#### Abstract

Haggarty, D.R., and King, J.R. 2005. Hook and line survey of Lingcod (Ophiodon elongatus) and Rockfish (Sebastes spp.) in northern Strait of Georgia (statistical areas 13, 14, 15 and 16) June 14-July 9, 2004. Can. Tech. Rep. Fish. Aquat. Sci. 2590: 57p.

Research fishing methods using hook and line gear were developed in 1984 and 1985 to assess near shore reef fish abundance in the Strait of Georgia. Several hook and line surveys for rockfishes and lingcod were subsequently completed between 1985 and 1993 using these methods at study sites in Statistical Areas (SA) 13, 15 and 16. From June 14July 9, 2004, we revisited these study sites and fished using similar gear and methodology. We compare our catch per unit of effort (CPUE) data to historical CPUE in SA 13 with 1986, 1987 and 1988; in SA 15 with 1985; and in SA 16 with 1985 and 1986. In addition, we surveyed sites in SA 14 and the shallow stratum of SA 17. Lingcod catch' rates have increased over time in SA 13 and 15 but not in SA 16. In SA 13, lingcod catch rates were greater than 1987 and 1988 but were not different from 1986. 2004 lingcod catch rates in SA 15 exceed 1985 catch rates. The size of male and female lingcod in SA 13, 16 and male lingcod in SA 15 also increased in 2004. SA 13, 15 and 16 had higher lingcod catch rates than SA 14 and 17. In SA 13, copper rockfish catch rates in the shallow stratum were significantly lower in 2004 and 1987 than in 1986 or 1988. Copper rockfish catches were uniformly low in the deep depth strata of SA 15 and 16 in all years. Quillback rockfish catch rates were lower in the shallow stratum in 2004 in SA 13 and 16. Quillback catch rates may be affected by a change in leader strength; however, we attempt to correct for any bias introduced by this change.

## RÉSUMÉ

Haggarty, D.R., and King, J.R. 2005. Hook and line survey of Lingcod (Ophiodon elongatus) and Rockfish (Sebastes spp.) in northern Strait of Georgia (statistical areas 13, 14, 15 and 16) June 14-July 9, 2004. Can. Tech. Rep. Fish. Aquat. Sci. 2590: 57p.

En 1984 et en 1985, des méthodes de pêche scientifique à la ligne ont été mises au point pour évaluer l'abondance des poissons de récifs côtiers dans le détroit de Georgia. De 1985 à 1993, plusieurs relevés des sébastes et de la morue-lingue ont été effectués selon ces méthodes à des stations situées dans les zones statistiques (ZS) 13,15 et $16 . \mathrm{Du}$ 14 juin au 9 juillet 2004, nous sommes retournés à ces stations et y avons pêché au moyen d'engins semblables et selon la même méthode. Nous comparons nos données de captures par unité d'effort (CPUE) à celles de 1986, de 1987 et de 1988 pour la ZS 13, à celles de 1985 pour la ZS 15 et à celles de 1985 et de 1986 pour la ZS 16. En outre, nous avons effectué des relevés à certains endroits de la ZS 14 et dans la strate peu profonde de la ZS 17. Les taux de capture de morues-lingues ont augmenté avec le temps dans les ZS 13 et 15, mais pas dans la ZS 16. Dans la ZS 13, les taux de capture de morues-lingues en 2004 étaient plus élevés qu'en 1987 et en 1988, mais ne différaient pas de ceux observés en 1986. Dans la ZS 15, les taux de capture des morues-lingues étaient plus élevés en 2004 qu'en 1985. La taille des morues-lingues mâles et femelles dans les ZS 13 et 16, ainsi que celle des morues-lingues mâles dans la ZS 15 ont augmenté en 2004. Les taux de capture des morues-lingues dans les ZS 13, 15 et 16 étaient plus élevés que dans les ZS 14 et 17. Dans la ZS 13, les taux de capture des sébastes cuivrés dans la strate peu profonde étaient significativement moins élevés en 2004 et en 1987 qu'en 1986 ou en 1988. Les captures de sébastes cuivrés étaient toujours faibles dans les strates profondes des ZS 15 et 16. Les taux de capture des sébastes à dos épineux étaient moins élevés en 2004 dans la strate peu profonde des ZS 13 et 16. La modification de la résistance des avançons utilisés pourrait avoir influé sur le taux de capture des sébastes à dos épineux, mais nous avons tenté de corriger le biais introduit par ce changement.

## INTRODUCTION

Lingcod (Ophiodon elongatus) populations in the Strait of Georgia appear to have been at a very low level of abundance for several decades (Richards and Hand 1989; King 2001). In response to conservation concerns, the commercial fishery was closed in 1990. The recreational fishery, prior to 2002, was subject to regulations including a winter nonretention period to protect nest guarding males, non-retention of fish less than 65 cm , a one per day bag limit, and an annual catch limit of 10 lingcod per year. In 2002, the recreational fishery was closed for the retention of lingcod as an additional measure to protect this stock (King and Surry 2000).

A stock assessment framework for lingcod recommended development of fishery independent sources of relative abundance to monitor changes in the Strait of Georgia lingcod population (King et al. 2003). One recommendation was to resume the hook and line surveys of nearshore reef fishes conducted in the Strait of Georgia in 1985, 1987-88 and 1993. In 1984 hook and line surveys were developed to estimate lingcod and rockfish catch per unit of effort (CPUE) and were then conducted in the Northern Strait of Georgia (Statistical Areas (SA) 13, 15 and 16) in 1985-1988 (Richards and Cass 1985, Richards et al. 1985, Richards and Cass 1987, Richard and Hand 1987). In SA 15 and 16, the survey area was divided into 1 minute latitude by 1 minute longitude blocks, and those blocks encompassing known lingcod fishing areas were identified (Richards et al. 1985). In SA 13, fishing sites were chosen from known areas of commercial fishing (Richards and Cass 1987). Sites in SA 13 were sampled in 1986, 1987, and 1988; SA 15 in 1985; and SA 16 in 1985 and 1986.

Between June 14 and July 9, 2004, we conducted a hook and line survey in SA 13, 15 and 16 , re-visiting the same sites sampled in previous years. In addition, we sampled five new sites in SA 14 and five sites in SA 17 that were sampled in the fall of 2003 (Haggarty and King 2004).

While the primary focus of this survey was to investigate the relative abundance of lingcod, other nearshore reef fishes such as rockfishes (Sebastes spp.), kelp greenling (Hexagrammos decagrammus), cabezon (Scorpaenichthys marmoratus) and spiny dogfish (Squalus acanthias) were caught in all survey years. The 2004 lingcod survey provides an index of relative abundance for copper rockfish (S. caurinus) and quillback rockfish (S. maliger) in addition to lingcod. Nearshore rockfish species in the Strait of Georgia have suffered serious declines in abundance (Yamanaka and Lacko, 2001). A rockfish conservation strategy that includes a reduction in fishing mortality, the implementation of rockfish protection areas, improved catch monitoring and stock assessment has been implemented.

## METHODS

The vessel used as a platform for fishing was a 6.7 m aluminium "Lifetimer" boat equipped with twin 115-horse power engines, a depth sounder, GPS, and laptop computer with the geographic positioning software "Nobeltech ${ }^{(8}$ " and the program "Tides and Currents®". Fishing was conducted using the handline survey methodology developed by Richards et al. (1985) and Richards and Cass (1985).The fishing crew consisted of four research personnel, with three or four people fishing at a time (depending on environmental conditions). We used Zebco® Rhino ${ }^{\circledR}$ rods with Rhino ${ }^{\circledR}$ RBCXL or Shakespeare ® Tidewater ${ }^{\circledR}$ 30LCL reels, rigged with $13.6 \mathrm{~kg}(30 \mathrm{lb})$ test mono-filament line and a $170 \mathrm{~g}(6 \mathrm{oz})$ mooching weight. Two single Mustad \#92553 size $3 / 0$ hooks with a 6 cm spacing were tied with $11 \mathrm{~kg}(25 \mathrm{lb})$ test mono-filament leader. We used 12 cm frozen herring as bait, hooked through the snout and just in front of the dorsal fin. Previous surveys used $9 \mathrm{~kg}(20 \mathrm{lb})$ test mono-filament with a $7 \mathrm{~kg}(15 \mathrm{lb})$ leader. We used stronger line for the leaders than previous surveys to minimize the loss of lingcod due to line breakage. To test for the effect of leader strength on catch rates, we fished with both the light ( 7 kg ) and heavy ( 11 kg ) leaders in SA 15 and 16 with one (randomly selected) fisher using the light ( 7 kg ) leader.

We revisited sample sites surveyed in SA 13 in 1986, 1987 and 1988; SA 15 in 1985; and SA 16 in 1985 and 1986 (Figures 1 and 2). All sites represented areas of presumed lingcod (age $2+$ ) and rockfish habitat. New sample sites were chosen in order to extend the spatial coverage of this survey into SA 14. We also revisited five sample sites in SA 17 that were sampled in the October 2003 hook and line survey (Haggarty and King 2004) in order to compare fall catch rates in SA 17 to SA sampled in the summer. Due to time constraints, only the shallow stratum was fished in SA 17. All sites consisted of rocky reefs of appropriate depths as indicated on nautical charts.

We sampled two depth strata per site ( $0-25 \mathrm{~m}, 26-50 \mathrm{~m}$ ). These are different strata than those used in previous surveys, and correspond to depth strata that were sampled in the 2003 survey of the southern Strait of Georgia (Haggarty and King 2004) as well as the 1993 survey of SA 18 and 19 (Yamanaka and Murrie 1995). Three depth strata were sampled in the previous surveys in SA 13, 15 and 16 (5-40 m, 41-70 m, and 71-100 m). We eliminated the deepest depth stratum to avoid yelloweye rockfish bycatch, and because lingcod catches declined with increasing depth in previous surveys (King et al. 2003). We used different, shallower depth strata ( $0-25 \mathrm{~m}, 26-50 \mathrm{~m}$ ) because lingcod, copper rockfish and quillback rockfish catch rates often vary between the $0-25 \mathrm{~m}$ and 26 50 m , and depth strata with a more narrow range should reduce overall variability of catch rates. In order to compare the 2004 data to previous surveys, fishing sets from the 1980s were re-classified into our depth strata using their modal depth, the depth at which most of the fishing occurred. Sets with modal depths exceeding 50 m and maximum depths exceeding 55 m were excluded from the analysis.

As in previous studies, fishing effort was defined as the total fishing time of all fishers. Each fisher kept track of fishing time, which represented the time the line was on or near
the bottom, using a digital stop watch strapped to the butt of the rod. Fishing time started when the fishing gear touched the bottom and stopped whenever a fish was hooked, there was a bite, the gear become fouled on the bottom, or the line was reeled in. Fishing effort on the light ( 7 kg ) leader was counted separately.

Each site and depth stratum was fished for a total of 30 minutes of bottom time. In SA 15 and 16 , the 30 minutes did not include time spent fishing with the light ( 7 kg ) leader. We adjusted our position within the site if no fish were caught within 5 minutes, if we felt we were no longer in appropriate lingcod habitat, or if we were no longer within the depth stratum. Variables recorded for each set included weather, tide, currents, sea state and the minimum, maximum and modal depths encountered. We stopped fishing if currents or wind were too strong for fishing to be effective.

A catch was recorded if a fish was brought to the surface and could be identified to species. Lingcod, rockfishes and kelp greenling were sampled for fork length (mm), -weight (g), sex, and stage of maturity. Fin rays of lingcod and otoliths of rockfishes were collected for age estimation. Fork or total length for other species was measured before releasing them. Lingcod stomach contents were identified to the lowest taxonomic group possible. Stomachs were examined while fish were still relatively fresh and the volume $\left(\mathrm{cm}^{3}\right)$ of primary, secondary and tertiary prey items were estimated using a graduated cylinder.

## Catch Per Unit of Effort Analyses

Catch per unit of effort (CPUE) was calculated as the number of fish per hour (fish/hr) for total fishes (all species together), lingcod, copper rockfish and quillback rockfish. Effort was the total fishing time of all fishers. CPUE and effort were counted separately for time spent fishing with the light leader, and fish caught on the light leader were not included in the calculation of the overall CPUE. CPUE was also calculated for total fishes and for lingcod for each fisher in order to investigate bias among fishers.

Difference among catch rates of each fisher was investigated using the Kruskal-Wallis test (non-parametric ANOVA). Differences in median CPUE and lingcod length between depth strata and statistical areas were tested with the Mann-Whitney test (non-parametric t-test, test statistic U ) and Kruskal-Wallis test (non-parametric ANOVA, test statistic H) respectively. CPUEs were compared between years by depth strata using the KruskalWallis test or Mann-Whitney test. Male and female lingcod lengths were compared using the Mann-Whitney test. Difference in lingcod length between depth stratum and among years was investigated with the Mann-Whitney or Kruskal Wallace test. When significant differences were obtained with the Kruskal-Wallis test, we used a comparison of mean ranks procedure to compare the individual mean ranks of the different groups and to identify subsets of similar mean ranks (Analytical Software, 2000). All analyses were performed using Statistix software (Analytical Software, 2000).

For SA 15 and 16, catch rates for the heavy ( 11 kg ) and light ( 7 kg ) leaders were compared using a two-tailed Wilcoxon signed rank test with continuity correction. We also compared the number of line breakages for each type of leader using the Chi-squared test with the Yates correction for continuity.

## RESULTS

We sampled thirty-five sites from June 14-July 9, 2004 (Figures 1 and 2). We fished for a total of 33.6 hours (bottom time) over the entire survey. Total fishing time in SA 13 was 11.2 hours; 11.9 hours in SA 14; and a total of 13.3 and 12.7 hours in SA 15 and 16 respectively. An additional 3.9 hours were accumulated in SA 17 (shallow stratum only). Location, depth, time and environmental data for each set are reported in Appendix Table 1: Appendix Table 2 presents the catch and effort data for each set including the effort by each fisher. Length, weight, sex and stage of maturity data for lingcod, copper rockfish, quillback rockfish and dogfish are presented in Appendix Tables 3-6. Biological data from all other species are in Appendix Table 7.

## Catch Rates

## Individual Fishers

We compared the total and lingcod CPUEs among the four primary fishers and found no significant differences in catch rates (Table 1), indicating that the individual catch rates are comparable. Therefore, further analyses were done using the cumulative catch rates rather than individual fisher CPUEs.

## Light vs. Heavier Leaders

The change in leader strength may have affected catch rates. To verify this, we compared catch rates on light ( 7 kg ) and heavy ( 11 kg ) leader using a Wilcoxon signed rank test (Table 2). Catch rates for lingcod and copper rockfish were not affected by leader strength; however, quillback (and therefore total fish catch rates) was significantly different. Both quillback rockfish CPUE and total fish CPUEs were greater using the light ( 7 kg ) leader (Table 2). The mean quillback CPUE was approximately 2.5 times higher using the light ( 7 kg ) leader than the heavy $(11 \mathrm{~kg}$ ) leader.

We also recorded the number of breakages of each type of leader in SA 15 and 16. The
 test with the Yates correction for continuity showed that the light leader broke significantly more often than the heavy leader ( $\chi^{2}{ }_{0.05,1}=4.8, \mathrm{p}=0.03$ ). However, neither leader broke very often.

## Catch Rate by Depth and Area

We compared lingcod catch rates between depth strata with all statistical areas pooled and found that significantly higher lingcod catch rates occurred in the shallow depth stratum (Table 3). When each statistical area was considered separately, only area 14 showed significantly higher catches in the shallow strata (Table 3). Due to the significant
differences in catch rates between depth strata, we looked for differences in lingcod catch rates among statistical areas within each depth stratum. Lingcod catch rates were significantly higher in both depth strata in SA 13,15 and 16 than SA 14 and than the shallow stratum of SA 17 (the deep stratum was not sampled in SA 17) (Table 3).

Copper rockfish catch rates were also higher in the shallow stratum than in the deep with all statistical areas pooled, and in SA 14,15 and 16 when each statistical area was considered separately (Table 3). In addition, catch rates in SA 13 also tended to be higher in the shallow stratum, although this difference was not statistically significant (Table 3). There were no significant differences among statistical areas when catch rates were compared within each depth stratum.

Quillback catch rates showed the opposite trend, with significantly higher catches in the deep stratum with all statistical areas pooled, and in SA 13 when each statistical area was considered separately (Table 3). When statistical areas were compared within each depth stratum, there was no significant difference in catch rates in the shallow stratum; however, greater catch rates of quillback rockfish were observed in SA 13, 14 and 16 than in SA 15 in the deep stratum (Table 3).

## Annual Catch Rate Comparisons

Lingcod, copper rockfish and quillback rockfish catch rates were compared among sampling year by depth stratum in SA 13, 15 and 16 (Tables 4 and 5, Figures 3-11). Lingcod catch rates improved significantly in both depth strata in SA 13 and 15 (Table 4). In SA 13, 2004 lingcod catch rates are significantly greater than 1987 and 1988, but are not different from 1986. There were no pair-wise differences in the deep stratum (Figure 3). Lingcod catch rates in SA 152004 exceeded rates from 1985 in both depth strata (Figure 3). Lingcod catch rates did not change among years in SA 16 in either depth stratum (Figure 4).

The only significant difference in copper rockfish catch rates among years occurred in the shallow depth stratum in SA 13 (Table 5). Catch rates were significantly lower in 2004 and 1987 than in 1986 or 1988 (Figure 5). Copper rockfish catches were uniformly low in the deep depth strata of SA 15 and 16 in all years (Figure 6 and 7).

Quillback rockfish catch rates differed among years in the shallow stratum in 13 and 16 (Table 5). In the shallow stratum of SA 13, three significantly different groups exist: 1986, 1987-1988, and 2004, with CPUE decreasing over time. Although not significant, a trend for lower catch rates in 2004 also exists in the deep stratum (Figure 8). Quillback catch rates in the shallow stratum of SA 16 were significantly lower in 2004 than 1986 and 1985 (Figure 10). 2004 catch rates in the deep stratum of SA 16 and both strata of SA 15 also tended to be lower in 2004 than in previous years, but the differences were not significant (Figure 9 and 10).

Difference in quillback rockfish CPUE between the light ( 7 kg ) leader (used in previous surveys) and the heavy leader ( 11 kg ) (used in this survey) makes annual comparisons difficult. However, in 2004, light leader were fished at all sites by one fisher in SA 15
and 16. Comparison of quillback CPUE using the 2004 light ( 7 kg ) leader data in SA 15 and 16 to previous survey CPUEs indicated that the only significant decrease in CPUE over time occurred in the shallow depth strata in SA 16. These results were consistent with the results obtained using the heavy ( 11 kg ) leader catch rates (Table 5). In addition the frequency of sets when no quillback were caught using the 7 kg ahd 11 kg leader was very similar or the same. In both SA 15 and 16, the proportion of zeros in the deep strata was the same for each leader type ( $67 \%$ in SA 15 and $55 \%$ in SA 16): In the shallow strata, slightly fewer sets had null catches of quillbacks using the light ( 7 kg ) leader ( $67 \%$ vs. $78 \%$ in SA 15 and $73 \%$ vs. $82 \%$ in SA 16 ).

## Biological Data

The mean length of male and female lingcod was 49.9 cm and 58.3 cm , respectively (Table 6, Figures 12 and 13). Female lingcod were significantly longer than males (Table 6). Significantly longer male and female lingcod were caught in the deep depth stratum than in the shallow stratum (Table 6). Longer male lingcod were caught in the shallow stratum of SA 16 and 13 than in SA 15. No other statistical differences in lingcod length among statistical areas exist (Figures 14 and 15).

Small sample sizes in some years precluded comparisons between depth strata across years. Both male and female lingcod sampled in the hook and line surveys have shown significant increases in size over time within the statistical areas sampled (Figure 16). Both male and female lingcod in SA 13 showed a significant increase in size over 1986 and 1988, and male lingcod size in 2004 increased over 1987 (Table 7). Only one female lingcod was captured in 1987; therefore, 1987 was excluded from the length analysis. Male lingcod caught in 2004 in SA 15 were significantly longer than those in 1986; however, there was no difference in female length (Table 7). Male and female lingcod caught in Area 16 in 2004 were greater in length than lingcod caught in 1986, but equal to 1985 (Table 7). Overall, there is a trend for increased size of both male and female lingcod (Figure 16).

Only $19 \%$ of the male lingcod were immature (Table 8). The majority of the male lingcod were either maturing ( $34 \%$ ) or mature, but at the spent or resting stage ( $46 \%$ ). Approximately $22 \%$ of the females were immature. As with the males, the majority of female lingcod were mature ( $49 \%$ ), at the spent or resting stage (Table 8).

## Diet Analysis

A total of 337 stomachs were examined (Table 9). Of these, 213 (63\%) were empty and 6 contained unidentified remains. The contents of the remaining 118 stomachs were identified to a general category (i.e. fish remains) or to species (Table 10). Most stomachs contained only one type of prey item (the "primary" prey), with only 13 stomachs containing "secondary" or "tertiary" prey items.

The most commonly consumed prey for lingcod captured in this study was fish, with $75 \%$ of the stomach examined containing unidentified fish, and a further $13 \%$ containing identifiable fish species (Table 10). The most common identified fish were Pacific herring ( $6 \%$ ) and rockfish ( $3 \%$ ). Shrimp and octopus were the most common identified invertebrates, at $12 \%$ and $10 \%$ of stomach contents respectively.

## DISCUSSION

Based on the assumption that catch rates measured as catch per unit of effort (CPUE) can be used as a relative index of abundance of lingcod, then lingcod abundance has increased over time in Statistical Areas 13 and 15 but not in SA 16. In SA 13, 2004 lingcod catch rates were greater than 1987 and 1988 catch rates but were not different from 1986 catch rates. Note that a dramatic drop in lingcod catch rates occurred in the shallow depth stratum in 1987 and the deep stratum in 1988 in SA 13 (see Figure 3). The size of male and female lingcod in SA 13, 15 and 16 has also generally increased in 2004.

We used a heavier fishing leader to address concerns that large lingcod could not be landed on the light ( 7 kg ) fishing leader used in previous surveys. Although the light leader did break more frequently than the heavy leader, the overall incidence of line breakage was relatively low and is therefore probably not a concern. Our gear calibration revealed that leader test did not affect catch rates for lingcod. Copper rockfish catch rates were also not affected by leader strength. However, quillback rockfish catch rates were significantly lower using the stronger leader. In this report, we had CPUE estimates available from light leader data to compare to previous surveys. Given there was very little improvement on line breakage and no change in CPUE for lingcod using the heavy leader, future surveys should use the light leaders for easier annual comparisons.

Different depth strata were sampled in 2004 than in previous surveys ( $0-25$ and 26-50 m in 2004 compared to $5-40 \mathrm{~m}, 41-70 \mathrm{~m}$, and $71-100 \mathrm{~m}$ in previous years). Depth strata were consistent with the 2003 survey of the Southern Strait of Georgia (Haggarty and King 2004) and the 1993 survey of SA 18 and 19 (Yamanaka and Murrie 1995). We reclassified the data from the 1980s using the modal depth (the depth at which most of the fishing occurred). This does, however, introduce bias into the study, since the range fished on some sets exceeds the range of the depth stratum into which they were reclassified. We found significant effects of depth on catch rates for many species including lingcod, copper rockfish and quillback rockfish. Therefore, depth strata with narrower ranges such as those used in this survey should be used to reduce one source of variability in catch rates and to strengthen temporal and spatial comparisons.

## ACKNOWLEDGEMENTS

Thanks to K. Mathias, V. Hodes and P. Winchell for their hard work in the field and to C. Fort for the use of the Lifetimer. Thank you to M. Surry for help with the preparation of this report. Thank you to J. Lochead for reviewing this work.

*2004 QCPUE using light (7 kg) leader.

Table 6. Length of male and female lingcod, captured June 14-July 9, 2004, by depth stratum and Statistical Area. Significant differences are shown in bold print. Female lingcod were longer than male lingcod and longer lingcod of both sexes were found in deeper water. The only significant difference in lingcod length among statistical areas was in the shallow depth stratum of SA 13 where male lingcod were longer than those in SA 15 and 16.

Figure 1. Locations of sites in Statistical Areas 13 and 15 of the Strait of Georgia sampled June 14-July 9, 2004. Previously sampled locations in are denoted by the $1 \times 1 \mathrm{~km}$ jig blocks.

Figure 2. Locations of sites in Statistical Areas 14, 16 and 17 of the Strait of Georgia sampled June 14-July 9,2004 . Previously sampled locations are denoted by the $1 \times 1 \mathrm{~km}$ jig blocks. No sites in SA 14 were previously sampled.

Figure 3. Boxplot representing lingcod CPUE (fish/hour) by depth stratum in Statistical Area 13, June 14July 9,2004 . A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep ( $26-50 \mathrm{~m}$ ). The median is indicated by the horizontal line in the box, while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers, while outliers are shown as * and ${ }^{\circ} .2004$ catch rates are significantly greater than 1987 and 1988 but equal to 1986 in the shallow stratum. No pair-wise difference exists in the deep stratum.

Figure 4. Boxplot representing lingcod CPUE (fish/hour) by depth stratum in Statistical Area 15, June 14July 9,2004 . A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep ( $26-50 \mathrm{~m}$ ). The median is indicated by the horizontal line in the box, while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers, while outliers are shown as * and ${ }^{\circ} .2004$ catch rates are significantly greater than 1985 rates in both depth strata.

Figure 5. Boxplot representing lingcod CPUE (fish/hour) by depth stratum in Statistical Area 16, June 14July 9, 2004. A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep ( $26-50 \mathrm{~m}$ ). The median is indicated by the horizontal line in the box, while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers, while outliers are shown as ${ }^{*}$ and ${ }^{\circ}$. No significant difference in catch rates exist.

Figure 6. Boxplot representing copper rockfish CPUE (fish/hour) by depth stratum in Statistical Area 13, June 14-July 9, 2004. A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep ( $26-50 \mathrm{~m}$ ). The median is indicated by the horizontal line in the box, while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers, while outliers are represented by * and ${ }^{\circ} .2004$ and 1987 catch rates in the shallow stratum are significantly lower than 1986 and 1988. No differences exist in the deep stratum.

Figure 7. Boxplot representing copper rockfish CPUE (fish/hour) by depth stratum in Statistical Area 15, June 14-July 9,2004 . A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep ( $26-50 \mathrm{~m}$ ). The median is indicated by the horizontal line in the box , while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers, while outliers are represented by ${ }^{*}$ and ${ }^{\circ}$. Catch rates are not significantly different.

Figure 8. Boxplot representing copper rockfish CPUE (fish/hour) by depth stratum in Statistical Area 16, June 14-July 9,2004 . A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep ( $26-50 \mathrm{~m}$ ). The median is indicated by the horizontal line in the box, while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers, while outliers are represented by ${ }^{*}$ and ${ }^{\circ}$. Catch rates are not significantly different.

Figure 9. Boxplot representing the quillback rockfish catch per unit of effort (fish per hour) by depth stratum in Statistical Area 13, June 14-July 9, 2004. A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep ( $26-50 \mathrm{~m}$ ). The median is indicated by the horizontal line in the box, while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers, while outliers are represented by * and ${ }^{\circ}$. Quillback catch rates in the shallow stratum decreased over time with three significantly different groups: 1986, 1987-1988, and 2004. The decreasing trend in the deep stratum is not significant.

Figure 10. Boxplot representing the quillback rockfish catch per unit of effort (fish per hour) by depth stratum in Statistical Area 15, June 14-July 9, 2004. A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep ( $26-50 \mathrm{~m}$ ). The median is indicated by the horizontal line in the box, while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers, while outliers are represented by * and ${ }^{\circ}$. Quillback catch rates are not significantly different although 2004 deep catch rates tend to be lower.

Figure 11. Boxplot representing the quillback rockfish catch per unit of effort (fish per hour) by depth stratum in Statistical Area 16, June 14-July 9, 2004. A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep ( $26-50 \mathrm{~m}$ ). The median is indicated by the horizontal line in the box, while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers, while outliers are represented by * and ${ }^{\circ}$. Quillback catch rates were significantly lower in 2004 in the shallow stratum and tended to be lower, but were not significant in the deep stratum.

Figure 12. Length frequency histogram for female lingcod caught in the Hook and Line Survey in Statistical Areas 13-17, June 14-July 9, 2004. A=Shallow (0-25m), B=Deep (26-50 m).

Figure 13. Length frequency histogram for male lingcod caught in the Hook and Line Survey in Statistical Areas 13-17, June 14-July 9, 2004. A=Shallow (0-25m), B=Deep (26-50 m).

A

B

Figure 14. Boxplot representing the female lingcod length by statistical area, June 14-July 9, 2004. A=Shallow ( $0-25 \mathrm{~m}$ ), B=Deep $(26-50 \mathrm{~m})$. The median length is indicated by the horizontal line in the box while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers while outliers are represented by * and ${ }^{\circ}$. No significant differences exist.

Figure 15. Boxplot representing the male lingcod length by statistical area, June 14-July 9, 2004. $\mathrm{A}=$ Shallow $(0-25 \mathrm{~m}), \mathrm{B}=$ Deep $(26-50 \mathrm{~m})$. The median length is indicated by the horizontal line in the box while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers while outliers are represented by * and ${ }^{\circ}$. Male lingcod caught in the shallow stratum in area 15 were smaller than the other two areas. No significant differences exists in the deep stratum.

## A

B

Figure 16. Boxplot representing $A$ ) male and $B$ ) female lingcod length by year. The median length is indicated by the horizontal line in the box while box edges depict the $1^{\text {st }}$ and $3^{\text {rd }}$ quartiles. The typical range of the data are represented by the whiskers while outliers are represented by ${ }^{*}$ and ${ }^{\circ}$. The length of both male and female lingcod caught in hook and line surveys tends to be increasing. Only one female lingcod was captured in 1987.
Appendix Table 1. Location, depth, time, and environmental characteristics for each fishing set for the 2004 hook and line survey of lingcod and
rockfish in the Strait of Georgia, June $14-$ July 8, 2004. SA = Statistical Area. Depth stratum $\mathbf{1 = 0 - 2 5} \mathbf{m}$ (shallow); depth stratum $2=\mathbf{2 6 - 5 0} \mathrm{m}$ (deep).
Bottom depth is the modal bottom depth over the duration of the set. See Appendix Table 8 for sea state, tide, current, and weather codes.

Appendix Table 2. Effort data by set and depth stratum for each fisher, and number of fish caught by species for the 2004 hook and line survey of lingcod and rockfish (RF) in the Strait of Georgia, June 14 - August 3, 2004. Numbers in brackets indicate fishing effort or number of fish caught while using the 7 ( 7 kg ) leader. Depth stratum (DS) $1=0-25 \mathrm{~m}$ (shallow); $2=26-50 \mathrm{~m}$ (deep). Note: In addition to the species indicated, one Chinook salmon smolt was also captured at the surface on a bare hook in set 13 on June 17.

Appendix Table 3. Capture depth (m), biological data, fisher ID, and leader weight for lingcod (Ophiodon elongatus) captured during the 2004 hook and line survey of lingcod and rockfish in the Strait of Georgia, June 14 - July 8, 2004. For sex and maturity codes, see Appendix Tables 9 and 10. SA = Statistical Area. Depth stratum (DS) $\mathbf{1}=\mathbf{0 - 2 5} \mathrm{m}$ (shallow); $2=\mathbf{2 6 - 5 0} \mathrm{m}$ (deep).

Appendix Table 6. Capture depth (m), biological data, fisher ID, and leader weight for dogfish (Squalus acanthias) captured during the 2004 hook and line survey of lingcod and rockfish in the Strait of Georgia, June 14 - July 8, 2004. For sex codes, see Appendix Table 9. SA = Statistical Area. Depth stratum (DS) $1=$ $0-25 \mathrm{~m}$ (shallow); $2=\mathbf{2 6 - 5 0} \mathrm{m}$ (deep).

${ }^{1}$ Fish observed but not landed

Appendix Table 7. Capture depth (m), biological data, and fisher ID for Chinook salmon (Oncorhynchus tshawytscha) ${ }^{1}$, Greenstripe rockfish (Sebastes elongatus), Yelloweye rockfish (S. ruberrimus), Kelp greenling (Hexagrammos decagrammus), Cabezon (Scorpaenichthys marmoratus), and Rock sole (Lepidopsetta bilineata) captured during the 2004 hook and line survey of lingcod and rockfish in the Strait of Georgia, June 14 - July 8, 2004. For sex and maturity codes, see Appendix Tables 9 and 10. SA = Statistical Area. Depth stratum (DS) $\mathbf{1}=\mathbf{0 - 2 5} \mathrm{m}$ (shallow); $2=\mathbf{2 6 - 5 0} \mathrm{m}$ (deep).

${ }^{\text {T }}$ Single Chinook salmon smolt was caught on a bare hook at the surface.
${ }^{2}$ Fish frozen at the end of the field day and sampled in the lab at a later date.
${ }^{3}$ Released.

Appendix Table 8. Codes used to describe sea state, tide, current, and weather.

| Code | Description |
| :--- | :--- |
| Sea State |  |
| 1 | calm |
| 2 | ripple |
| 3 | chop |
| 4 | swell |
| Tide |  |
| 1 | ebb |
| 2 | flood |
| 3 | high |
| 4 | low |
| Current |  |
| 0 | none |
| 1 | weak (minimal) |
| 2 | moderate-weak |
| 3 | moderate |
| 4 | moderate-strong |
| 5 | strong |
| Weather |  |
| 1 | sun |
| 2 | rain |
| 3 | partly cloudy |
| 4 | overcast |
| 5 | high cloud |
| 6 | fog/overcast |

Appendix Table 9. Codes used to indicate sex.

| Code | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | Blank (--) |
| ---: | :---: | :---: | :---: | :---: |
| Description | Male | Female | Unknown | Not examined |

Appendix Table 10. Reproductive maturity codes.

| Maturity Stage | Male | Female |
| :---: | :---: | :---: |
| Lingcod or Greenling (Hexagrammidae) |  |  |
| STAGE 1: <br> Immature | - Testes threadlike to ribbonlike <br> - Colour transparent-white to white | - Ovaries small and translucent <br> - Colour pink or white-pink <br> - Eggs not visible |
| STAGE 2: <br> Maturing - small | - Testes larger, ribbonlike <br> - Colour white to very 7 brown | - Ovaries fill about $1 / 4$ to $1 / 3$ of body cavity <br> - Colour orange and opaque or semi-translucent <br> - Blood vessels pronounced on the ovary |
| STAGE 3: <br> Maturing - large | - Testes fill $1 / 3$ of body cavity <br> - Colour whiter than in Stage 2 | - Ovaries fill about $1 / 3$ to $2 / 3$ of body cavity <br> - Colour orange. <br> - Blood vessels pronounced on the ovary <br> - Eggs opaque |
| STAGE 4: Mature | - Testes fill $1 / 3$ to $2 / 3$ of body cavity <br> - Colour white <br> - Cross sectioning of testis produces sperm at centre of tissue | - Ovaries fill $2 / 3$ to $4 / 5$ of the body cavity <br> - Eggs opaque <br> - Colour orange to white |
| STAGE 5: Ripe | - Testes fill $2 / 3$ or more of the body cavity <br> - Colour white <br> - Testis lobes fully developed <br> - Sperm released from vent with s7 pressure on body exterior | - Ovaries fill near all of the body cavity <br> - Colour opaque orange to white <br> - Eggs may be loose inside the ovary |
| STAGE 6: Spent | - Testes moderate in size <br> - Colour tan-brown with some white still evident <br> - Cross sectioning of testis reveals some remaining sperm in centre of gonad | - Ovaries fill $1 / 3$ to $2 / 3$ of the body cavity. <br> - Colour purple and may be bloodshot. <br> - Ovaries flaccid; some eggs may remain <br> - Reabsorbing <br> - Recovering |
| STAGE 7: Resting | - Testes relatively smaller and firm <br> - Colour tan-brown | - Ovaries fill less than $1 / 3$ of the body cavity <br> - Colour often pink <br> - Ovaries firm |
| Rockfish (Sebastes spp.) |  |  |
| STAGE 1: Immature | - Testes are translucent and string-like. <br> - Located in the back of the body cavity | - Ovaries are translucent and very small <br> - Colouring can be clear, amber, or yellow |
| STAGE 2: <br> Maturing - small | - Testes are ribbon-like and swelling in size <br> - Colour is translucent-white or brown-white | - Ovaries developing for this year's cycle but still relatively small <br> - Ovaries semi-translucent or opaque <br> - Colouring usually yellow, but can be 7 pink |
| STAGE 3: <br> Maturing - large | - Testes are large <br> - Colour is translucent-white | - Ovaries large and contain eggs that can be distinguished by direct observation <br> - Eggs opaque and orange-yellow or cream |
| STAGE 4: Mature | - Testes are very large and easily broken <br> - Colour is white | - Ovaries are large <br> - Eggs are translucent and orange-yellow or cream |
| STAGE 5: Ripe | - Testes are very large with free flowing sperm <br> - Colour is white <br> - Sperm is running when gonad is cut or fish's body cavity is pressed | - Ovaries large and full of eyed eggs or larvae <br> - Eyed eggs translucent yellow with visible black dots <br> - Larvae grey to grey-green with black dots <br> - Eyed eggs and larvae flow freely from vent when pressure applied to body cavity |
| STAGE 6: Spent | - Testes are smaller. <br> - Colour is creamy-brown. <br> - When testes are broken, some remaining sperm is evident but is of a thicker consistency, not flowing | - Ovaries large and flaccid <br> - Colour red to red-purple <br> - A few larvae may be present |
| STAGE 7: <br> Resting | - Testes are smaller and ribbon-like <br> - Colour is brown | - Ovaries firm and moderate in size <br> - Colour red-grey; some with black blotches |
