#### Abstract

Laurinolli, M.H., L.E. Harris, A. Bundy and L.P. Fanning. 2004. Compilation of Fish Stomachs Data from the Scotian Shelf and Bay of Fundy (1958-2002): CDEENA Diet Composition and Consumption Estimation Project, Can. Tech. Rep. Fish. Aquat. Sci. 2518: vi +90 pp.

This project was undertaken as part of the Comparative Dynamics of Exploited Ecosystems in the Northwest Atlantic (CDEENA) study. Its aim was to compile all existing and new fish stomach contents data in the Maritimes Region and to concurrently use this data to analyse diet composition and estimate fish consumption. The database currently consists of data for over 100,000 stomachs from 1958-2002 for 51 fish species. Diet composition was determined from stomach contents at the time of sampling. Food consumption was estimated using a gastric evacuation model. The gastric evacuation model downscales the consumption of harder to digest foods such as crabs, shrimps and echinoderms since these would be present longer in the stomach. This report documents the organisational structure of the database and provides a summary of the diet data available. Examples of the estimation of food consumption and diet for cod, haddock, and pollock are included. The compilation of stomach contents data for the region will facilitate further analyses and ecosystem modelling."

## RÉSUMÉ

Laurinolli, M.H., L.E. Harris, A. Bundy and L.P. Fanning. 2004. Compilation of Fish Stomachs Data from the Scotian Shelf and Bay of Fundy (1958-2002): CDEENA Diet Composition and Consumption Estimation Project, Can. Tech. Rep. Fish. Aquat. Sci. 2518: vi +90 pp.

Le projet décrit ici a été entrepris dans le cadre de l'étude intitulée "Comparative Dynamics of Exploited Ecosystems in the Northwest Atlantic (CDEENA) ". Il a pour but de réunir toutes les données anciennes et nouvelles sur les contenus stomacaux des poissons de la Région des Maritimes et de les utiliser pour analyser la composition du régime alimentaire et estimer la consommation des poissons. L'information que contient actuellement la base de données porte sur plus de 100,000 contenus stomacaux échantillonnés de 1958 à 2002, qui provenaient de 51 espèces de poisson. La composition du régime alimentaire a été déterminée à partir des contenus stomacaux lors de l'échantillonnage. La consommation alimentaire a été quant à elle estimée d'après un modèle d'évacuation gastrique. Ce modèle minimise la consommation des aliments durs à digérer, comme les crabes, les crevettes et les échinodermes, ces aliments restant présents plus longtemps dans l'estomac. Le présent rapport documente la structure organisationnelle de la base de données et fournit un résumé des données sur l'alimentation qui sont disponibles. Il comporte des exemples d'estimation de la consommation et du régime alimentaires de la morue, de l'aiglefin et de la goberge. Le rassemblement des données sur les contenus stomacaux pour l'ensemble de la Région facilitera l'exécution d'analyses plus poussées et la modélisation de l'écosystème.

## 1 INTRODUCTION

A multi-year study entitled Comparative Dynamics of Exploited Ecosystems in the Northwest Atlantic (CDEENA) was undertaken by DFO to look at changes in the structure and function of ocean ecosystems over time and determine how these may have affected fish productivity. This project uses ecosystem-level models to investigate effects of environmental variation, predation, and fishing on changes in reproduction, mortality, growth and feeding. These changes in ecosystems can include changes in trophic structure which are reflected in changes in predatorprey interactions.

The ontogenetic, seasonal, annual, and geographic variation in predator-prey relationships are being investigated through the reconstruction of fish diet compositions and daily consumption for major predators based on stomach contents. The resulting information will provide basic biological information on the feeding habits of major predators found on the Scotian Shelf. This diet composition and consumption information will also be used as input to ecosystem models that describe temporal and spatial variation in energy fluxes through different ecosystems.

The reconstruction of fish diets is accomplished through the collection and analysis of stomach contents and the subsequent estimation of diet composition and daily consumption for the predators. At the beginning of this project, there were data from fewer than 1,800 fish stomachs from the eastern Scotian Shelf available. These stomachs were taken from cod, haddock, and white hake caught during research vessel and industry surveys. This project followed two parallel lines of investigation. First, an enhanced stomach collection program was put in place to acquire fish stomachs from both research and commercial activities and to process the resulting samples. The second approach was a concerted effort to locate any and all existing stomach sample data, reprocess it into standardised electronic formats and make them available in the same manner as the new data being collected concurrently.

Stomachs from only three species of predators have been collected on the eastern Scotian Shelf since 1996. In the summer of 1999, a three year enhanced fish diet sampling program began. This program targeted 32 species of common commercial and non-commercial fish of the Scotia-Fundy region. Samples were collected during research surveys (spring and summer groundfish, herring), industry surveys ( 4 VsW sentinel, halibut), and commercial fishing (observer and Fishermen and Scientists Research Society (FSRS) sampling). The stomach collection was done in partnership with other researchers, members of industry, and the FSRS. All stomach contents were analysed by FSRS technicians. In addition, data from the Trawl Impact study (Kenchington et al. 2003) and from the commercial shark fishery (Joyce et al. 2002) were made available. The enhanced stomach collection program has amassed new diet data from over 20,000 stomachs.

During investigation of archival data, stomach content data were uncovered and restored from a variety of sources including: the pre-1970's fisheries surveys (1958-1969, Halliday and Koeller 1981); Fisheries Ecology Program surveys (1982-1983); a swordfish survey (1980); pollock surveys (1983-1988); juvenile haddock surveys (1989); a juvenile fish survey (1988); a silver hake survey (1981-1986, Waldron 1988); and groundfish surveys (1995-1996, Halliday and Koeller 1981). The format of this information ranged from hard copy to frozen fish collected for other research to preserved stomachs. These sources provided information from almost 84,000 fish.

The data collected came from many different sources and were in various formats. A stomach contents database was designed in Oracle to provide a single, secure location for the data. This database is linked to the original data tables, where possible, to make current set and fish detail sampling information available. This database provides a consistent format and increased accessibility to stomach data.

Finally, historical and current fish diet compositions and daily consumption estimates were reconstructed based on the stomach data. Diet composition was estimated from stomach contents at collection time. Because digestion rates are prey specific, gastric evacuation rates and models from the literature were used to estimate and adjust daily consumption based on these stomach contents. Diet composition was then re-calculated from these daily rations and compared to diet compositions in the stomachs without any correction for gastric evacuation differences.

## 2 METHODS

### 2.1 Data Sources

A summary list of all the data sources, including the codes used to identify the data in the stomach database and the years of coverage of the samples, used in this project is provided in Table 1. Table 1 is separated into the three types of stomach data sources to be described in this section of the report. The first data source includes stomachs collected during various sampling programs. The second data source contains stomach data obtained from previous diet research. The third data source includes other data available that have not yet been added to the stomach database. In the more detailed descriptions to follow, the current custodian refers to the holder of the data though most of these data (except where specified) are available through the stomach database in Oracle. Permission to use any data should be requested from the Marine Fish Division.

Table 1. Data sources and identification code (Database ID) used for the stomach contents database.

| Data Source | Database ID | Years |
| :--- | :--- | :--- |
| Stomach Sample Sources: |  |  |
| Enhanced Sampling Program: |  | $1995-$ Present |

### 2.2 Stomach Collection Protocol - Enhanced Sampling Program

Generally, a consistent protocol was followed during the enhanced stomach sampling program. The goal was to collect samples from a wide spectrum of species, with good predator size range (including juveniles) and geographic coverage. An example of the sampling request can be found in Appendix I. Fish were sampled on a length-stratified basis per set following the Scotia-Fundy groundfish surveys protocol. That is, for most species one fish per $1-\mathrm{cm}$ length group was sampled. The flounders and plaice were sex and length stratified providing 2 samples per $1-\mathrm{cm}$ group. When the selected fish were sampled, a visual estimate of stomach fullness was recorded. For the most part, only stomachs with contents were retained. The occurrence of empty, regurgitated, and everted stomachs was recorded. These stomachs were not replaced with full stomachs for the size class, thus not all sizes caught were represented by a collected stomach.

The stomachs were carefully excised by first cutting below the pyloric sphincter and then as high up the oesophagus as possible. The stomachs were then placed in brine in order to stop digestion and also to preserve the specimen. Large stomachs were split to allow the brine to enter. Stomachs were bagged and labelled individually. When a freezer was available, the samples were frozen at sea. Otherwise they were frozen as soon as they were brought back to the lab. There may have been some water loss to the contents due to the brine and/or the freezing, however no adjustments were made to the content weights to compensate.

### 2.3 Stomach Contents Analysis - Enhanced Sampling Program

All the stomachs collected during the enhanced stomach sampling program were analysed by FSRS technicians. After thawing, the stomachs and contents were drained on a fine mesh strainer. Prey items were sorted, identified, and measured. Prey length was always assumed to be for intact prey (e.g. fork length for fish, carapace width crabs). The Scotia-Fundy research species codes have been used since 2000 in order to maintain consistency and to reduce confusion caused by using common names. The data were recorded on the stomach analysis datasheet (Appendix II). These data were then entered into the stomach database edit tables through the Marine Fish Division Virtual Data Centre (VDC) website. Samples were assigned an individual identification number called sample index number. This is important for tracing data back to the original hard copy. It also provides a unique identifier for each sample and links the fish detail information with its stomach contents. A detailed account of the stomach content analysis protocol is in Appendix III.

The level to which prey were identified depended on the prey type. All fish as well as commercially important crustaceans and molluscs were identified to species, state of digestion permitting. Broader categories were used, such as class or even phylum, for prey that were less common or were more difficult to identify. There is a trade-off between the number of stomachs analysed and the taxonomic level of identification and an effort was made to process all the stomachs collected each year.

### 2.4 Stomach Collection and Analysis - Other Sources

The historical data and stomach samples provided by other researchers were collected under a variety of sampling regimes. In most cases, the details or protocols of collection and analysis are not available. The information that is currently known is described here.

The 1988 juvenile fish survey in the Scotian Shelf basins and on Georges Bank included stomach collection and preservation from adult fish for description of trophic interactions between scattering layers of zooplankton.

Stomachs were collected in 1997-1999 during a trawl impact study in the 4TVW Haddock Closed Area on Western Bank using an Engel 145 otter trawl. Two sampling protocols were followed. In the first, thirty stomachs were collected per species per trawl set on a length-stratified basis ( $\mathrm{N}=$ 1432). Of these stomach samples analysed, $75 \%$ were analysed to a general level and the remaining $25 \%$ to the species level (MacIsaac pers. comm.). A second data set ( $\mathrm{N}=444$ ), that was not length-stratified, consisted of seven samples per focussed species (cod, haddock, American plaice, yellowtail flounder, and winter flounder) per set for detailed stomach contents analyses to species, genus or family level (Kenchington et al. 2003). In both cases, food in the esophagus was pushed into the stomach and dissected stomachs were preserved in hypersaline solution and frozen. Empty, everted or ejected stomachs were recorded but not collected. These data may not be appropriate for modelling fish diet in the wild due to the design of the survey. The trawl repeatedly sampled the same area. With each pass, animals were crushed making them available to species that do not ordinarily feed on them. For example, the remnants of a large clam may have been found in the stomach of a haddock.

In the late 1950s to 1970, research surveys on basic biological information and fish distribution also included feeding studies. The stomach collection and contents analysis protocols are not known in detail, however samples were analysed at sea and recorded onto data sheets that were then key punched to fixed format 80 column cards and stored at the St. Andrews Biological Station.

Haddock stomachs were collected for feeding studies during 1982 and 1983 seasonal groundfish surveys as well as on dedicated 1983 Fisheries Ecology Program research surveys. These bottomtrawl surveys followed a depth-stratified random sampling design. Two to five fish were sampled per $2-\mathrm{cm}$ length group. Empty or damaged stomachs were not collected however their numbers were recorded. In some cases, whole haddock were frozen.

During the 1983-1988 pollock distribution and abundance surveys stomachs were collected from a number of species but most were from pollock. The data were recorded at sea on data sheets. The details of the data vary, for some stomachs only the main prey item was listed and for others each prey item was weighed and counted. Some more collection and analysis details are provided in section 3.1.2.3 in the Results.

Silver hake stomachs collected by Waldron (1988) in the 1980s consisted of one fish per sex per 1 cm length class. Gut fullness was subjectively recorded, then stomachs were removed and injected with $10 \%$ buffered formalin. Wet stomachs were weighed and then contents were washed over a $10-\mu$ sieve, sorted to the lowest possible taxa and weighed to the nearest centigram. The total number of specimens per taxonomic group was also recorded. Samples taken by observers aboard trawlers were quick-frozen as whole fish for 2 min at $-20^{\circ} \mathrm{C}$ and then stored at $-40^{\circ} \mathrm{C}$ in the lab for analysis within one month of capture. These samples augmented the formalin preserved samples where they were minimal. Contents descriptions were less detailed and items were sorted into 27
major taxa except whole fish prey were identified to species. The other prey groups were dried at $90^{\circ} \mathrm{C}$ for 24 h and weighed.

### 2.5 Stomach Database

The diet information used in this project came from a variety of sources and data formats. A stomach database was created in order to keep the data in a single, secure location. This also increased accessibility to other researchers.

The Oracle database has been separated into edit tables and production tables in the 'Groundfish' account. This allows for the editing of the data before they are added to the main data tables that are accessible to users. Error checks are performed on the edit tables before they are incorporated into the final production tables. The database contains three types of tables (Fig. 1): the first holds the set INFormation such as time and location (Fig. 2), the second holds the DETail information on each fish (Fig. 3), and the third holds the information on STOmach contents (Fig. 4). The edit tables found on Oracle are 'sdinf_edit', 'sddet_edit', and 'sdsto_edit'. The production tables are 'sdinf', 'sddet', and 'sdsto'. There is also a consolidated view (sdview1) that combines variables from all three tables to facilitate data extraction. A full description of the database and the data management protocols can be found at the Marine Fish Division website (http://marvdc.bio.dfo.ca/pls/vdc/mwmfdweb.splash).

The Oracle database also contains tables that describe the codes used in the above tables. Table 'sdsource' (Fig. 5) lists the codes used for each data source type and a description of the survey type. These data sources are the same as those stated in Table 1. The stomach fullness codes in table 'sddet' are described in 'sdfullness' (Fig. 6) and the digestion codes in table 'sdsto' are described in 'sddigest' (Fig. 7). The table 'sditem' contains the numeric codes and names of the prey items found in the stomachs (Fig. 8). The column 'tech' in 'sddet' has the code for the technician(s) who analysed each stomach and their corresponding names are listed in 'sdtech' (Fig. 9). Two other useful tables are 'sdpred' and 'sderred'. Table 'sdpred' lists the predator species codes and names from which stomachs have been collected. Table 'sderred' lists numeric codes and descriptions for the numbers in the 'status flag' columns. These numbers are automatically entered into edit tables when an error in the database is encountered. This automatic error detection however may not detect all the problems. The edit tables should be examined further and all corrections made before promoting the data to the production tables.

### 2.6 Consumption and Diet Estimation

Gastric evacuation calculations can be used to determine relative rates at which different prey species are evacuated from the stomach and thus estimate amount of food consumed. Gastric evacuation is defined as the expulsion of food broken down through a combination of muscular contractions of the stomach wall and enzymatic action from the stomach through the pyloric sphincter into the small intestine (Bromley 1994). The estimation of feeding using gastric evacuation studies is based on the input equals output rule. This rule assumes that, averaged over time, the amount of food leaving the stomach is equivalent to the amount of food consumed. The application of experimentally derived gastric evacuation rates to wild populations also assumes that food passes through experimental fish at the same rate as in the wild. Gastric evacuation models, in conjunction with stomach content data from fish in the wild, can be used to estimate total consumption and the proportion of the different prey items consumed by fish populations in order to quantify feeding interactions among species. For our analysis, gastric evacuation rates were taken from the literature to estimate consumption. Percent diet composition was estimated from stomach contents analysis.

The consumption model of dos Santos and Jobling (1995) based on experiments with cod was used to calculate consumption rates (per day) and then estimate diet composition. Although the parameters in their model were derived from experiments on cod, they were applied here to other species of fish as well. It is unlikely that all the species sampled had the same evacuation rate, however temperature and prey type seemed to be more important than predator species in determining rates. Jones (1974) found no significant differences in gastric evacuation rates of cod, haddock and pollock fed the same prey species. Durbin and Durbin (1980) found in their review of feeding experiments that temperature and prey type, not predator species, were the most important factors influencing gastric evacuation rates. Gastric evacuation rates for other species are available in the literature however the lack of standardisation in experimental design makes it impossible to
compare among species, or even among studies for a single species. Most gastric evacuation models are based on single-meal experiments though a second meal can alter evacuation pattern of the first meal. Feeding methods can also have an effect on gastric evacuation. Some experiments starve fish beforehand and use different prey types (species) or preparations such as live, fresh, frozen, chopped, or in pellets. Fish have been fed to satiation, a set meal size, or force-fed (rarely). Water temperature, predator size and life stage can also have an effect.

The expected consumption of grams of species $i$ per day $\left(C_{i}\right)$ is given by dos Santos and Jobling (1995) as:

$$
C_{i}=\frac{24 \ln 2 e^{\gamma T} B^{\delta} S_{i}}{\alpha_{i}\left(\Sigma S_{i}\right)^{\beta}},
$$

where $T$ is water temperature, $B$ is body size (in this case length), and $S_{i}$ is the weight of species $i$ in the stomach. The rate of gastric evacuation increases exponentially with temperature. The term $\left(\Sigma S_{i}\right)^{\beta}$ approximates the slowing of evacuation with increasing initial meal size. The constants $\beta, \gamma$, and $\delta$ were taken from dos Santos and Jobling (1995) as estimated through food consumption experiments using cod where $\beta=0.48, \gamma=0.13$, and $\delta=0.46$. The term $\alpha_{i}$ is the prey-specific halflife (hours) for evacuation of each food type. The values used for this term were also taken from dos Santos and Jobling (1995) and extrapolated for other species not used in their model as described below.

The prey items were separated into the groups being used in CDEENA ecosystem modelling with Ecopath (Table 2). A list of all items found in the stomach database and the Ecopath group to which they were assigned can be found in the Oracle table groundfish.sd_ecopathcode. Consumption calculations were based on these groupings. Many of the prey found in the stomachs were not included in dos Santos and Jobling's experiment. These were assigned half-life parameters $\left(\alpha_{i}\right)$ according to their similarity in size and taxonomy to those present (Table 3).

${ }^{3}$ Half-life calculated as average of fish listed above.
${ }^{4}$ Half-life calculated as average of all species listed above.

Some adjustments were made for weights of prey with large amounts of non-digestible inorganic material. For echinoderms, no empirical data were available to calculate the proportion of digestible and non-digestible materials. Species specific conversions were rejected because this would add a level of complexity that may not add any real information. The most common species in the diets were brittle stars which can be up to $90 \%$ exoskeleton (Mark Hansen 2001, pers. comm.). After discussion with CDEENA researchers in other areas, a conversion factor of 0.6 for echinoderm prey weights was agreed upon. Although this is lower than the estimated proportion of exoskeleton, other species are not adjusted to reflect their make up of organic versus inorganic matter.

Molluscs also have a large amount of non-digestible material. Pieces of shells that were eroded or that had no flesh attached were classified as 'molluse remains' as were opercula and squid beaks. These items can take many days to pass through the digestive system and would result in overrepresentation of molluscs in the diet. In order to calculate a conversion factor from total weight of bivalves to soft tissue weight, all bivalves caught during NED2001004 were collected, measured and weighed. The length, width, and height in centimetres and the whole weight, shell weight, and soft tissue weight in grams were recorded. A general conversion factor was then calculated based on all bivalves combined. Most of the bivalves caught were scallops since a bottom trawl was used (sea scallop $n=24$, Iceland scallop $n=128$, mussel $n=1$, Iceland cockle $n$ $=1$, unidentified clam $n=1$ ). A linear regression without the constant was used to calculate the conversion from total weight to soft tissue weight:
soft tissue weight $=0.421 *$ total weight $\left(r^{2}=0.986\right)$.

Crabs were split into two groups based on the minimum size found in predator stomach contents: small crabs (less than 50 mm carapace width) and large crabs (greater than 50 mm carapace width). This is lower than the size split originally used for the Scotian Shelf ( 95 mm carapace width) which was based on recruitment to the fishery, size at maturity and ontogenetic changes in diet.

### 2.6.1 Consumption Calculations

The stomach data currently stored in Oracle was used in consumption and diet estimation. Preliminary analyses were restricted to groundfish survey data in the 4 VsW and 4 X NAFO divisions. Calculations were done in SQL*Plus (Structured Query Language Plus 8.0). A detailed description and flowchart of the SQL process used is given in Appendix IV. The scripts used in SQL are given in Appendix V. The general process is:

During groundfish survey stomach collection, empty stomachs were not collected in most cases. Some empty stomachs were collected and also some stomachs thought to have contents were then found to be empty during analysis. The same applies to stomachs designated as everted ('S5' or ' 55 ' in GS database or with fullness $=5$ in stomach database). For fish population consumption estimation, all empty and everted stomachs must be included to account for fish that were not feeding. Thus, empty and everted stomachs not included in the stomachs database had to be counted from the groundfish survey (GS) database, being careful not to duplicate counts from both databases.

The total numbers of fish surveyed were also calculated from the GS database. The data were first grouped into $5-\mathrm{cm}$ length groups due to small sample sizes at $1-\mathrm{cm}$ length classes. Standardised counts at $5-\mathrm{cm}$ length groups were obtained from Oracle table NWAGS.gsd5lf_mv that is based on total counts of fish in the groundfish surveys. These numbers were used to bump up consumption estimates from the samples up to the population level.

The data were also separated by NAFO division and season (spring and summer). Consumption and diet composition was calculated for division 4 VsW and calculations are in progress for 4 X . The prey items in the stomachs were converted to estimates of prey amounts consumed per day per $5-\mathrm{cm}$ length class by predator species based on dos Santos and Jobling (1995) as described earlier. The total population ration eaten per species per length class was calculated by summing across strata based on the number of net tows, the strata areas and tow area coverage. Average ration per fish was then estimated by the total ration divided by the total number of fish. Diet composition by percentage was then calculated from these results.

A final step in the process was to interpolate rations for length classes that were surveyed but for which no stomach analyses were performed. It was necessary to include all lengths existing in the population for the Ecopath ecosystem modelling that occurs subsequent to the work described here. This was done in Excel by averaging rations for lengths above and below the missing length class. Consumption calculations were also made with the 1999 and 2000 stomach data pooled together to reduce the numbers of missing length groups.

Diet composition was also calculated without using the dos Santos and Jobling (1995) gastric evacuation equation. The proportions of prey items in the stomachs were assumed to be the same as the proportions eaten by the fish and thus digestion of each item was assumed to be the same. Actual consumption could not be estimated since it was not known how long the food was there and what the rate of digestion was. These values were then compared to the diet compositions determined after using the gastric evacuation model.

## 3 RESULTS

### 3.1 Data Sources

Stomach data were obtained through various collection methods. For each data source type currently in the stomach database, stomach counts are given by species and NAFO division collected in. Where available, information is provided on: the original investigator of the research; who the data was obtained from; the current custodian of the data; the format of the data when it was received; the current format and location of the data; and citable references for methodology and data products.

Counts of all the stomach data available in the stomach database by species and era are given in Table 4. A total of 100,350 stomachs are included of which the majority are from cod and haddock, especially in the pre-1970's data set.

Table 4. Counts of stomach data available in the stomach database by species and era.

### 3.1.1 Stomach Sample Sources

### 3.1.1.1 Groundfish research surveys: GS (1995 - present)

Original investigator: Marine Fish Division (MFD)
Received from: MFD
Current custodian: Alida Bundy (stomach data), Joe Hunt (survey data)
Received format: Oracle tables
Current status: Oracle tables (stomachs database, groundfish database - GS)
Reference(s): Halliday and Koeller (1981)
Stomachs were collected during the annual March 4 VsW cod survey (Table 5) and the July groundfish research survey (Table 6). Standard depth-stratified random groundfish surveys began in 1969 to improve assessment accuracy for fisheries management purposes (Halliday and Koeller 1981). The sampling of 4 VsW cod began in 1996 and the sampling program has now been expanded to include over 30 species from the Scotian Shelf and the Bay of Fundy. Fish stomachs were examined on a length-stratified basis during a stratified random bottom trawl survey. Stomach fullness was assessed visually and any stomachs found to contain food were preserved in brine and frozen at sea. In most cases, empty stomachs were not collected and these records are only in the groundfish database, not the stomach database. Mackerel and herring were collected and frozen whole for detailed sampling in labs at Maurice Lamontagne Institute and St. Andrews Biological Station respectively. Any stomachs with contents were then shipped back to the Bedford Institute of Oceanography (BIO) for analysis by FSRS technicians.

### 3.1.1.2 Herring Research Surveys: PS (1999-present)

Original investigator: Mike Power-SABS
Received from: Mike Power
Current custodian: Alida Bundy (stomach, catch data), Mike Power (set, hydro data)
Received format: Oracle tables
Current status: Oracle tables (stomach database, pelagic survey database - PS), Excel (catch data)
Reference(s): Melvin, G. and M. Power. 1999. Herring Acoustic Survey Report: CGS Alfred Needler - N99-55, N99-60. Department of Fisheries and Oceans, Biological Sciences Branch, Maritimes Region, 6 pp.

This survey included sampling with ichthyoplankton gear, bottom trawl, and hydro-acoustic gear in October and November 1999 and 2000 to survey the distribution and abundance of herring on Georges Bank and the Scotian Shelf. Stomachs were collected in 4 VsW and 5 Z from the bottom trawl catches for a variety of species (Table 7). For species with 50 or fewer specimens caught in a set, the entire sample was examined, time permitting. When more than 50 specimens of a species were caught, 50 fish with a good range in size, including juveniles were selected. Stomach fullness was assessed visually and any stomachs found to contain food were preserved in brine and frozen at sea. Stomach contents were analysed by FSRS technicians.

Table 7. Stomachs in database collected during herring surveys.

### 3.1.1.3 4VsW Sentinel Surveys: SS, JSS (1996-present)

Original investigator: Paul Fanning and FSRS
Received from: FSRS
Current custodian: Alida Bundy
Received format: Oracle tables
Current status: Oracle tables (stomach database, industry survey database - ISDB) Reference(s): none

Stomachs were collected in the fall from 1996 to the present during the annual 4 VsW Sentinel Survey. This long-line survey includes inshore areas (strata $467,468,460$ ) as well as the offshore areas covered by the annual groundfish surveys. The survey includes two parts: a stratified survey done by crewmembers (SS) and sometimes observers (JSS); and a commercial index portion where samples are collected by observers at sea (CI) or directly from fishermen on shore (CS). For the stratified survey, stomachs are examined during the routine detail sampling of selected species in the catch to visually determine stomach fullness. Any stomachs with contents are preserved in brine and returned to the FSRS for analysis. The numbers of stomachs examined by species are given in Table 8. The commercial index portion of the survey is described in subsection 3.1.1.5.

### 3.1.1.4 Halibut Industry Survey: HS (1999-present)

Original investigator: Kees Zwanenburg
Received from: FSRS
Current custodian: Kees Zwanenburg
Received format: Oracle tables
Current status: Oracle tables (stomach database, ISDB)
Reference(s): Zwanenburg et al. (2003); Zwanenburg and Wilson (2000)
Halibut and a few other species were collected during the halibut industry survey (Table 9). The halibut survey takes place from May to July from the Grand Banks to southwest Nova Scotia. Stomachs were sampled on a length-stratified basis. Stomachs with contents were preserved in brine and returned to the lab. The contents were analysed by FSRS technicians.

### 3.1.1.5 Commercial Index: $\mathrm{CI}, \mathrm{CS}$ (1997-present)

Original investigator: Paul Fanning and FSRS
Received from: FSRS
Current custodian: Carl MacDonald, FSRS
Received format: Oracle tables
Current status: Access database, Oracle tables (stomach database, ISDB)
Reference(s): none
Fish are collected by observers at sea ( CI - Commercial Index observer coverage) and by shorebased collection from fishermen (CS - Commercial Index Sampling) from a number of species during the commercial index phase of the 4 VsW sentinel survey (Table 10). The FSRS technicians process the stomach samples.

### 3.1.1.7 Browns Bank Survey: SP (2000)

Original investigator: Peter Hurley
Received from: Peter Hurley
Current custodian: Peter Hurley
Received format: Access database
Current status: Oracle tables (stomach database)
Reference(s): none available
Stomach samples were collected during a single set on Browns bank (4X) in February 2000 during the Georges Bank spring groundfish survey N965 (data designated as N965BB in stomach database) to collect haddock samples for Peter Hurley for maturity and condition analyses and cod for Don Clark. This data supplied 242 stomachs to the database of which 75 were from cod and 167 were from haddock.

### 3.1.1.8 Juvenile Fish Survey: SP (1988)

Original investigator: John Neilson
Received from: John Neilson
Current custodian: Paul Fanning
Received format: stomach samples
Current status: Oracle tables (stomach database)
Reference(s): Neilson, J. 1988. Cruise Report: Alfred Needler - N104. Department of Fisheries and Oceans, Marine Fish Division, Biological Sciences Branch, Science Sector, 4 pp.

Ten buckets of fish stomachs and whole fish preserved in formalin from cruise N104, 13-30 June 1988, were found in storage. These samples were taken primarily from Emerald and LaHave

Basins and from Georges Bank. The purpose of the cruise was to study the occurrence of juvenile fish in basins on the Scotian Shelf and to determine trophic interactions with high concentrations of zooplankton. It was also the first year of a midwater survey of abundance of age-0 gadids on Georges Bank. Most of the stomachs were from silver hake and spiny dogfish (Table 12). Other species included argentine, monkfish, witch flounder, cod, haddock, pollock, squid, hakes, and alewife.

Table 12. Stomachs in database from the 1988 Juvenile Fish Survey.

### 3.1.1.9 Trawl Impact Study: TIS (1997-1999)

Original investigator: Ellen Kenchington
Received from: FSRS
Current custodian: Ellen Kenchington, Kevin MacIsaac
Received format: Oracle tables
Current status: some in Oracle tables (stomach database), some not yet available
Reference(s): Kenchington et al. (2003)
Stomachs were collected during this study of the effects of mobile fishing gear on demersal fish and benthic habitat (Kenchington et al. 2003). This bottom trawl survey was conducted within the 4TVW Haddock Closed Area on Western Bank. Only the stomachs collected in 1999 were analysed by the FSRS and so only these data are currently available in the database. These consist of 608 stomachs collected on cruise N99-013A. More data (another 1268 samples) are expected to become available from the Marine Environmental Sciences Division (MESD). Table 13 lists stomach numbers from 1998-1999 including those not yet entered into the stomach database. The
amount of data collected in 1997 is unknown at this time. These data may not be appropriate for modelling fish diet in the wild due to the design of the survey. The trawl repeatedly samples the same area. With each pass, animals are crushed making them available to species that do not ordinarily feed on them. For example, the remnants of a large clam may be found in the stomach of a haddock.

Table 13. All stomachs collected during the trawl impact study 1998-1999.

Received format: Oracle tables created from original data sheets and key punched cards
Current status: Oracle tables (stomach database)
Reference(s): Halliday and Koeller (1981);
Branton R., K. Zwanenburg and Joann Smith DDA Computer Consultants. 2000. Pre 70 groundfish research trawl data base "draft development plan". Department of Fisheries and Oceans, Virtual Data Centre.

The pre-1970s bottom-trawl surveys were exploratory in nature and their purpose was to increase basic biological knowledge on distribution and stock boundaries of exploited species (Halliday and Koeller 1981). The area surveyed was generally within 4TVWX, focussing on 4VW. From 1958 to the mid-1960s, seasonal surveys for the "Gulf Census" in the Gulf of St. Lawrence were used to determine recruitment and environmental effects on abundance, distribution and movements of cod and plaice. Survey coverage was extended from 1960-1964 into division 4V. On the Scotian Shelf, cruises initially focussed on haddock abundance and distribution from 1959-1966. Between 1966 and 1970, surveys explored underexploited species such as silver hake, sandlance and argentine. In the 1960 s, research surveys also included studies of diurnal migration and behaviour, species
associations, feeding, trawl engineering and hydro-acoustics. The stomach collection and contents analysis protocols are not known in detail, however samples were analysed at sea and recorded onto data sheets that were then key punched to fixed format 80 column cards and stored at the St. Andrews Biological Station (Branton et al. 2000). After 1970, seasonal standardised stratified random sampling on groundfish surveys began for more accurate assessments for fisheries management, however stomach sampling was ceased until 1995.

Stomachs were collected during 54 groundfish surveys between 1958 and 1969 , with good seasonal coverage. The data cover 42 species of fish with cod and haddock being the most sampled (Table 14). Predator length, but not weight is available. Prey weight, but not length is available. The data do not appear well edited; there are predator species listed that do not normally occur in the region. These may be miscoded or possibly the codes have changed since this time period. Samples of 'Bonaparte' are likely miscoded since this species is very rare in the Northwest Atlantic. It is possible that these stomachs were from redfish (codes 20, 21, and 23) since the Bonaparte is code 22 and since redfish, a commonly caught species, was not otherwise present in the pre-1970's stomach data.

Table 14. Numbers of stomachs examined during the pre-1970's surveys. These include full and empty stomachs.

### 3.1.2.2 Fisheries Ecology Program: FEP (1982-1983)

Original investigator: Ken Waiwood, Robin Mahon
Received from: Mark Showell
Current custodian: Mark Showell
Received format: ASCII text file
Current status: Oracle tables (stomach database)
Reference(s): Mahon, R. and M. Buzeta 1983. Cruise Report: Lady Hammond - H088, H089. 1983. Department of Fisheries and Oceans, Atlantic Fisheries Service, Marine Fish Division, Fisheries Research Branch, Scotia-Fundy Region, 4 pp.

Waiwood, K. 1983. Cruise Report: Alfred Needler - N010. Department of Fisheries and Oceans, Atlantic Fisheries Service, Marine Fish Division, Fisheries Research Branch, Scotia-Fundy Region, 4 pp .

A total of 4,323 haddock stomachs were collected for feeding studies during 1982 and 1983 seasonal groundfish surveys as well as on dedicated 1983 Fisheries Ecology Program research surveys. The main purpose of the Fisheries Ecology Program (1983-1985) was to determine the distribution of adult and juvenile haddock in NAFO division 4X and the variance in fish density within and between established groundfish survey strata. In 1982, a total of 1,877 haddock stomachs were collected in 4X and 97 in 4W in all seasons during surveys HAM1982072 (16-24 Mar groundfish survey), HAM1982076 (10-26 May silver hake survey), HAM1982080 (9-19 Jul groundfish survey), and HAM1982085 (12-26 Oct groundfish survey). In 1983, a total of 2,446 haddock stomachs were collected in 4X in all seasons during surveys HAM1983088 (6-11 Jan FEP survey), HAM1983089 (12-18 Jan FEP survey), HAM1983095 (5-15 Apr groundfish survey), NED1983010 (25 May-4 Jun FEP survey), and NED1983015 (30 Aug-9 Sep FEP survey).

### 3.1.2.3 Pollock surveys: POK (1983-1988)

Original investigators: Jacquie McGlade, Diane Beanlands, Chris Annand
Received from: Diane Beanlands
Current custodian: Diane Beanlands
Received format: hard copy
Current status: Excel, Oracle tables (stomach database)
Reference(s): Annand, C. 1987. Cruise Report: Alfred Needler - N082. Department of Fisheries and Oceans, 13 pp .
McGlade, J. 1986. Cruise Report: Lady Hammond - H147. Department of Fisheries and Oceans, Atlantic Fisheries Service, Marine Fish Division, Fisheries Research Branch, Scotia-Fundy Region, 5 pp .

The purpose of these stratified random surveys was to determine the distribution and relative abundance of pollock and to investigate factors that influence these patterns. Stomachs were collected from a number of species but most were from pollock (Table 15). Data from the following pollock cruises were located:

No stomach data in:
P285: 3-7 Mar 1983. Emerald Bank and 4X; haddock stomachs were sampled but data were not located.
RE01: Inshore pollock survey. No stomach content data.
H065: 13-22 Oct 1981. Fall groundfish inventory. No stomach content data.
H068: 1-5 Dec 1981. No stomach content data.
H087: 15 Nov-10 Dec 1982. No stomach data.
H151: 3-9 Feb 1986. No stomach content data.
N052: 23-25 Sep 1985. Cruise aborted early due to mechanical problems. No stomach content data.
N062: May 1986. Lobster survey.
N130: Dogfish stomach content data.
Stomach data in:
H110: 28 Nov-8 Dec 1983. Up to 100 pollock stomachs per set were collected in 4VWX and 5 Yd based on $3-\mathrm{cm}$ length groups and placed in nylon stockings into buckets of $10 \%$ buffered formalin. Stomach contents descriptions for the 232 collected are not very detailed.
H129: 22 Nov-10 Dec 1984. Subsampled 50 pollock, 1 per 1-cm length group per set for a total of 187 samples. Stomachs were stored in nylon stockings in $10 \%$ formalin. Stomachs (743) were also collected from white hake for an ongoing feeding study for the Gulf Region. There may be some mix up in numbers with cruise H110. Data include fish number, content weight, stomach fullness, content id (count, length, and/or weight)
H147: 4-13 Dec 1985. Types and numbers of prey species were identified in pollock and dogfish stomachs (no weights). Some data on cod was also collected.
N082: 1-12 Jun 1987. No mention of stomach collection in cruise report. Only 8 empty stomachs in database.
N103: 30 May-10 June 1988. About 250 pollock stomach contents were examined at sea for gross analysis only.

Table 15. Stomachs collected during 1983-1988 Pollock surveys.

### 3.1.3 Other Data Available

The following is a list of other data that have already been collected, some of which is available for editing and entry into stomach database and some of which is still in the hands of the custodians.

### 3.1.3.1 Groundfish Port Sampling: GPS (2001)

Original investigator: Peter Comeau
Received from: FSRS
Current custodian: Peter Comeau
Received format: Oracle
Current status: Oracle tables (stomach database edit mode)
Reference(s): none
About 600 cod and haddock stomachs were collected from commercial fish landings from the Scotian Shelf and Bay of Fundy during groundfish port sampling by request from the CDEENA project.

### 3.1.3.2 Commercial Fishing: CMF (2001)

Original investigator: MFD
Received from: Commercial fishery
Current custodian: MFD
Received format: Oracle
Current status: Oracle tables (stomach database edit mode), ISDB
Reference(s): none
Longhorn sculpin stomachs ( 175 samples) were collected from six commercial fishing trips by Lady Ella II and Vera \& Sisters for bait in St. Mary's Bay in 2001 (trips: J01-0106C, J01-0106C, J01-0112B, J01-0115E, J01-0117E, J01-0123B).

### 3.1.3.3 Silver Hake Survey Data: SHS (1981-1986)

Original investigator: Don Waldron
Received from: Cynthia Bourbonnais
Current custodian: Wayne Stobo
Received format: ASCII files on Emerald
Current status: Excel, Oracle tables (stomach database edit mode)
Reference(s): Waldron, D. E. (1988)
West, J. 2001. Retrieval of 1981-1985 fish stomach content data. Unpublished report.
West, J. 2001. Restoration of archival fish diet data from 1981-1985. Unpublished report.

Silver hake and other groundfish stomachs were collected during research surveys and commercial fishing trips from 1981 to 1986 for a study of silver hake predation and impacts on gadids as wells as cannibalism. The data compiled for the stomach database consists of 4,559 stomachs of which

2,674 are from silver hake and 1,251 are from cod. The files have been archived on Emerald (accounts EMF0701, EMF0703, EMF0702) and processed into Excel format. These data required a fair amount of reworking to get them to the format of the database. The data set as received by the authors contained numerous duplicate entries with different fish identification formats. The data has been entered into the database edit tables, however many errors may still exist due to errors in the original data or misinterpretation of the original data format.

### 3.1.3.4 Swordfish Data: SW (1980)

Original investigator: Julie Porter
Received from: Julie Porter
Current custodian: John Neilson
Received format: Excel
Current status: Excel, ready for database
Reference(s): none
In 1980, 197 swordfish stomachs (with contents) were collected and analysed during industry longline surveys. The survey ran from August to September and sampled fish from Cape Hatteras, Georges Bank, the Scotian Shelf, and the Grand Banks. Bait was included in the stomach contents because it was not possible to distinguish it from other prey. The data have been keypunched from contract report \#07SC.FP 706-1-C033 into an Excel spreadsheet. These are ready to be added to the stomach database.

### 3.1.3.5 Large Pelagics (2001)

Original investigator: steering committee for Central North Atlantic Bluefin Tuna Research
Current custodian: steering committee for Central North Atlantic Bluefin Tuna Research (DFO contact: John Neilson)
Current status: Access
Reference(s): none
Stomach samples were collected from swordfish and various tuna species during the 2001 Canadian North Atlantic Bluefin Tuna Survey in July. This survey extended from the Scotian Shelf to the mid-Atlantic ridge. These data are not currently available to DFO.

### 3.1.3.6 Christina Semeniuk's dogfish data (1997-1998)

Original investigator: Christina Semeniuk, Thomas Hurlbut
Current custodian: Christina Semeniuk
Current status: Excel, needs formatting for database
Reference(s): Semeniuk. C. and T. Hurlbut. 1998. Management and perceptions of spiny dogfish in Atlantic Canada. The IUCN/SSC Shark Specialist Group, Shark News 12: November 1998, http://www.flmnh.ufl.edu/fish/Organizations/SSG/sharknews/sn12/shark12news15.htm.

Spiny dogfish stomach data ( 313 samples) were collected in the Southern Gulf of St. Lawrence and on the Scotian Shelf in September 1997 and July and September 1998 on 4TVWX groundfish surveys for Christina Semeniuk's undergraduate thesis at Concordia University supervised by Dr. James Grant (Semeniuk and Hurlbut 1998). The study addresses the debate on predation impacts of dogfish on groundfish species.

### 3.1.3.7 Commercial Shark (1999-2001)

Original investigator: Steven Campana
Received from: Steven Campana
Current custodian: Steven Campana
Received format: Excel
Current status: Excel, needs formatting
Reference(s): Joyce et al. (2002)
Over 800 Porbeagle shark stomachs were collected and analysed during Canadian commercial longline fishing activities and a US National Marine Fisheries Service scientific survey from 1999 to 2001 (Joyce et al. 2002). The area sampled extends from the Grand Banks to the Gulf of St. Lawrence to the Gulf of Maine.

### 3.1.3.8 Recreational Shark Fishing (1999-2001)

Original investigator: Steven Campana, Meghan McCord
Current custodian: Steven Campana
Current status: unknown
Reference(s): McCord and Campana (In press)
During 1999-2001, 665 blue shark stomachs were examined in the Northwest Atlantic from recreational rod and reel fishing tournaments for a study on dietary differences based on sex, maturity and location (McCord and Campana, In press).

### 3.1.3.9 Juvenile Haddock Survey (1989)

Original investigator: Jeff McRuer
Current custodian: Ken Frank
Current status: Excel, not currently available to MFD
Reference(s): McRuer, J. 1989. Cruise Report: Alfred Needler - N121. Department of Fisheries and Oceans, Biological Sciences Branch, Science Sector, Marine Fish Division, ScotiaFundy Region, 4 pp .

In May 1989, 300 juvenile haddock stomachs were collected from Southwest Nova during research survey N121. The purpose of this cruise was to assess the abundance of juvenile haddock in NAFO division 4 X and to establish the most appropriate sampling time, technique and location for future surveys. A subsample of about 530 juvenile age- $1+$ haddock were retained in $4 \%$ buffered formalin and transferred to alcohol for gut analysis and otolith
extraction. Another 400 samples of other species were retained, however it is not known whether stomachs were analysed.

### 3.1.3.10 Dogfish Data (1985)

Original investigator: C. Annand, R. Mahon
Current custodian: Tim Lambert
Current status: hard copy only
Reference(s): J.D. Neilson. 1985. Cruise Report: Alfred Needler - N047. DFO, Atlantic Fisheries Service, Marine Fish Division, Fisheries Research Branch, Scotia-Fundy Region, 4 pp.
R.I. Perry. 1985. Cruise Report: Lady Hammond - H138. DFO, Atlantic Fisheries Service, Marine Fish Division, Fisheries Research Branch, Scotia-Fundy Region, 4 pp.
S.J. Smith and P. Koeller. 1985. Cruise Report: alfred Needler - N048-49. DFO, Atlantic Fisheries Service, Marine Fish Division, Fisheries Research Branch, Scotia-Fundy Region, 4 pp.

Dogfish stomachs were collected during industry trips in the fall of 1985. In June and July 1985, 150 stomachs were collected during research surveys N047, N048, and H138. The stomach contents data are not very detailed.

### 3.1.3.11 Mackerel Diet Data (1962-1974, 1976)

An effort was made to recover the mackerel diet analysed in MacKay (1979) in which inshore commercial fishery and research cruise data from 1962-1974 were compiled from the Atlantic coast of Nova Scotia and the Gulf of St. Lawrence. Over 9,600 fish were measured but it is not clear if stomachs were collected from all of these. Kulka and Stobo (1981) examined 111 silver hake stomachs from the Scotian Shelf, Georges Bank, and Nantucket Shoals, 199 mackerel from the Scotian Shelf, and 42 mackerel from Cape Cod in 1976. However, neither data set could be located.

### 3.1.3.12 4Vn Sentinel Survey (1995-2001)

Original investigator: Tim Lambert
Current custodian: Mark Showell
Current status: Quattro Pro, ISDB
Reference(s): none
About 30,000 cod stomachs were collected and examined during the 4 Vn sentinel surveys. These data are not very detailed and do not have weights for most of the prey items, thus they may not be useful for the stomach database.

### 3.1.3.13 Data Summary

An overall summary of data already in and for the stomach database is given in Table 16. Listings for which status is complete are already in the database. Data that are entered but still need some editing are in edit mode. Incomplete data need to be processed to conform to the format of the database and unavailable data have not been given to the custodians of the stomach database. Some of the samples have no location information available thus the area collected is unknown. The location of the actual data and the format saved in are given. The most common species collected in each survey or study are also listed.

Table 16. Summary of data already in or gathered for the stomach database. Some data are not yet available to the custodians of the stomach database. Stomachs in boldface with status complete are already in production mode within the database. Data in edit mode have been entered but need to be checked for errors. Incomplete data need processing. The most common species from which stomachs were taken are listed as common predator species.

### 3.2 Consumption and Diet Estimation

We present summary results on consumption and diet estimation for fish sampled during 4 VsW groundfish summer (July) surveys. An example of the process used to determine population level average daily consumption was taken from cod sampled on mission NED2000966, set number 48 in the year 2000 winter survey. This example is taken from the winter survey because of its smaller sample size for cod. The sequence of SQL scripts as described in Appendix IV produces eleven intermediate tables to get to the final consumption results. This code could use some refinement to make it more concise and to remove extraneous steps or information.

The first table 'gssto_work' (Table 17) is compiled from all three stomach database tables and information such as location and date from the groundfish survey (GS) database. It contains all the necessary data for further calculations. The next step groups prey items (sums prey weights) by the ecopath model groupings (ecocodes, see Table 2) and produces the table 'gscross' with one row entry for each stomach collected (Table 18). Table 19, 'gsconsum_calc', has the fish length code added for the $5-\mathrm{cm}$ length groups, ecocodes replaced by ecogroup names, and consumption (g/d) by each fish calculated using the dos Santos and Jobling (1995) model. The table 'gsconsumraw' (Table 20) then contains the average consumption, fish length, and fish weight of each predator species and $5-\mathrm{cm}$ fish length group within a set for non-empty stomachs. 'Incl_empty gsconsumraw' (Table 21) has these same values adjusted to include empty and everted stomachs some of which were collected and some were only recorded in the GS database. Contents for everted stomachs were averaged from contents of stomachs from the same species and fish length collected in the same NAFO division, season and year.

Table 17. Subsample of table 'gssto_work' of data taken from the stomach and groundfish survey databases that are required for consumption calculations. These data are only for cod sampled from set 48 of mission NED2000966.

The average ration table 'avgr' (Table 22) is similar to 'incl empty gsconsumraw', however the columns of prey items have been converted back to rows. Zero values for prey types not eaten are included for calculations in later steps. The next step averages rations across sets resulting in average rations by series (season), year, and stratum. This table called 'avg_prey_ration' is not shown here since only a single set is being demonstrated. The standardised number of fish caught per $5-\mathrm{cm}$ length class as determined by corrections for differences in area coverage of sets were obtained from oracle database NWAGS.gsd5if $m v$ and arranged by series, year, and stratum in table 'avg_no_pred' (Table 23). This number of fish per length is used to calculate total rations per length class as shown in table 'tot_no_pred rrn' for $53-\mathrm{cm}$ cod from this set that is in stratum 404 (Table 24). The final consumption calculation is to determine the total ration for each NAFO division in table 'tot unit_avgrtn' (Table 25). The ration for each stratum is calculated by multiplying the ration per net tow by the number of tows needed to cover the stratum (ration / no. tows * area / tow length * trawl width). These strata totals are summed for each NAFO area. This table also includes total standardised numbers of fish at length from 'totnopredatlgth' (Table 26) extrapolated for the NAFO area. The total number and total ration are then used to calculate an average ration. The final results table 'FINAL_avg_rtn' lists the average rations for prey types eaten and includes empty/everted stomachs as well as the number of stomachs collected and the total number of stomachs observed (from 'nopred_all', Table 27) by series, year, species and fish length group (Table 28).

Table 29 shows average daily consumption (g/d) by fish for each fish length group and species surveyed for 1999 and 2000 pooled together. These values were calculated using the gastric evacuation model and include interpolated rations for fish lengths surveyed but not collected. Consumption generally increases with predator size. Monkfish, pollock and cod consume the most food in a day on average. Table 30 shows these results as annual ( $\mathrm{g} / \mathrm{y}$ ) instead of daily consumption.

It is be expected that consumption would increase with size, however there are samples missing for some fish lengths in Tables 29 and 30 . For example, cod of length 73 cm appear to be eating less than $68-\mathrm{cm}$ cod and no value is available for $78-\mathrm{cm}$ cod. Plots of consumption by individual fish (cod, haddock, and pollock) against body weight (Figure 10) show an increase in food intake with increasing fish size. The spread in the data at larger sizes shows the variation in consumption. This may be dependent on time of day and stomach fullness at collection.

The average daily consumption of each prey type by each predator species is shown in Table 31 and the same results are given as proportions of each prey type eaten in Table 32. These values were calculated with the gastric evacuation model, pooled across 1999-2000 and averaged across all fish lengths.

Diet estimation from actual stomach contents without the gastric evacuation model were compared to consumption proportions from the model for 1999 and 2000 separately and pooled together for cod (Table 33, Table 34), haddock (Table 35, Table 36) and pollock (Table 37, Table 38). The results are given by fish length and prey type. Cod diets appear to shift from predominantly shrimps and large zooplankton to sandlance with increasing cod size with or without the model.

The gastric evacuation model uses larger half-life parameters (see Table 3) for harder to digest prey items like small pelagics, shrimps and crabs and smaller half-lives for juvenile cod, juvenile silver hake, American plaice, polychaetes, other benthic invertebrates, and zooplankton. A larger half-life value accounts for slower digestion and thus the model suggests that these prey items were consumed less relative to the other items present in the stomach and vice versa for small half-life values. This is evident in the cod pie chart results pooled across 1999-2000 where for example the proportions of small pelagics and shrimps in the stomach contents are reduced with the consumption model and large zooplankton are increased (Figure 11).

- Ipoui

Figure 10. Daily consumption per fish plotted against body weight of cod, haddock, and pollock. The linear regression is shown as a solid line. The dashed line represents approximate maximum consumption by body weight.

## CONCLUSION

The compilation of data from various stomach collection programs resulted in creating a sizeable source for present and future research. Although data is lacking from the 1980s, hopefully new data will be added to facilitate study of longer time series' of data. The reformatting of various types of data is a time consuming process and unfortunately some information was lost or missing along the way. Requests should be made to stomach data collectors to gather all the useful information even if it is not required for the collector's own research. Care should also be taken in the data collection and logging process to reduce errors as much as possible. The data in this database should not be assumed to be fully accurate. The data has been checked for errors, but some problems may have been missed. This document should provide enough information for future managers and users of the stomach database.

## 4 ACKNOWLEDGEMENTS

The authors wish to acknowledge the financial support of the Comparative Dynamics of Exploited Ecosystems in the Northwest Atlantic (CDEENA) project the BIO Data Rescue "Hudson Fund". In addition, the support and assistance provided by the many data custodians named in this document and other DFO staff was invaluable in bringing together the abundance of stomach data and information that already existed. In particular, we would like to thank Pierre Brien and Bob Branton for setting up the database and Virtual Data Centre applications. Recovery of pre-1970's data was accomplished with the assistance of Kees Zwanenburg, Carl MacDonald, and Shelley Bond.

## APPENDIX I: STOMACH SAMPLING REQUEST

## Stomach Sampling Request for the July Groundfish Survey, July 2000

As part of the focus on ecosystem models this year we are requesting that stomach samples be collected on a length-stratified basis for the following list of species. If sampling cannot be completed on every station due to time constraints it is desired that samples include a good geographic coverage and good predator size coverage, including juveniles, if caught.

|  | Top Priority |  | Less Priority |
| :---: | :---: | :---: | :---: |
| species code | common name | species code | common name |
| 10 | Cod (Atlantic) | 13 | Red Hake |
| 11 | Haddock | 14 | Silver Hake |
| 12 | White Hake | 15 | Cusk |
| 16 | Pollock | 30 | Halibut (Atlantic) |
| 23 | Redfish | 31 | Greenland Halibut |
| 40 | American Plaice | 41 | Witch Flounder |
| 60 | Herring (Atlantic) | 42 | Yellowtail Flounder |
| 201 | Thorny Skate | 43 | Winter Flounder |
| 204 | Winter Skate | 50 | Striped Atlantic Wolffish |
| 220 | Spiny Dogfish | 51 | Spotted wolffish |
| 300 | Longhorn Sculpin | 52 | Northern wolffish |
| 320 | Sea Raven | 64 | Capelin |
| 610 | Sandlance | 70 | Mackerel (Atlantic) |
| 647 | Vahls Eelpout | 160 | Argentine |
|  |  | 202 | Smooth skate |
|  |  | 400 | Monkfish |
|  |  | 501 | Lumpfish |
|  |  | 640 | Ocean pout |

Individual Fish Data: Prior to the stomach's removal from the fish, the bag label should be completed including:

Cruise number
Set number
MFD research code (e.g. '10' for cod)
Fish number
Information should be clearly written in permanent ink on the bag or in pencil on a piece of waterproof paper placed in the bag.

Stomach Fullness Index: As part of the detailed sampling requirements for the selected species, a stomach sample will be required as follows:

For each required sample, determine the stomach fullness index using the following scale. It is
realised that there is a degree of judgement required to assessing the fullness.

```
0 - empty - no food contents
1 - less than }1/4\mathrm{ full
2-1/4 to }1/2\mathrm{ full
3-1/2 to 3/4 full
```

based on visual assessment of contents with respect to estimated capacity

```
4-3/4 full to full J
5 - everted - stomach displaced into oesophagus and/or mouth
6 - regurgitated - stomach flabby and thin, may have food remains in mouth
```

Stomach excision: For stomachs with contents, index 1-4, push any contents from the oesophagus back into the stomach. Then make a cut at the posterior end of the stomach at the pyloric caeca. Cut the oesophagus as far forward as possible. Place the stomach and contents in a pre-labelled Whirl-Pak bag or 8-lb poly bag. Carefully slit the stomach wall once the stomach has been placed in the bag. This will allow the brine into the stomach stopping digestion. Add brine* to the bag to cover the contents and seal it. Place bags in totes in the freezer.

Data recording: To generate a fish number for species where no otolith is taken, the code ' 2 ' will be entered into the age material field. When otoliths and the stomach are both taken the code ' 1 ', which is usually used in the age material field, will be used. The stomach fullness code will be entered in the Remarks field, preceded by an ' S ' for stomach (e.g. a full stomach would have ' S 4 ' as a remark).

* Concentrated brine is made by adding 2 double handfuls of salt to a 10 -litre bucket of seawater. After stirring well, there should still be some salt on the bottom. Concentrated brine should not freeze solid. When in doubt, add more salt.
APPENDIX II: DATA SHEET
STOMACH ANALYSIS DATA SHEET Trip: $\quad$
Date Caught:
Fish \#:
Stomach Total Wt.:
Technician:

| Item | Species |
| :---: | :---: |
|  |  |
|  |  |
|  |  |
|  |  |
|  |  |
|  |  |
|  |  |
|  |  |
|  |  |

Fullness codes: $0=$ empty, $1=25 \%, 2=50 \%, 3=75 \%, 4=100 \%, 5=$ everted, $6=$ regurgitated Item condition: $1=$ great condition, $2=$ good condition, $3=$ very digested, $4=$ unidentifiable

## APPENDIX III: SAMPLE PROCESSING PROTOCOLS

## Stomach Analysis

Working in pairs makes the analysis of the stomach contents more organised and can facilitate species identification.

Technician1:

- the label data from the bag containing the thawed predator stomach and contents is recorded on the data sheet
- the stomach contents are removed by emptying the bag onto a fine mesh strainer and the bag is gently rinsed to ensure no loss of contents
- the contents are emptied onto a small plastic tray along with the empty stomach
- the contents and emptied stomach are weighed and the weight recorded on the data sheet (to 0.01 g .)
- the empty stomach is weighed separately and the weight recorded on the data sheet. The empty stomach is then placed back into its bag and set aside
- the tray and the stomach contents are passed onto the second technician

Technician 2:

- each item on the tray is identified, if possible, and the weight and length of the item are recorded on the data sheet, as well as the quantity of the item
- otoliths are used as further identification of fish species when the scales, skin and flesh is too digested for a positive ID
- keys are used for consultation as well as the help of the other technician

If there is uncertainty about the species or items are too digested, a detailed description of what is seen should be recorded in the 'Remarks' section of the data sheet. Species codes should be used when listing species in the general and detailed category for easier accessibility in the database.
N.B.: appropriate safety procedures must be strictly followed for samples preserved in formaldehyde.
Technicians must wear gloves and goggles at all times. To process the sample, it is first removed from the formaldehyde and rinsed for several minutes over a screen. The waste formaldehyde is collected and stored in a container for later disposal. The sorting, as outlined above, is then performed under a fume hood. After processing is complete, the stomach and its contents are stored for proper disposal.

## Identification level

The following is a list of common prey 'items' found in fish stomachs form the Scotia-Fundy region and the taxonomic level to which they are normally classified.

## PREYITEM

Anthozoa - class
Cnidaria - class
Crustacean - species for commercially important or abundant specimens, order otherwise
Crustacean Eggs - order
Ctenophore - phylum
Decapoda larvae - order
Echinoderm - class
Fish - species
Fish eggs - species
Invertebrate eggs - phylum
Mollusc - species for the commercially important or abundant species, class otherwise
Mollusc Eggs - class
Nematode - class
Polychaete larvae - class
Protochordata sp - class
Platyhelminthes - phylum
Polychaete- family
Porifera - phylum
Pycnogonida - class
Seaweed - phylum
Urochordata - class

## Identification Keys

The keys commonly used by the FSRS technicians in identifying prey items include:

- Keys to Marine Invertebrates of the Woods Hole Region
- Keys to the Fauna and Flora of the Minas Basin
- Peterson's Field Guide
- Scott and Scott

## Special Cases

The following prey items are exceptions to the naming practices outlined above:

- Indigestible remains: Remains (e.g. mollusc remains or fish remains) is used as the species name for indigestible parts such as shells, squid beaks, otoliths, and other hard materials.
- Eggs and larvae: Eggs and larvae should be identified as such in the item and species fields rather than simply identifying them by species, e.g. Fish eggs, Skate Purse instead of Fish, Skate.
- Bait: Bait should be identified as bait in the item field and type of bait in the species field, e.g. Bait, Bait Mackerel.
- Garbage: Anthropogenic garbage should be identified simply as inorganic debris. Any details can be added in the remarks column.
- Unidentified materials: Terms such as unidentified or organic debris should be avoided. Rather, be specific such as unidentified fish or unidentified invertebrates. Details should be added to the remarks column whenever possible.
- Shrimp like: This term is confusing and should be avoided. Enter as shrimp or krill if not easily recognisable as Pandalus sp .
- Shrimp: Often used when the item is very digested and is identifiable only as a shrimp species, which could include pandalids.

## APPENDIX IV: CONSUMPTION SQL PROCEDURE

The individual stomach data were used to calculate population level consumption estimates using various SQL scripts. The general process is:

The following text describes and details the SQL code and Oracle table creation process that culminates with a final table of consumption results (average population level rations per length class) called 'FINAL_avgrtn'. The steps are numerous and fairly complex. The subsequent flowcharts connect the codes, tables and datasets to assist in visualization of the process.
A) empty_stoms.sql and s5_stoms.sql - to pull out empty and everted (S5) stomachs from both GS and SD databases since most of these were not actually collected ( $N B$ : some empties were collected). Also, empties must be included in consumption calculations.
B) consumption gs ML.sql - to get consumption at set level using gastric evacuation model

Creates tables:
. gssto_work
2. gscross
3. gsconsum_calc
4. gsconsumraw
5. non5fsh gsconsum
6. allfsh_gsconsum
7. incl_empty_gsconsumraw

1. GSSTO_WORK with mission, setno, strat, year, seas, region, bottom_temperature, spec, fshno, fwt, flen, preyspec, preyspeccd, pwt, pnum, plen from groundfish.sdview1 and groundfish.gsinf where fullness is $1,2,3$ or 4 , datasource is GS, fish length is not null and stratum not 494 or 495 (upper Bay of Fundy). Add columns ecopred, ecoprey from the ecopathcode table. Also add temperature from gstemperature which was created from groundfish.gshyd.
2. GSCROSS with mission, setno, strat, region, year, seas, bottom temperature, spec, ecopred, fshno, flen, fwt and p4, p5 etc. This has one row entry for each stomach collected. Each p4, p5 etc. column has the sum of the species prey weights that correspond to each of these ecopathcode prey categories. Add column "total" for weight of material in stomach and "total_id" for material of only identified origin (not p100, p200, p300).
3. GSCONSUM_CALC with mission, setno, strat, region, year, seas, temp, spec, ecopred, fshno, flen, flen_code ( $5 *$ ceil(flen $/ 5$ ) $-2,5 \mathrm{~cm}$ length groups), fwt, cod, j_cod etc. The columns cod, $j$ cod etc. have consumption (g/day) calculated with equation from dos Santos and Jobling (1995). Get a row entry for each stomach. Only calculated when bottom temperature is not null. (Lei Harris had calculated only where not all stomach contents are unidentified, but this has been changed).
4. GSCONSUMRAW with mission, year, region, strat, setno, seas, spec, sample, flen_code, avg_flen, avgcod, avgj_cod, etc. This averages consumption for each predator species and fish length within a set -calculate consumption on a set by set basis regardless of how many fish sampled, thus each set waited equally. Only for NON-EMPTY stomachs.
5. NON5FSH_GSCONSUM. Adds empty stomachs from table empty_stoms (created in code empty_stoms.sql from GS and stomach databases) to gsconsum_calc.
6. ALLFSH_GSCONSUM. Adds everted (S5) stomachs from table s5_stoms (created in code s5_stoms.sql from GS and stomach databases) to gsconsum_calc. Contents for everted stomachs were averaged from contents of stomachs from the same species and fish length collected in the same NAFO division, season and year.
7. INCL_EMPTY_GSCONSUMRAW. Same as gsconsumraw but with empty and everted stomachs included.

Now use code avgr0_ML.sql and incl_empty_gsconsumraw to create table AVGR0 that has the columns of prey consumption expanded into rows. Include all zeros to properly calculate average consumption.
The AVGR0 table is used in weighted by number*.sql to calculate population level consumption.
C) weighted by number seqtl_0_ML.sql - to get population level rations

Creates views or tables:

1. avg_prey_ration - The average prey rations for each predator species length class by series, year and stratum. First create avg_prey_ration0 with all zero values included from the AVGR0 table. Average ration for each prey type is calculated based on a single average ration value (in the AVGR0 table) calculated for each set. Therefore not a weighted average based on how many fish caught per set.
2. avg_no_pred - The average number of predator species at length (standardised count at 5 cm length classes from NWAGS.gsd5lf_mv) by series, year and stratum for a selected area or unit and year range.
3. tot_no_pred_rtn - The total number of predators at length and the total ration of prey by series, year and stratum. The standardised count at length is summed across sets for each prey type. This only gives the total number of fish eating that prey type.
4. tot_unit_avgrtn - The total rations for the area or unit. Stratum totals are calculated by multiplying the total ration per net tow with the number of tows needed to cover the stratum
(ration / no. tows * area / tow length * trawl width). Strata totals are summed to cover the whole area or unit. [Note: tow length $=1.75 \mathrm{~nm}$, trawl width $=41 \mathrm{ft}, 1 \mathrm{~nm}=6080.2 \mathrm{ft}$ ]
D) consump count at length.sql - To get total standardised population count at length.
5. totnopredatlgth - Calculate standardised total number of fish at length (totnofl) within each stratum and then sum these up to cover the whole area or unit. These numbers are used to calculate average ration per fish using the total rations in table tot_unit_avgrtn above.
E) consump pred count at length.sql - To determine the actual number of stomachs collected per set as table nopred.
F) Consump combine tables.sql - Takes series, year, predator, fish length, prey, total ration from table tot_unit_avgrtn, number of stomachs sampled per fish length (obs) from table nopred, and total number of fish in population per fish length (totnofl) from table totnopredatlgth and combines them into a single table called gsconsfinal. Zeros are added for fish lengths for which only empty stomachs were examined from table gsconszeros to produce a final table called FINAL_avgrtn. Another table must be produced from using totnopredatlgth to fill in rations for fish lengths sampled in the groundfish survey that had no stomachs collected.

The last step is to import the results into Excel and incorporate the missing fish lengths. Then calculate rations for the missing fish lengths based on rations for fish lengths above and below the blank ones.

## Consumption Calculation Overview

Calculate consumption per fish length and set (script: consumption gs ML.sql)

Count total number of stomachs sampled (script: consump count at length.sql)

Count number of stomachs collected (script: consump pred count at length.sql)

Calculate total population level consumption per NAFO division (script: weighted by number seqt1 0 _ML.sq1)

Consolidate results from sub-processes (script: consump combine tables.sql)

## APPENDIX V: CONSUMPTION SQL SCRIPT

SQL script for consumption calculation for groundfish survey stomach data

## Consumption calculation

```
REM "consumption gs ML.sql"
REM original created by Lei Harris June 28th 2001, edited Dec 20th 2001
REM calculate diet species by species rather than by ecopath code
PEM excluded upper bay of fundy - not in strat 494,495
REM changes made Aug-Sep 2002 by Marjo Laurinolli
REM consumption calculations for GS surveys only
REM no calculation of consumption if no bottom_temperature
REM include empty stomachs in the calculations
REM empty and s5 (everted) stomachs incorporated from GS and SD tables with union command - checked
for duplicates
REM see empty_stoms.sql land s5_stoms.sql for empty and s5 tables
REM }16\mathrm{ entries missing that had duplicate mission, setno, spec, fshno (blank), flen, fwt in empties-
minus command removed them
REM compare to non-gastric evacuation results by using code "preywts without ge.sql"
REM season and year info incorporated here is not used in later steps, taken from
mflib.gs_survey_list instead
REM nafo also taken later from mflib.gsmgt
-- get bottom temperatures

## Convert columns to rows

REM "avgro_ML.sqi"
REM this table was created August 102001 by Lei Harris
REM in order to rationalise the table gsconsumraw_test. (ie. turn columns of prey into rows -ML)
REm It is to be used when extrapolating average consumption by spec, flen_code, setno to get total
consumption.
REM used by M Laurinolli 30 Sep 2002 (changed gsconsumraw_test to incl_empty_gsconsumraw test)
REM revised 01 Nov 2002 to include zeros and include number of samples
REM average consumption per set
drop table avgro;
create table AVGRO (
mission varchar (15),
setno number(3)
spec number(4),
flen_code number(3),
prey number(3),
sample number(3),
avgr number(12,6));

REM When include flens surveyed from gs, cons calculated from other flens for
REM those flens without prey items.
insert into avgro select mission, setno, spec, flen_code, 4, sample, avgcod from
incl_empty_gsconsumraw_test ;
insert into avgro select mission, setno, spec, flen_code, 5, sample, avgj_cod from
incl_empty_gsconsumraw_test ;
insert into avgro select mission, setno, spec, flen_code, 6, sample, avgshake from
incl_empty_gsconsumraw_test ;
insērt into avgro selē̄t mission, setno, spec, flen_code, 7, sample, avgj_shake from
incl_empty_gsconsumraw_test ;
insert into avgro select mission, setno, spec, flen_code, 8, sample, avghaddock from
incl_empty_gsconsumraw_test ;
inser̄t into avgro selē̄t mission, setno, spec, flen_code, 9, sample, avgam_plaice from
incl_empty_gsconsumraw_test ;
insert into avgro select mission, setno, spec, flen_code, 10 , sample, avghalibuts from
incl_empty_gsconsumraw_test ;
