDR # 20090505004

Damaged Wires

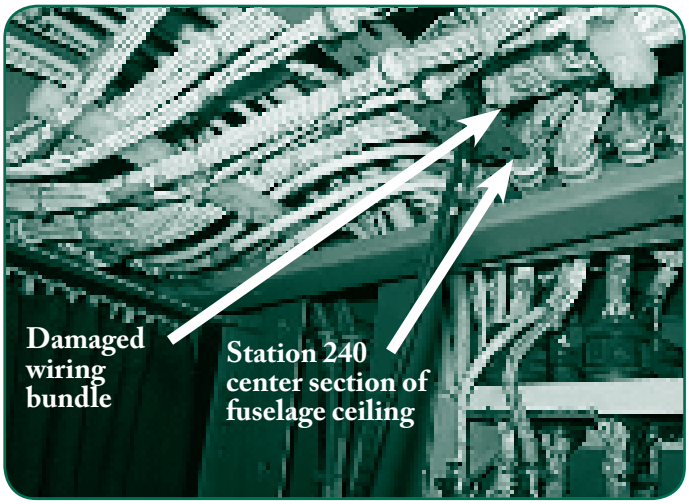
SDR submitted:

While troubleshooting the R/H engine tail pipe overheat system "failed to test" problem which was found during the preflight check; the avionic technician found 7 to 8 wires in an unrelated wiring bundle chafed and damaged. These electrical wires are located at fuselage station 240 in the ceiling of the aircraft. It is noted that these wires had nothing to do with the issue that was found during the preflight check. All other systems were functioning correctly.

The wire bundle has not been replaced since its original installation.

Transport Canada Comments:

Good find by the Avionic Technician. In this case, being diligent paid off. Good work. Always ensure electrical wires are adequately secured and separated from adjacent structure to prevent rubbing and chafing which may lead to possible system malfunctions. 🛠



DHC 8 314 SDR # 20090616010

R/H Aileron Hinge Bearing – Migration

SDR submitted:

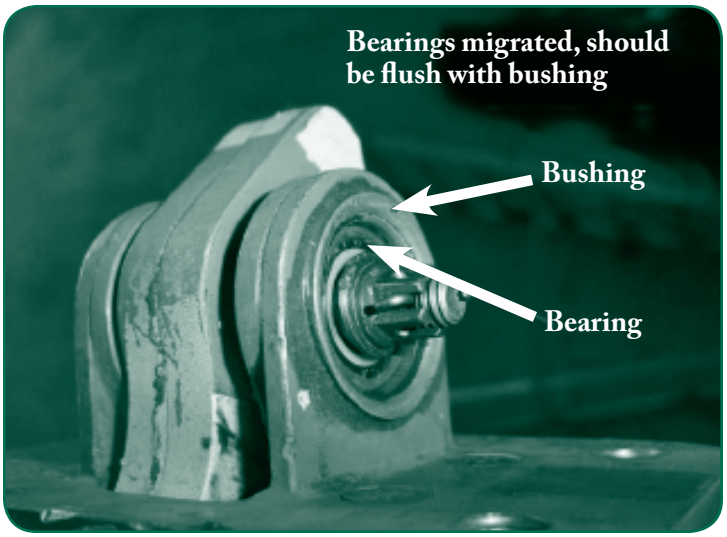
During the cleaning of the R/H wingtip navigation lights, it was noted that the #4 aileron hinge arm had a fresh sign of impact in the grease. The outboard portion of the aileron had approximately 1 inch of play in the up direction and ¾ inch of play in the downward direction.

Following removal of the aileron access panels, it was apparent that the bearings were out of their normal position. Removal of the aileron confirmed that the bearings had migrated out and also damaged the respective fitting. Minor fretting damage was also found to both the inboard and outboard side of the #4 hinge arm/bushing.

A precautionary inspection of the L/H aileron revealed worn bushings but fortunately no bearing migration had occurred. The pilot had not felt any control column vibrations or aileron flutter.

Transport Canada Comments:

Any mechanical defects occurring on a primary flight control is of significant concern. It is recommended that maintenance personnel check this area for bearing migration. This operator inspects the area every 9 months or 1 000 hours in accordance with their approved maintenance program. 🛠



BELL TEXTRON - CAN, 206B

SDR # 20090309002

Engine Mounts Severely Corroded

SDR submitted:

It was noticed after removal of the clamshell dampers and their packing material, during compliance of TB206-89-129 (removal of engine mount leg clamshell dampers), which is a customer option, that extreme corrosion was forming under the primer, which was found to be beyond limits.

All six engine legs were found corroded or damaged beyond limits. This was due to the engine mounts not being installed properly, which allowed the mount to become loose in the bushing bores and caused the clamshell to contact the engine leg.

Transport Canada Comments:

The damage on five of the legs would not have been found if the Technical Bulletin TB206-89-129 had not been carried out. There is no scheduled maintenance required by the manufacturer on the engine leg assemblies. 🛠

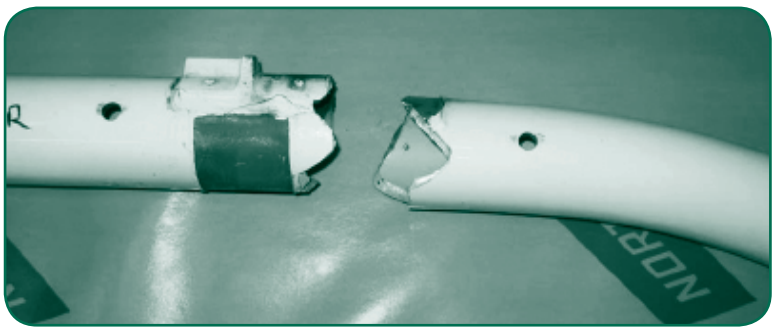
AGUSTA, A119

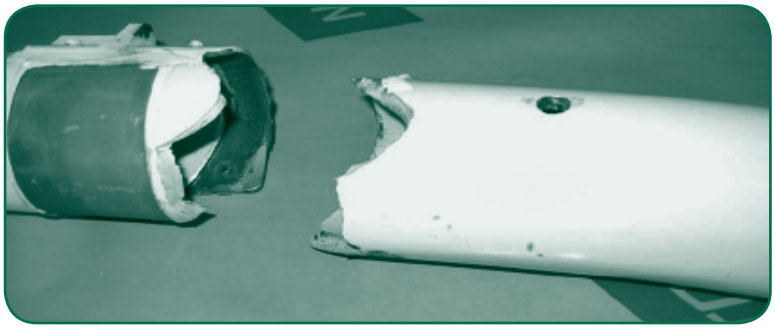
SDR # 20090512004

Sheared Crosstube

SDR submitted:

While climbing out from a landing area at approximately 70 knots the pilot heard a loud bang coming from underneath the pilot seat area. All engine parameters and flight controls were normal and the pilot landed as soon as practical. Once on the ground upon further investigation it was revealed that the forward landing gear crosstube had sheared at the right hand attachment saddle area.





Transport Canada Comments:

At the time of the occurrence the aircraft was equipped with an approved heli-utility basket that was found properly installed in accordance with the STC. 🛠

ROBINSON, R44 II

SDR # 20090515003

Hydraulic Pressure Relief Valve Failure

SDR submitted:

Following shutdown, the pilot noticed a severe hydraulic leak in the transmission area. The cooling air hose that is directed right at the hydraulic reservoir caused the fluid to be sprayed all around the transmission.

The pilot refilled the reservoir to the appropriate level in accordance with his servicing training, but it again lost approximately 250 ml of hydraulic fluid within an hour. A ground run leak check carried out by maintenance personnel, revealed the fluid level rose in the reservoir until it covered the entire sight glass, and continued to rise until it began to flow out of the "filler vent cap" quite rapidly. The reservoir was changed out and another ground run was performed, with no abnormalities or loss of fluid.

As the pump provides excessive hydraulic pressure to the system, it is suspected that the pressure relief valve incorporated into the reservoir assembly failed and was not recirculating any of the fluid back to the reservoir inlet. The pilot did not notice any adverse affect on his flight control system due to the fluid loss.

Transport Canada Comments:

The submitter updated the SDR as follows:

"Following replacement of the hydraulic reservoir, no further leakage was noted until a/f time 1699.2. It again began venting out of the reservoir cap. This time the hydraulic pump P/N D500-1 TTSN 1699.2 was replaced. Since then (current a/f time is 1736.9) no further leakage has been noted. The Pump has been sent back to Robinson for overhaul and evaluation. It is suspect that the pump gears were worn to the point of producing excess flow into the reservoir, but that cannot be determined until the teardown report is produced." 🛠

BELL TEXTRON - CAN, 407

SDR # 20090406005

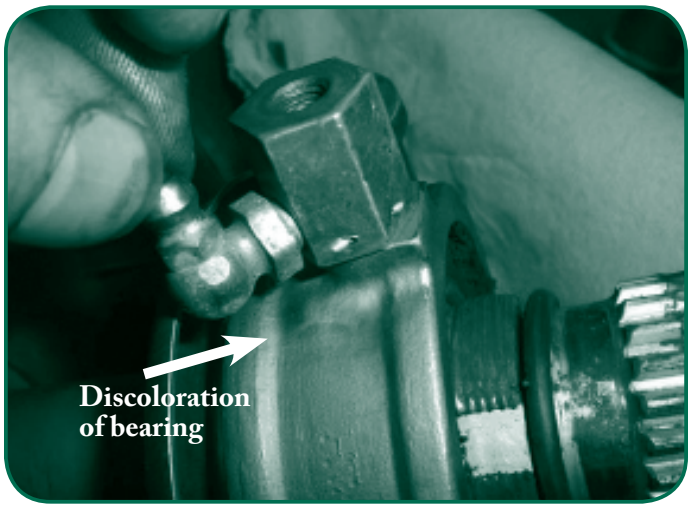
Overheated Tail Rotor Shaft Bearings

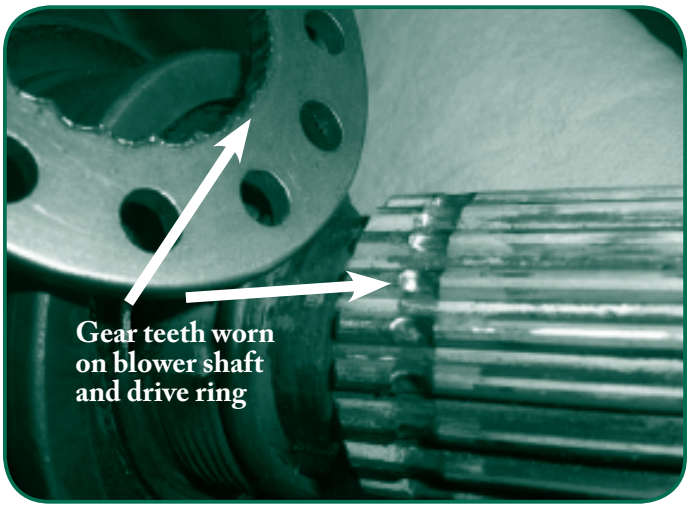
SDR submitted:

On a daily visual inspection of one company's Bell 407, the No. 1 T/R drive bearing hanger was found to be overheated with signs of blue discoloration.

The aircraft was removed from service. On further inspection the No. 1 and No. 2 bearings were found to be overheated and the root cause was found forward of the bearings, with the aircomm A/C pulley drive ring P/N S-3532EC-5 (STC No. SR00222DE), which had worn ninety percent of the drive ring and Bell T/R blower shaft P/N 407-040-320-101 mating teeth material away.

Due to the condition of the material the initial problem was not discovered but incorrect belt tension was questioned since all the other components to the system were serviceable.





ALLISON, 250-C47B

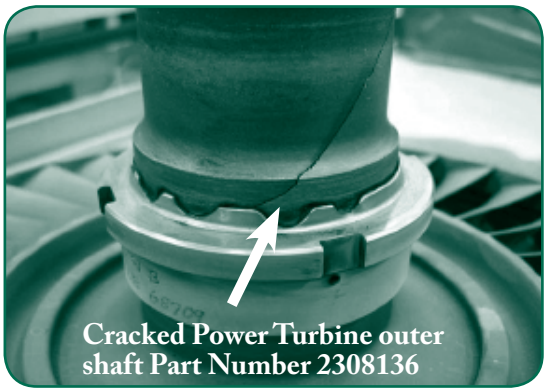
SDR # 20080325013

Engine Noise Observed During Engine Spool Down

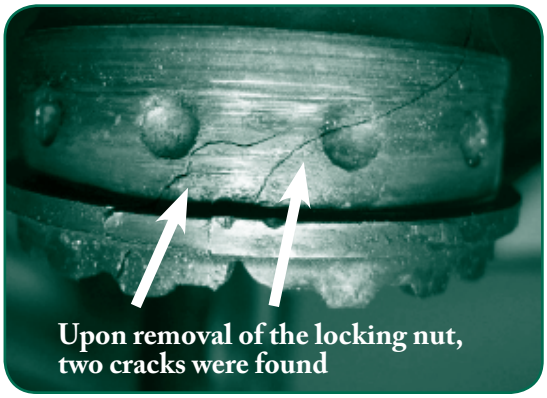
SDR submitted:

Engine noise was noted at ground idle. The noise was reduced when in hover but consistently appeared during spool down to ground idle. The engine was removed and returned to the overhaul shop for repair. The noise was confirmed during an engine test with vibration measurements. The engine was dismantled and inspection revealed a cracked power turbine outer shaft (Part Number 23038136). The crack affected the fit at the turbine 4th wheel curvics coupling, causing fretting and the loss of a coupling tooth.

Power turbine outer shaft and 4th turbine wheel were returned to the Type Certificate Holder for investigation.



Cracked Power Turbine outer shaft Part Number 2308136



Upon removal of the locking nut, two cracks were found

Transport Canada Comments:

Summary of the investigation noted "Previous engineering investigation into cracked Power Turbine Outer Shafts has determined that the most likely cause of the fretting that induces these cracks is loss of the clamp load between the curvics of the Power Turbine Outer Shaft and the curvics of the Fourth Stage Turbine Wheel". In this case, the cause for the lost torque of the spanner nut could not be identified. 🛠

GARRETT, TPE331-11U-612G

SDR # 20090617007

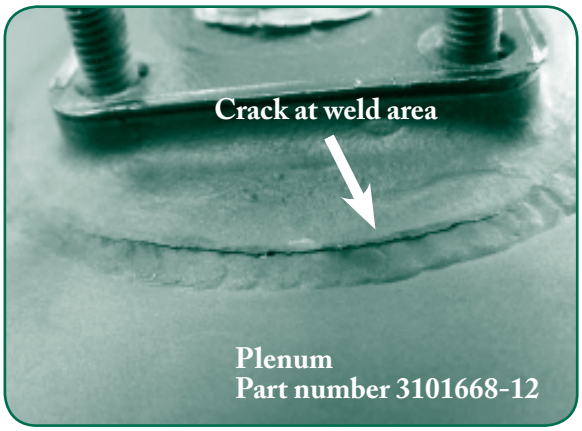
Cracked Engine Plenum

SDR submitted:

While conducting a major aircraft inspection, the Aircraft Maintenance Engineer noticed a crack on the plenum around the bleed air port of the R/H engine. The engine was removed and forwarded to the engine shop for repair. The part was replaced and the engine was reinstalled on the original aircraft.

Transport Canada Comments:

Other cases were reported through the Transport Canada Service Difficulty Reporting System. The Submitter noted that the plenum is not life limited and remains in service as long as it passes the visual and Non Destructive Testing inspection at overhaul. Honeywell has issued Service Bulletin (SB) TPE331-72-2014 to introduce an improved version of the plenum. Transport Canada recommends that maintenance personnel be extra attentive to this area of the TPE331 series engines and that owners and operators consider the incorporation of Honeywell SB TPE331-72-2014 at the next engine overhaul. Reference Service Difficulty Advisory AV-2006-07 issued 8 September 2006. 🛠



Crack at weld area

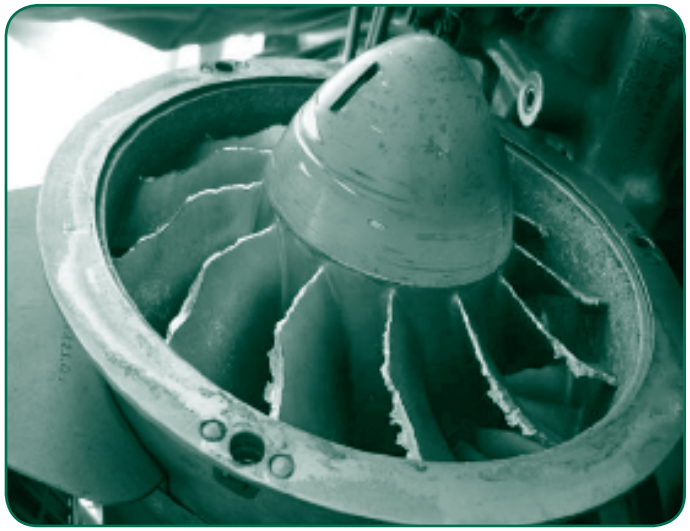
Plenum
Part number 3101668-12

AEROSPATIALE, AS 350B SDR # 20090318001

Compressor Damaged

SDR submitted:

Pilot was taking off from base, reported hearing odd whining from engine during takeoff and power changes. Aborted takeoff and returned to staging area. Opened engine cowl, noted aluminum shavings on engine deck. Visual inspection identified the compressor wash union Part Number (P/N) 350A54-1112-20 welded boss on intake assembly P/N 350A54-1080-04 had broken off and become ingested into the engine. Aircraft had been subject to scheduled inspection less than 10 hours prior, with no defects noted at that time. Aluminum shavings from welded boss were found ejected out of the bleed valve and out of the exhaust. The steel union did not get ingested, but bounced around in the intake plenum causing substantial damage to the axial compressor.



Propellers

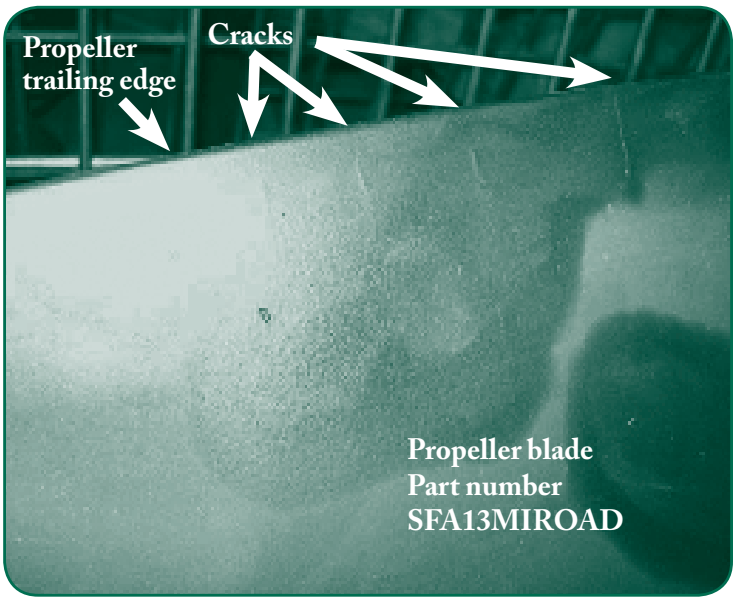
HAMILTON STANDARD, 14SF-7 SDR # 20090519005

Prop Moisture Ingress

SDR submitted:

During walk around, flight crew noticed an anomaly with the trailing edge of the #3 propeller blade on the L/H propeller. Maintenance was advised and inspected the propeller and determined that the trailing edge contained about 8 small cracks midway between the blade root and tip. When inspected further, what appeared to be moisture was noticed to seep from the cracks. When wiped away, moisture again would seep out.

Maintenance replaced the propeller blade and has contacted the overhaul/repair facility for possible causes for the cracking. A complete report on the nature of the defects has been requested from the repair facility. Company will review these findings and attempt to mitigate any re-occurrence, which may be associated with operational conditions.

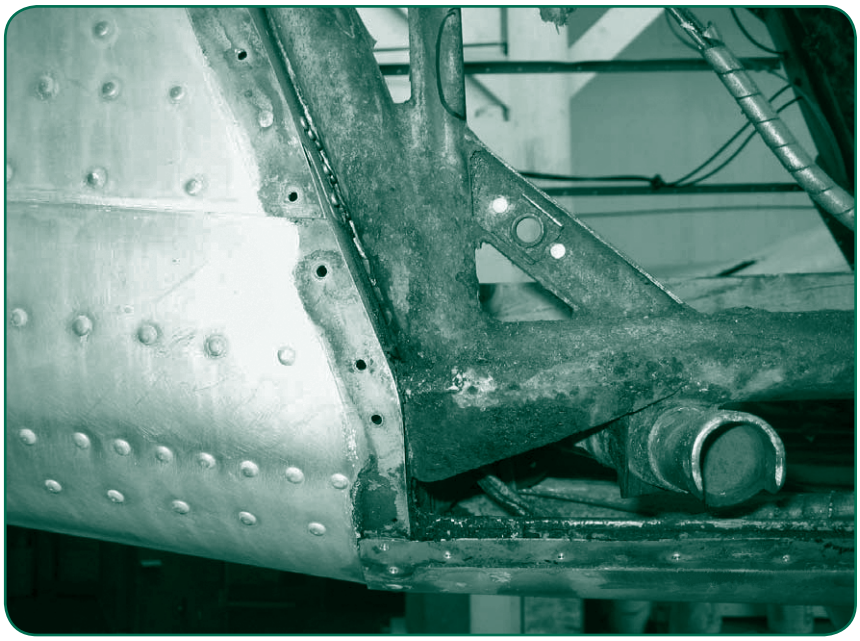


Transport Canada Comments:

The submitter has updated the Service Difficulty Report indicating that the cracks were in the paint only. 🛠

PA23 250 AZTEC SDR # 20090616012

Fuselage Frame Structural Tubing – Severe Corrosion



During an AMO maintenance inspection, technicians noted external corrosion on some of the fuselage frame tubes, specifically at the lower longeron tubes.

Initially, corrosion was found around the perimeter of the L/H (modified) cabin entry metal step plate. When the step plate was removed, deep corrosion pits were also noted in the fuselage skin. Significant exterior corrosion was found on several of the frame tubes. When removing the surface corrosion on frame tubes, a tube drain hole was unplugged and lots of rusty, sludge water drained out of the inside of the tube. This prompted the technicians to remove the fuselage skin in that area in order to inspect the outer (hidden) side of the frame tubes. The outer side of the tubes were found to be severely corroded and obviously beyond repair.

Eddy Current inspection on the frame tubes was carried out to determine wall thickness of the adjacent fuselage frame tubes. Many of the Eddy Current readings revealed a tube wall thickness well below the nominal wall thickness.

The fuselage frame tubes are the principal load carrying members of this aircraft, thus this particular aircraft was no longer airworthy. It is undetermined at this time if the aircraft is economically viable to repair to an airworthy condition due to extensive rework/jigging requirements.

Transport Canada Comments:

Almost all metals used in aircraft construction are subject to corrosion. This metal degradation is especially problematic when operating in a coastal environment as the aircraft is exposed to salt water/air spray. Areas around the windows must be properly sealed to prevent water/moisture from infiltrating and then migrating into the aircraft fuselage. Badly fitting doors and seals can allow water/moisture to enter the aircraft. In particular, the lower fuselage areas and any insulation blankets must be kept clean and dry. Additionally, ensure that all lower fuselage water drains are kept free to drain fluid overboard.

Transport Canada Civil Aviation (TCCA) reminds all aircraft owners/operators to take all preventive corrosion precautions in accordance with the respective manufacturers' instructions. The corrosion that was found on the subject aircraft was so pronounced that the structural integrity of the principal load carrying fuselage tubes was compromised. Fortunately, the maintainer took the responsible steps to expose and then inspect the hidden (inaccessible) areas and then carry out Eddy Current inspections to verify the problem. This work is commendable.

TCCA is in the process of requesting that the FAA advance our concerns to Piper to have the requirement for repetitive inspections added to Piper Service Letter (SL) 629, titled Fuselage Frame Tube Corrosion Inspection. 🛠

Equipment Airworthiness Directives (ADs)

Transport Canada (TC) endeavours to send copies of new airworthiness directives (ADs), which are applicable in Canada to the registered owners of the affected products. Equipment/appliance ADs are often only distributed to our regional offices because the owners of aircraft affected by this type of AD are not generally known.

AMEs and operators of the affected products are encouraged to obtain further information or a copy of the ADs from their regional TC office, their local TCC, their PMI, or from the Civil Aviation AD website at: www.tc.gc.ca/cawis-swimn

Manufacturer	AD Number	Origin	Description
