## Canadian Technical Report of Fisheries and Aquatic Sciences

Technical reports contain scientific and technical information that contributes to existing knowledge but which is not normally appropriate for primary literature. Technical reports are directed primarily toward a worldwide audience and have an international distribution. No restriction is placed on subject matter and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Technical reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers $1-456$ in this series were issued as Technical Reports of the Fisheries Research Board of Canada. Numbers 457-714 were issued as Department of the Environment, Fisheries and Marine Service, Research and Development Directorate Technical Reports. Numbers 715-924 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Technical Reports. The current series name was changed with report number 925.

Technical reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport technique canadien des sciences halieutiques et aquatiques

Les rapports techniques contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui ne sont pas normalement appropriés pour la publication dans un journal scientifique. Les rapports techniques sont destinés essentiellement à un public international et ils sont distribués à cet échelon. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports techniques peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports techniques sont résumés dans la revue Résumés des sceiences aquatiques et halieutiques, et ils sont classés dans l'index annual des publication scientifiques et techniques du Ministère.

Les numéros là 456 de cette série ont été publiés à titre de rapports techniques de l'Office des recherches sur les pêcheries du Canada. Les numéros 457 à 714 sont parus à titre de rapports techniques de la Direction générale de la recherche et du développement, Service des pêches et de la mer, ministère de l'Environnement. Les numéros 715 à 924 ont été publiés à titre de rapports techniques du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 925.

Les rapports techniques sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

#### Abstract

Stanley, R.D, Olsen, N., Workman, G., Cleary, J., and de la Mare, W. 2007. A review of the groundfish Queen Charlotte Sound bottom trawl survey (2003-2005). Can. Tech. Rep. Fish. Aquat. Sci. 2709: viii +59 p.

The Queen Charlotte Sound groundfish bottom trawl survey was conducted jointly by the Canadian Groundfish Research and Conservation Society, and Fisheries and Oceans Canada in 2003, 2004 and 2005. The survey covers Queen Charlotte Sound and the southern portion of Hecate Strait. The purpose of the survey is to provide relative abundance indices for as many benthic and near benthic fish species as is reasonable while obtaining the supporting biological samples of size and age composition. It covers the populations on the continental shelf region of the central coast and complements the three other outer coast trawl surveys, as well as numerous other surveys which provide groundfish indexing. The purpose of this document is to review the results and costs of this survey after the first three years. The document specifically addresses the following elements: 1) the precision/accuracy of the survey; 2) the costs of the survey; 3) the expectations of the survey; 4) whether the survey should be continued, and 5) how, or if, the survey should be modified. The analysis makes use of a survey simulator to characterize the effectiveness of the survey, as well as explore potentially more costeffective designs. The document recommends that the survey should be continued in its current configuration with relatively minor operational changes.

## RÉSUMÉ

Stanley, R.D, Olsen, N., Workman, G., Cleary, J., and de la Mare, W. 2007. A review of the groundfish Queen Charlotte Sound bottom trawl survey (2003-2005). Can. Tech. Rep. Fish. Aquat. Sci. 2709: viii +59 p.

L'enquête saine de chalut du fond de poisson de fond de la Reine Charlotte a été conduite conjointement par la société canadienne de recherches et de conservation de poisson de fond et la pêche et les océans Canada en 2003, 2004 et 2005. L'aperçu couvre le bruit de la Reine Charlotte et la partie méridionale du détroit de Hecate. Le but de l'aperçu est de fournir à index relatifs proportionnés d'abondance pour autant d'espèces benthiques de poissons de même que raisonnable tout en obtenant les échantillons biologiques le support de structure d'âge de taille et. Il couvre les populations sur la région de plateau continental de la côte centrale tandis que compléter les trois autres enquêtes externes de chalut de côte, comme encore 14 examine qui fournissent l'indexation de poisson de fond. Le but de ce document est de passer en revue les résultats et les coûts de cet aperçu après les trois premières années. Le document adresse spécifiquement les éléments suivants : la 1) précision/exactitude de l'aperçu ; 2) les coûts de l'aperçu ; 3) les espérances de l'aperçu ; 4) si l'aperçu devrait être continué, et 5) comment, ou si, l'aperçu est modifié. L'analyse se sert d'un simulateur d'aperçu pour caractériser l'efficacité de l'aperçu, aussi bien qu'explorent des conceptions potentiellement plus rentables. Le document recommande que l'aperçu devrait être continué dans sa configuration courante avec les changements opérationnels relativement mineurs.

## INTRODUCTION

The intent of the Groundfish Queen Charlotte Sound survey (GF-QCSd) is to provide accurate relative abundance indices for as many benthic and near benthic fish species as is reasonable while obtaining the supporting biological samples of size and age composition (Sinclair et al. 2003, Stanley et al. 2004). The survey indexes populations in Queen Charlotte Sound (QCSd) and the southern portion of Hecate Strait (Figure 1). It complements the three other outer coast trawl surveys, as well as numerous other surveys which provide groundfish indexing (Figure 2, Appendix 1).

This document addresses the results, costs and expectations of the survey, whether the survey should be continued, and if so, should we consider any major changes with respect to frequency, or number of tows. This document is not intended as a user's guide to the survey data, nor does it document the evolution of the survey methodology. In particular, we plan a second Operations Manual that will document how we conduct the survey. This will emphasize the steps taken to standardize the fishing and sampling procedures. A second document and/or a website will provide guidance on data analysis.

Figure 1. Coverage of GF-QCSd survey area, $50-500 \mathrm{~m}$, point-to-point coastline boundaries, and closed areas.

Figure 2. Location of GF-QCSd survey in relation to the other major groundfish bottom trawl surveys.

## METHODS

## SURVEY DESIGN

The survey follows a stratified random design. The survey area is divided into two area and four depth strata (Figure 3 and Table 1). We treat the total area as $6,9204-\mathrm{km}^{2}$ potentially trawlable blocks. For each survey, a set of blocks is drawn randomly from the overall population, subject to proportional allocation by stratum.

Figure 3. GF-QCSd survey region showing area strata boundary and depth strata. The arrow indicates a portion of the survey sampling frame to show the relative size of the $4-\mathrm{km}^{2}$ blocks.

Table 1. Number of blocks within each stratum.

| Area Stratum | Depth Stratum (m) | Number of Blocks |
| :--- | ---: | ---: |
| South | $50-125$ | 1,420 |
|  | $125-200$ | 1,460 |
|  | $200-330$ | 760 |
|  | $300-500$ | 141 |
| Sub-total |  | 3,781 |
| North | $50-125$ | 546 |
|  | $125-200$ | 1,172 |
|  | $200-330$ | 1,098 |
|  | $300-500$ | 323 |
| Sub-total |  | 3,139 |
| Total |  | $\mathbf{6 , 9 2 0}$ |

The survey was designed to be conducted by one charter vessel, commencing in early July and finishing in the second week of August. The timing was chosen to take advantage of good summer weather and a period when most species are not in transition from their late winter to late summer depths.

Previous work identified a target sampling density of 240 tows per survey (Sinclair et al. 2003, Stanley et al. 2004). The density was chosen based on the objective of achieving a relative error (estimated from observational error) for abundance indices of
less than 0.40 for many of the higher profile populations in the survey area. This was based on the assumption that the survey would be conducted at least every two years.

For this discussion paper, we have adopted the following syntax with respect to the discussion of survey variance:

1. We reserve Coefficient of Variance (CV) to note the relative variation in the parent population of observations of catch rate within a survey.
2. We reserve Relative Error ( $\boldsymbol{R E}$ ) to note the relative variance in the overall estimate of catch rate for one year of survey. This statistic reflects the variance of the index point caused by combined effects of Process, Observation and Measurement Error.
3. With respect to sources of error in a survey, we reserve:
a. Process Error (PE) to note the variance caused by changes in the fish abundance among years. Within PE we divide the source of the variance into two types:
i. Process Error (PE-A) owing to an actual change among years in abundance within the survey error (we assume a closed system);
ii. Process Error (PE-C) owing, for example, to a change among years in the catchability ${ }^{1}$ for that population.
b. Observation Error (OE) to note the sampling variance caused by the variation among catch rates within the set of observations from one survey year;
c. Measurement Error (ME) to note the added variance caused by imprecision in estimating the catch by species in each tow. We treat this component as negligible in comparison with the others.

Because of the difficulty in separating the confounding influence of $P E-A$ and $P E-$ $C$, this additional source of error is usually ignored in presenting the imprecision of a survey (or for that matter CPUE analysis). The $O E$ alone is used as a surrogate for the overall $R E$ of the survey, although only one contributing component of the variance.

Stanley et al. (2004) proposed a set of crude $R E_{O E}$ standards (based only on $O E$ ) for characterizing the capability of a survey to track a population as:

- excellent $=<0.20$
- good $=0.20-0.30$
- adequate $=0.30-0.40$
- poor $=0.40-0.60$
- very poor $=>0.60$

Based on these standards, they reported that the GF-QCSd survey would yield at least adequate precision for 34 populations. These populations represented $80 \%$ of the commercial landings or the survey catches. The total effort of 240 tows was then allocated to the eight strata for the 2003 survey to minimize the sum of the $R E_{O E, s}$ 's across the most abundant 50 populations (s), equating to equal weighting among populations.

[^0]Each survey starts with a set of proposed blocks but since many of these blocks turn out to be un-trawlable, the execution requires a method for achieving 240 successful tows. After trying different approaches in 2003 and 2004, we settled in 2005 on a method wherein the survey commences with a primary set much greater than the target 240 (308 in 2005) under the condition that we accept the end result whether or not it is over or under the target of 240 . We calculated the necessary overage by examining the failure rate by stratum in the first two years. The projected sample set was then fine-tuned after review by the charter skipper by removing or adding randomly chosen blocks.

A successful tow was defined as having been towed for at least 15 minutes, with a target tow time of 19 minutes. Originally a towing time of 20 minutes was the target, but the mensuration data indicated that the net continued to fish an extra 1-2 minutes after engaging the winches.

A block was either successfully fished or rejected. Sometimes it was rejected without inspection because the charter captain, based on prior knowledge of the area, said it would be a waste of time to travel to the block. This was a rare occurrence. The second means for rejecting a block was after inspection on the grounds revealed the block to be unsuitable for trawling. There were no formal rules about how much time should be spent examining the block prior to rejection. Finally, the block could be rejected after trying and failing to complete a successful tow.

## GEAR AND ENVIRONMENTAL MONITORING

We monitored and captured SCANMAR sensor output for doorspread, headrope height, water temperature, and current velocity and attached a bottom contact sensor to the footrope to monitor whether the groundrope was in contact with the bottom. A Seabird SBE39 temperature/depth probe was used in all tows for 2003-2005. These probes were mounted on the headrope and downloaded along with the bottom contact sensor, twice daily. We will begin using an oxygen probe starting in 2007.

## CATCH SORTING AND BIOLOGICAL SAMPLING

We sorted the entire catch unless it was estimated to be greater than $3,000 \mathrm{~kg}$. In these cases, we obtained the captain's estimate of the gross weight, then sorted and weighed all but the dominant species, which was then estimated by subtraction.

The priority during field operations was to conduct as many tows as possible, so the overall amount of biological sampling was constrained by the time remaining to staff after sorting and weighing the catches (see Appendix 2 for the sampling protocol). The first sampling priority was to obtain length/sex (L/S) information on all fish species in the catch. The second priority was to obtain at least two length/sex/weight (L/S/W) samples per stratum for the most common species. The collection of ageing structures and macroscopic maturity classification was third in priority.

The intent of the ageing samples was to collect at least 10 samples of $>30$ fish for principal commercial populations. A secondary ageing target was to obtain at least one "starter" sample for lower profile species.

## ESTIMATION OF THE RELATIVE CATCH RATE INDEX

Catches were converted to an area-swept biomass index as described in Appendix 3 (Stanley et al. 2004).

## THE SIMULATOR

The effectiveness of the survey was examined through use of a survey simulator (Schnute and Haigh 2003, Stanley et al. 2004) to examine how closely we can expect a survey to track a given change in abundance over a specified time period. This simulator receives as input:

- a hypothetical scenario of population change;
- a configuration of the GF-QCSd survey;
- actual survey data for incorporating the variance.

A scenario is defined first by considering a hypothetical change in the population, for example a decline of $70 \%$ in arrowtooth flounder abundance over 10 years. A single run of the simulation generates one potential time-series of five additional biennial survey points over the specified period of 10 years, given the variance expected in the survey. The observed trend of five points is fit to a monotonic trend and the observed slope is compared with the modeled change. The simulator models a specified configuration of the survey with respect to the number of tows, allocation and frequency (annual, biennial, triennial). For this review, we only modeled the case where population change is manifest by a change in the catch rate of non-zero tows. The proportion of zero tows stays constant.

The single run is considered to have tracked the population accurately if the time series of simulated survey points indicates a change close to the modeled change. "Close" is defined as falling between arbitrarily chosen upper and lower tolerance limits, or design points. For example, if the true change were a decline of $70 \%$, a run is considered to have provided a close result if it indicates a decline between 50 and $80 \%$. Finally, the simulation is repeated 5,000 times. The survey is considered accurate for that scenario if a sufficient proportion of the runs, for example $80 \%$, indicate a change within the design points.

Observational error is derived from the actual survey results. The user has three options for incorporating the error (see Appendix 4):

- Option 1: $R E_{\mathrm{OE}, \mathrm{s}, \mathrm{y}}$ is calculated as the $O E$ from one population $s$ and one specific survey year $y$;
- Option 2: $R E_{O E, s, \text { pooled }}$ is calculated as the $O E$ after pooling 2003-2005 data, without scaling among years,
- Option 3: $R E_{O E, s, y}+P E$ is calculated as the OE from any one year plus process error input as a fixed amount.

Option 1 underestimates the variance (imprecision) of the survey by ignoring the $P E-C$. It therefore represents an overly optimistic view of the survey precision. Option 2 , on the other hand, may overestimate the variance. While correctly incorporating PE-C (over the three years), it also, and incorrectly, adds the variance owing to a real change in abundance over the three years ( $P E-A$ ). Option 3 is not necessarily pessimistic or optimistic but assumes there is information available on the $P E-C$, such as using the generalized estimate of $R E$ of 0.2 from Francis et al. (2003) or 0.29 for haddock from Pennington (1985).

It should be noted that this modelling of the GF-QCSd survey tends to underestimate the precision of this survey by treating the start point of the simulation as being based on only one survey. The additional intervening survey point provided by the 2004 survey will help to anchor the start of each time series in the special case of the GFQCSd survey.

We demonstrate the use of the simulator with a hypothetical case involving arrowtooth flounder. The recent decision by the Department to increase harvests of arrowtooth flounder was supported, in part, by the expectation that GF-QCSd and other surveys would provide accurate indexing of the populations. While reasonable, this statement begs an answer to the question of how well these surveys will index the population. We can directly pose the question to the simulator of whether the survey would reliably detect a hypothetical change over time. For example, do we expect the GF-QCSd survey to accurately track a $70 \%$ decline over 10 years? Would it consistently indicate a decline, and how often would it accurately indicate the size of the decline? Prior to supporting higher harvest, managers might request assurance that should the population decline by $70 \%$ over the next 10 years, the survey would not only show some level of decrease at least $99 \%$ of the time, but should accurately indicate a decrease of between $50 \%$ and $80 \%$ at least $80 \%$ of the time. Raising the quota would be conditional on knowing that the survey meets this or a similar performance criterion.

The simulator produces 5,000 possible survey outcomes for each survey year by generating 240 tow results (with stratification) from the parent population observed in the survey. For each year, a biomass index is calculated from the tow results and scaled by a constant representing the true population decrease (Figure 4). A single time series of the survey consists of any set of yearly indices over the 10 years of the simulation (Figure 5).

Figure 4. Boxplots of 5,000 simulated survey trajectories. Each boxplot indicates the distribution of survey estimates within each survey year; with the underlying population declining by $70 \%$ over 10 years (see Appendix 4: Figure 2 for explanation of boxplot graph)

Figure 5. Example of a single simulated trajectory from the data presented in Figure 4. The red line indicates the best-fit slope of the trajectory and the green line indicates the actual simulated trend.

Figure 6. Number of runs out of 5000 grouped by the estimate of the proportional decrease of $70 \%$ (indicated by the blue line) over 10 years for arrowtooth flounder. "In bounds" indicates the proportion of the simulation runs which indicated a decrease of between 20 and $50 \%$ of the original biomass (within the red vertical lines). "Positive" indicates the proportion of runs which indicated a positive change in biomass (to the right of the vertical green line).

The simulation suggests that the GF-QCSd survey will correctly indicate that the population has decreased $100 \%$ of the time, and estimated the "correct" amount of the decrease $96 \%$ of the time. Using this scenario as a test, it is reasonable to advise managers that this survey will provide adequate indexing to support a "test" of arrowtooth flounder productivity.

## RESULTS

## OPERATIONAL RESULTS

Each year the survey began in the first week of July and lasted about five weeks (Table 2). We were fortunate with the weather in losing only four days over the three years. We will probably continue to forecast three or four lost days per survey (weather and breakdown) in the specifications of the Request for Proposal (RFP).

Table 2. Summary of GF-QCSd survey operational days (2003-2005).

|  | $\mathbf{2 0 0 3}$ | $\mathbf{2 0 0 4}$ | $\mathbf{2 0 0 5}$ |
| :--- | ---: | ---: | ---: |

| End day: Offload Nanaimo | August 10 | August 9 | August 7 |
| Fishing days | 28 | 26 | 24 |
| Travel (begin and end) | 3 | 3.5 | 3 |
| Offload days | 4 | 4 | 4 |
| Weather days | 2 | 0 | 2 |
| Breakdown | 1 | 1.5 | 0 |
| Total Days | 38 | 35 | 33 |
| Keeper tows | 239 | 240 | 228 |
| Unusable tows | 21 | 37 | 32 |
| Inspected un-fished blocks | 16 | 53 | 49 |
| Tows/overall days | 6.3 | 6.9 | 6.9 |
| Usable tows/fishing day | 8.5 | 9.2 | 9.5 |

The workload on deck is at the upper limit for research surveys, mostly owing to the fact that we follow a sunrise to sunset workday, during the longest days of the year. In early July, the first tow comes out of the water at 0600 and last tow at about 2100, with data still to process. The survey averages over nine tows per full fishing day, and sometimes reaches 12 successful tows per day. As designed, only rarely did we have to pause in the fishing to clear up a backlog of sorting and sampling.

The net cost of the survey ranged from $\$ 380-420 \mathrm{~K}$, with the cost borne at a ratio of about 80:20 between the Canadian Groundfish and Research Society (CGRCS) and DFO (Table 3).

Table 3. Estimated costs (\$) of the GF-QCSd survey (2003-2005).

| Total Coast | 417,000 | 381,000 | 377,400 |  |

## Completed Tows by Stratum

After examining the 2003 results, we re-allocated a few tows to the shallow stratum in 2004 (Table 4). It appeared that a modest reallocation would greatly improve precision for the shallow species with negligible impact on the deeper species (Stanley et al. 2004). However, we found that we lost a significant amount of time searching for trawlable locations in the shallow stratum. Furthermore, these tows are consistently on
marginally towable bottom. Towing on rough bottom in shallow water ( 50 m ) adds significantly to the risk of losing or damaging the net and sensors, as well as representing an increased safety risk to the vessel and staff should the gear hang-up. We therefore moved to an allocation between the 2003 and 2004 versions for the 2005 survey (Table 4). We have not re-examined the allocation for this discussion and do not anticipate a reevaluation prior to the 2007 survey. In subsequent years, as the shallow stratum becomes fully mapped, we can re-allocate to the shallow since the costs and risks will diminish.

Table 4. Targeted and delivered allocation per stratum (2003-2005).

| Area | Depth Stratum |  | $\mathbf{2 0 0 3}$ |  | $\mathbf{2 0 0 4}$ |  | $\mathbf{2 0 0 5}$ |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| Survey Total |  | $\mathbf{2 4 0}$ | $\mathbf{2 3 9}$ | $\mathbf{2 4 0}$ | $\mathbf{2 4 0}$ | $\mathbf{2 4 0}$ | $\mathbf{2 2 8}$ |  |  |

We fell short of our target 240 tows in 2005 although we started with a set of 308 blocks. As the number of previously surveyed blocks increases, we will become more accurate in estimating the required overage.

## Completion of the Sampling Frame

We successfully fished $74 \%$ of all randomly chosen blocks over the three years (Figure 7, Table 5). Our success rate will increase and search time decrease as we slowly delete untrawlable blocks from the sampling frame. We have now visited 897 blocks or $13 \%$ of the 6,920 blocks in the sampling frame.

Table 5. Number of blocks allocated and successfully completed by stratum (2003-2005).

| Area Stratum | Depth Stratum |  | 2003 |  |  | 2004 |  |  | 2005 |  |  |

| Survey Total |  |  | 276 | 238 | 86.2 | 334 | 240 | 71.9 | 308 | 228 | 74.0 |

Figure 7. Composite of all three years with all successfully completed (green) or rejected (red) blocks.
It is obvious from Figure 8, which compares the set of tows for 2005 with the main areas of trawl fishing, that we can expect a significant contribution of observational error owing to the chance distribution of tows. The number of tows that fall within blocks that are associated with high commercial catch rate blocks will vary among years.

Figure 8. Comparison of the 2005 sampling frame with main areas of bottom trawl activity.

## Fate of Rejected Blocks

Discussions in 2003 recommended that if a block were rejected during a survey, the same block would be maintained in the sampling frame for future surveys until it was rejected two more times. The concern was that a charter captain might be too cautious and tend to permanently remove too many fishable blocks from the sampling frame. We were trying to obtain the most complete coverage possible and were concerned that a high rejection rate might result in less representative coverage.

However, after three years, it appears that, with the exception of the shallow strata, we are covering most of the survey area. Furthermore, as the set of successful blocks grows, it becomes increasingly difficult for a future skipper to be overly cautious. An increasing number of the blocks will have already been fished, or the new blocks will be surrounded by fishable blocks. We recommend changing the protocol to remove a block after one rejection. Searching for towable blocks is a major cost and having to return two more times to a previously rejected block seems pointless.

## Fishing within a Block

The fishing captain is requested to fish the block approximately through the centre and parallel to the depth contours. However, many of the bocks would be unfishable if this rule had to be strictly followed. Therefore, the captain is allowed to choose a different path if is necessary to complete the block (Figure 9). As the surveys are repeated, and we begin repeating blocks, we will request that the skipper attempt to
follow the previous track. This will reduce time spent searching for trawlable bottom, and minimize the footprint of the survey, such that not all the area within a block will be fished.

Figure 9. Selected tow tracks from the southeast coast of Moresby Island in 2004.

## FISHING MENSURATION/BRIDGE LOG DATA CAPTURE

We did not encounter any significant problems with the gear mensuration or capturing oceanographic data (Figure 10 to Figure 13). In addition to providing background data for tracking environmental change and supporting ecosystem research, we expect that analyses of these data will be useful for explaining some of the $P E-C$ in catch rates, leading to more precise indexing.

Figure 10. Gear mensuration overview. The top panel shows the location of the fished block and the trajectory of the tow track with start and end bottom contact times indicated by red Xs. The middle panel represents the doorspread and the bottom panel the net opening height and distance off bottom, over the duration of the tow. The light blue symbols on the bottom panel indicate catch sensor activity and probably represent fish entering the net. Note on the bottom panel the location where the trawl net jumps off the sea floor at approximately 54 minutes after the hour. The dashed and solid lines on the middle and bottom panels represent the gear deployment/retrieval times, and the begin/end bottom contact times, respectively.

Figure 11. Example bottom contact profile from the NMFS bottom contact sensor.

Figure 12. Example temperature and depth profiles from the Seabird 39 probe.

Figure 13. Interpolated bottom temperature from Seabird 39 temperature data in 2003 (a) and 2004 (b). Note the interpolation will be affected by location of the tows, which varies among years.

## TOTAL CATCH AND CATCH FREQUENCY

About 100 t of fish are captured during each survey, with $30-40 \%$ retained for sale (Table 6, Figure 14). We conducted a full sort of most tows. When we made a large tow of a retained species the weight was usually visually estimated but we were able to corroborate the values using the dockside monitoring program (DMP) estimates. Most of
the tows during each trip were completely weighed, thus the large tows would be the difference between the DMP estimate and the weighed tows.

Table 6. Total catch and number of species caught (2003-2005).

|  | $\mathbf{2 0 0 3}$ | $\mathbf{2 0 0 4}$ | $\mathbf{2 0 0 5}$ |
| :--- | ---: | ---: | ---: |
| Total Catch (kg) | 90,116 | 116,683 | $\mathbf{1 0 7 , 0 3 4}$ |
| Retained Catch (kg) | 37,476 | 47,291 | 39,591 |
| Retained Catch (\%) | 42 | 41 | 37 |
| Retained Catch Estimated Value (approx. \$) | 34,600 | 48,900 | 49,600 |
| Discarded Catch (kg) | 52,640 | 69,393 | 67,443 |
| Mean catch per tow (kg) | 377 | 486 | 469 |
| Total number of species | 172 | 244 | 254 |
| Total number of fish species | 105 | 125 | 124 |
| Total number of invertebrate species | 65 | 115 | 127 |
| Mean number of species per tow | 16 | 20 | 25 |
| Mean number of fish species per tow | 13 | 14 | 16 |
| Mean number of invertebrate species per tow | 3 | 6 | 8 |

Figure 14. Frequency plot of catch weight per tow for each year of the survey.
Frequency of occurrence was similar among years for most species. Exceptions included Pacific hake which increased in frequency over the three years (Table 7).

Table 7. Frequency of occurrence per year (2003-2005).

| Species | 2003 | 2004 | 2005 | Average |

## SURVEY PRECISION

The $R E_{O E, s, y}$ 's are similar among years, with a few exceptions such as Pacific hake, Pacific cod and rougheye rockfish (Table 8), Appendix 5). The relation between the average estimate of $R E_{O E, s, y}$ over the three years tends to equal the pooled estimate ( $R E_{\text {OE, }, \text {,Pooled }}$ ) for the lowest variance populations ( $\mathrm{RE}<0.20$ ). The discrepancy appears to accelerate with the $R E$. Averaged over the species shown in Table 9, the discrepancy equates to adding a $P E$ of about 0.13 , not unlike the value of 0.2 noted by Francis et al. (2003), especially if we were to include the additional species with a $R E$ greater than 0.60.

Table 8. Survey $R E_{O E, s, y}$ 's for each year and all three years combined (pooled) for species with a mean $R E_{O E, s, y}<0.4$.

| Species |  |  |  |  |  |

## SURVEY ACCURACY

We used the survey simulator to examine the accuracy of the survey for tracking populations in Queen Charlotte Sound. In the first set of scenarios, we examined the accuracy of the survey in tracking a doubling of a population over 10 years (Table 9, Figure 15 to Figure 20). All results used $R E_{O E, s, P o o l e d}$.

Table 9. Summary of results in testing how well the GF-QCSd survey can track a doubling of population over 10 years using $R E_{O E, S, P o o l e d}$.

| Species | $R E_{\text {OE,s,Pooled }}$ | $R E_{\text {OE,s,2005 }}$ | \% correct <br> within 1.5 and <br> 3.0 times | \% positive | Approx. tows <br> required to be <br> correct $80 \%$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Dover sole |  |  |  |  |  |

Figure 18. Simulation results for rougheye rockfish under the 2X increase scenario. "In bounds" indicates the proportion of the simulation runs which indicated an increase from 1.5 times and 3.0 times the original biomass (within the red vertical lines). "Positive" indicates the proportion of runs which indicated a positive change in biomass (to the right of the vertical green line).

Figure 19. Simulation results for canary rockfish under the 2 X increase scenario. "In bounds" indicates the proportion of the simulation runs which indicated an increase from 1.5 times and 3.0 times the original biomass (within the red vertical lines). "Positive" indicates the proportion of runs which indicated a positive change in biomass (to the right of the vertical green line).

Figure 20. Simulation results for bocaccio under the 2 X increase scenario. "In bounds" indicates the proportion of the simulation runs which indicated an increase from 1.5 times and 3.0 times the original biomass (within the red vertical lines). "Positive" indicates the proportion of runs which indicated a positive change in biomass (to the right of the vertical green line).

Using the doubling over 10 years scenario, the results appear congruent with our crude standard of using the survey RE's shown below to characterize the adequacy of the biennial survey, although we recommend using the $R E_{\text {OE,s,Pooled }}$.

- excellent $=\quad<0.20$
- good $=0.20-30$
- adequate $=0.30-0.40$
- poor $=0.40-0.60$
- very poor $=>0.60$

A biennial density of 240 tows is probably over-sampling for species like Dover sole, while providing poor indexing of canary rockfish and bocaccio. However, it would not be cost-effective to improve the indexing accuracy for these poor survey candidates by increasing the tow number.

It should be noted that these tables exaggerate the cost of improving the survey for any one population. The indexing of one population, especially one which tends to be confined to one depth stratum, could be improved by a relatively modest re-allocation of a few tows to a specific stratum. The intent of Table 10 is to show what would be required to simultaneously raise the precision of the survey for all of the poorly surveyed populations.

In the second set of scenarios, we examined the same populations given a $70 \%$ decline over 10 years with detection tolerance limits of 50 and $80 \%$ declines (Table 10,

Figure 21 and Figure 22). We again used $R E_{O E, s, P o o l e d .}$ The last column of Tables 10 and 11 were derived by re-running the simulator with different tow numbers until the desired accuracy was achieved.

Table 10. Summary of results in testing how well the GF-QCSd survey can track a $70 \%$ decline over 10 years using $R E_{O E, s, P o o l e d}$.

| Species | $R E_{\text {OE,s,Pooled }}$ | $R E_{\text {OEs,2005 }}$ | \% correct <br> within 0.2 and <br> 0.5 times |  | \% positive |
| :--- | :---: | :---: | ---: | ---: | ---: | | Approx. tows |
| :---: |
| required to be |
| correct $80 \%$ |

Figure 21. Simulation results for Dover sole under the $70 \%$ decrease scenario. "In bounds" indicates the proportion of the simulation runs which indicated a decrease from $20 \%$ to $50 \%$ (within the red vertical lines). "Positive" indicates the proportion of runs which indicated a positive change in biomass (to the right of the vertical green line).

Figure 22. Simulation results for canary rockfish under the $70 \%$ decrease scenario. "In bounds" indicates the proportion of the simulation runs which indicated a decrease from $20 \%$ to $50 \%$ (within the red vertical lines). "Positive" indicates the proportion of runs which indicated a positive change in biomass (to the right of the vertical green line).

We have created more contrast in the population change so the survey appears to perform better. For canary rockfish, the survey will almost always note the decline and even lead to estimating the correct amount of decline most of the time. Even for bocaccio, it noted a decline $90 \%$ of the time; although only a third of the time did it estimate the degree of decline correctly. Nevertheless, it continues to indicate that the adequacy of the survey for tracking a given species is represented by the simple qualitative classification of the $\mathrm{RE}_{\text {Pooled }} \mathrm{S}$ above, under the assumption of a biennial frequency. This in turn indicates that, while the accuracy of the survey will be disappointing for many species, it still provides adequate to excellent tracking for most of the species that are common in the catch, which includes most of the commercial species. Exceptions only include relatively rare animals and some of the rockfish, such as bocaccio and widow rockfish which have a very patchy distribution and low catchability to bottom trawl gear.

While the lack of precision for many species captured in the GF-QCSd survey is disappointing, we emphasize that one time series from this survey does not reflect the sum of the information that will be available at the time of assessment. These decisions will always be made with the knowledge that the index will be updated within two years. The survey data will also be only one component of the information available. Additional information will include age and size composition information from the survey and commercial fishery, commercial catch rates, as well as other surveys, both in BC and in US waters to the north and south.

## SURVEY COST OPTIMIZATION

## Analysis of Tow Number

It is appropriate after three years to re-examine whether the survey would be more cost-effective with a different number of tows. Table 11 shows the effect on the estimated $R E_{\text {Pooled }}$ of the 40 most precisely indexed populations of the survey. The number of tows is shown in 30 -tow increments. Adding 30 tows would add about $\$ 45 \mathrm{~K}$ to the cost of the survey.

Table 11. Estimated $R E_{\text {OE, }, \text {,Pooled }}$ for the 40 most precisely indexed populations at different tow densities. Net change is the average change in $R E_{\text {OE,S,Pooled }}$ across all species from the 240 tow configuration. Values are colour coded to correspond to levels of "accuracy" presented above.

| Net change | -22\% | -14\% | -7\% | 0 | 5\% | 7\% |

| Yellowmouth rockfish | 0.623 | 0.527 | 0.507 | 0.488 | 0.462 | 0.435 |
| Darkblotched rockfish | 0.633 | 0.564 | 0.539 | 0.515 | 0.473 | 0.423 |
| Big skate | 0.673 | 0.607 | 0.565 | 0.515 | 0.493 | 0.476 |
| W olf eel | 0.626 | 0.608 | 0.560 | 0.521 | 0.468 | 0.459 |
| Quillback rockfish | 0.718 | 0.628 | 0.578 | 0.549 | 0.527 | 0.512 |
| Widow rockfish | 0.845 | 0.721 | 0.668 | 0.600 | 0.591 | 0.546 |

We recommend continuing with 240 tows as the target. The marginal gain in precision by increasing to 270 and 300 appears negligible given the incremental costs of $\$ 45 \mathrm{~K}$ and $\$ 90 \mathrm{~K}$, respectively, while decreasing the tow number to 150 leads to an unacceptably large loss of $22 \%$ in precision.

The range of 180-240 appears adequate in the short term; however, we recommend over-sampling in anticipation of attrition in the sampling frame. As time passes, we expect more areas will become off-limits to the survey. Since we initiated the survey, the boundaries of the sponge reef closures have been altered, removing a few blocks that we fished in previous surveys. We can expect further attrition as closures are implemented to protect coral and/or other sensitive habitats. Analysts 20 years from now will probably choose to ignore the earlier tow data from blocks that were subsequently deleted from the sampling frame. Thus, we might expect that in the future, trend analyses may only be able to use $80-90 \%$ of the 2003-2005 data. If we wish future analysts to retain over 200 usable tows from present surveys, then we should continue to strive for 240.

Finally, the examples above treat all the species as one population in QCSd. Some of these species have been assessed as two populations within this area, for example Pacific ocean perch, canary rockfish, and silvergray rockfish. Assuming future assessments will continue this practice, the resulting indices will be based on half the tows. The precision of these indices will degrade more rapidly under lower overall survey densities.

## Analysis of Survey Frequency

Given the current cost structure and in today's dollars, we project that that the 240-tow survey conducted biennially will have a $10-y$ cost of $\$ 1,950 \mathrm{~K}$ (five surveys @ $\$ 390 \mathrm{~K}$ ). The simulator can be used to compare the effectiveness of the survey under different configurations for the same budget. In particular, we examined whether the survey would be more effective if done every year at a lower tow density under the same budget.

Based on our estimates of the fixed costs (cost to mobilize and demobilize for each survey) and the variable cost/tow of a lower density survey, we could conduct an annual survey of 95 tows for the same price as the current 240 -tow biennial configuration. Moving to an annual configuration is not cost neutral (120 tows/survey) because of the fixed costs of mounting a survey ( $@ \$ 30 \mathrm{~K} /$ survey ) and the fact that the cost/tow increases from ( $\approx \$ 1.5 \mathrm{~K}$ to $\$ 1.7 \mathrm{~K}$ ) as travel time between tows increases with the lower density (Figure 23).

Figure 23. Comparison of a 240 block allocation (a) and a 95 block allocation (b).

Table 12. Comparison of survey performance between 95 -tow annual and 240 -tow biennial surveys when abundance doubles over 10 years.

| Species | $R E_{\text {OE }, \text { s,Pooled }}$ | \% Correct within 1.5 and 3.0 <br> times | Tows required in annual <br> survey to match 240-tow <br> bi-ennial performance |  |
| :--- | :---: | :---: | :---: | :---: |
| Dover sole | Biennial (240) | Annual (95) |  |  |
| Arrowtooth flounder | 0.11 | 99 | 95 | 180 |
| Rougheye rockfish | 0.18 | 89 | 79 | 160 |
| Southern rock sole | 0.31 | 65 | 65 | 65 |
| Canary rockfish | 0.39 | 54 | 40 | 170 |
| Bocaccio | 0.51 | 42 | 34 | 150 |

From Table 12, it appears that, under a fixed budget, the biennial survey outperforms the annual configuration. This result, however, is conditional on whether $P E-C$ is included. The performance of the biennial survey degrades more rapidly than the annual survey as PE-C is increased (Figure 24). For arrowtooth flounder, the annual survey performs better if $P E-C$ is set at $>0.2$. For canary rockfish, the performances of the two configurations starts to converge at a $P E-C>0.4$. For Dover sole, they converge with a $P E-C=0.14$. This level of $P E-C$ appears to be greater than implied in Table 9. The average value of $P E-C$ across all species would have to be much larger than the generic value of 0.2 suggested by Francis et al. (2003).

Given our current understanding of the magnitude of PE-C for this survey and our cost analysis, it appears that the biennial configuration is more cost-effective than an annual approach.

Figure 24. Comparison of performance between 95 -tow annual and 240-tow biennial surveys with increasing process error. Performance is determined as the $\%$ of runs which indicate between a 1.5 X and 3.0 increase given an actual population doubling over 10 years.

We also examined whether a triennial survey would be more cost-effective (Table 13 and Figure 25). In this case we ran the doubling scenario over 12 years. Unlike the change from annual to biennial however, there is little reduction in cost/tow with a triennial survey. The density is already optimal with 240 tows, thus we expect little or no gain from reduced travel time. Furthermore, cumulative fixed costs only decline by one third as opposed to one half when changing from annual to biennial. Therefore, for the same price, we assume a gain of only about 10 tows/survey in the triennial configuration.

Table 13. Comparison of performance between 240 tow biennial and 370 tow triennial surveys when abundance doubles over 12 years.

| Species | $R E_{\text {OE,s,Pooled }}$ | \% Correct within 1.5 and 3.0 <br> times |  |
| :--- | :---: | :---: | :---: |
|  |  | Biennial 240 | Triennial 370 |
| Dover sole | 0.11 | 100 | 100 |
| Arrowtooth flounder | 0.18 | 90 | 93 |
| Rougheye rockfish | 0.31 | 68 | 74 |
| Southern rock sole | 0.39 | 55 | 61 |
| Canary rockfish | 0.51 | 45 | 49 |
| Bocaccio | 0.82 | 29 | 33 |

Figure 25. Comparison of performance between 240 -tow biennial and 370 -tow triennial surveys with increasing PE. Performance is determined as the $\%$ of runs which indicate between a 1.5 X and 3.0 increase given an actual doubling over 10 years.

The triennial survey performs modestly better, but is significantly more sensitive to PE-C (Figure 25). While it requires a PE-C of about 0.14 for Dover sole to render the annual and biennial configurations equally cost-effective, a $P E-C$ of 0.10 renders the
biennial and triennial surveys equally cost-effective. Similarly the "break even" PE-C for arrowtooth flounder declines from just over 0.2 to about 0.15 . These "break-even" values of $P E-C$ are approaching the implied values of Table 9 and, averaged over all species, the generic value of 0.2 of Francis et al. (2003).

Although the survey performance appears to improve modestly with a triennial frequency, we recommend continuing with the biennial design. The triennial survey is more sensitive to $P E-C$ which may be revealed to be larger than we currently estimate. A 3 -year frequency would also seem inadequate for managing dynamic species such as Pacific cod. It also means that biological samples will only be obtained every three years.

## ABUNDANCE TRENDS

With only three years of observations, limited use can be made of the survey results (Figure 26) although they have proved useful for inferring minimum biomass estimates for canary rockfish in a COSEWIC document (Stanley et al. 2005).

Figure 26. Estimated relative biomass from the 2003-2005 surveys of QCSd for selected rockfish species, $95 \%$ confidence limits are shown as red bars. Note: these values should be treated as minimum biomass estimates.

## BIOLOGICAL SAMPLING

The sampling target was to collect L/S samples for each species in each tow but we took two shortcuts to reduce the workload. First, we did not sample unless there were a minimum number of pieces per species (Appendix 2). Second, we choose to sample only some of the tows for those species which were present in most of the tows. For example, since arrowtooth flounder are caught in $88 \%$ of the tows, we felt that sampling this species every third tow would yield a sufficient number of samples. Thus, our goal is to rationalize our sampling efforts in order to achieve adequate sample sizes for as many species as possible (Table 14).

To examine whether we were attaining our sampling protocol, we created a simulator that calculated from the catches in the survey how many samples we should have obtained if the protocol were followed perfectly (Table 15 to Table 17).

The simulator first converts species weights in each tow to numbers using a mean weight by species table. The catch in numbers for each species in each tow is then compared against the sampling protocol to predict the species whether the species would have been sampled in that tow, given perfect decision-making by the deck boss. The sum of these opportunities over all tows represents the predicted number of samples. The predicted piece count obtained from each of the predicted samples was determined as the number of pieces in the catch up to the maximum piece count per sample specified in the protocol.

The results indicate that the sampling protocol has been followed and that the number of samples obtained is meeting our expectations. We suggest that sampling effort does not have to be increased and the survey can forgo the additional 15 K in cost for one more sampler, but we could not achieve the protocol with any fewer staff.

Table 14. Numbers of samples ( n ) and specimens (N) by sample type and species from the 2005 QCSd survey.

## RECOMMENDATIONS

1. The survey should be continued.
2. The survey should continue with a target of 240 tows and a biennial frequency. The next RFP will be jointly developed with CGRCS in the spring of 2007.
3. The current stratification is acceptable but should be re-examined prior to the 2009 survey given the declining cost/risk of shallow tows.
4. Previously rejected blocks should be permanently eliminated from the sampling frame.
5. Prior to the next survey, trawl skippers should be consulted to identify any additional blocks which are sure to be untrawlable. These should be permanently removed from the sampling frame.
6. A scientific crew of five is adequate to meet the biological sampling needs.
7. The survey simulator will be used to examine the power of the other groundfish indexing surveys. We will assume that a biennial frequency is optimal for the major bottom trawl surveys.
8. The tow densities of the other surveys will be tailored to meet the RE standards accepted for the GF-QCSd survey.
9. We will use the simulator to see if the West Coast Vancouver Island thornyhead survey can be merged into the biennial WCVI shelf survey on the CCGS W.E. Ricker.
10. The general operational procedures for the GF-QCSd survey, such as requiring only a single rejection to delete a block, should be adopted for the other major bottom trawl surveys.
11. The current sampling protocol is acceptable, notwithstanding minor modifications or re-prioritizing among sampled populations.

## APPENDIX 2. BIOLOGICAL SAMPLING PROTOCOL

Fishing and sampling follow the prioritization of:

1. do not let sampling get in the way of fishing and sorting the catches;
2. do not let otolith samples get in the way of $\mathrm{L} / \mathrm{S}$ and $\mathrm{L} / \mathrm{S} / \mathrm{W}$ samples;
3. obtain at least two $\mathrm{L} / \mathrm{S} / \mathrm{W}$ samples per species/stratum for dominant species.

The objective of biological sampling during these surveys is to develop relative indices of species numbers (abundance), numbers at length, numbers by sex (when required), and numbers at age. These indices will complement the index of species biomass already described. We therefore collect length by sex data from all species caught in every tow, with two exceptions. First, the number of specimens caught must meet the minimum criterion for that species (Appendix 2: Table 1). Second, some species occur so frequently that we will collect a length/sex sample every second or third tow. In addition, one length/sex/weight (LSW) and one length/sex/weight/maturity/age (LSWMA) sample is collected per tow with the objectives of collecting two LSW samples per species per depth strata and 300 LSWMA specimens from each of the major commercial species. LSWMA samples are by default LSW samples in the overall scheme. For each set, the commercial species with the largest catch, if greater than 40 pieces, is sampled, to a target of 300 age structures per stock. In addition, the following species are sampled for age structures on every tow if minimum sample size requirement is met:

| Species | Minimum Sample Size |
| :--- | :---: |
| Pacific cod | 10 |
| Rock sole | 10 |
| Petrale sole | 10 |
| Lingcod | 10 |
| Redbanded rockfish | 5 |
| Bocaccio | 1 |
| Copper rockfish | 1 |
| Darkblothed rockfish | 1 |
| Quilback rockfish | 1 |
| Shortraker rockfish | 1 |
| Yelloweye rockfish | 1 |

Age structure sampling was based on random collections. There was no attempt to stratify by sex or size.

Appendix 2: Table 1. A partial list of the minimum specimen criteria and sampling frequency which sets a maximum of $60 \mathrm{~L} / \mathrm{S}$ samples per survey per species.

| Species | Occurrences <br> in 2003 | Sampling <br> frequency <br> per tow | Minimum <br> number of <br> specimens in <br> catch |
| :--- | :---: | :---: | :---: |
| Arrowtooth flounder | 213 | 3 | 10 |
| Rex sole | 201 | 3 | 10 |
| Pacific ocean perch | 181 | 2 | 10 |
| Dover sole | 172 | 2 | 10 |
| Spotted ratfish | 151 | 2 | 10 |
| Sablefish | 135 | 2 | 5 |
| Redbanded rockfish | 129 | 1 | 1 |
| Silvergrey rockfish | 127 | 1 | 5 |
| Spiny dogfish | 126 | 1 | 1 |
| Shortspine thornyhead | 106 | 1 | 1 |
| Pacific cod | 105 | 1 | 5 |
| Slender sole | 95 | 1 | 10 |
| Walleye pollock | 92 | 1 | 5 |

|  |  |  |  |

## APPENDIX 3. CALCULATION OF RELATIVE CATCH RATE AND RELATIVE ERROR

The area covered by each tow (swept area) was calculated as the mean doorspread (the distance between the trawl doors) multiplied by the distance that the vessel traveled during the tow. Doorspread measures were obtained electronically from sensors and were recorded throughout each tow at one second intervals. The distance traveled during each tow was determined by multiplying the mean vessel speed during the tow by the duration of the tow. The tow duration is defined as the interval between the net-onbottom start time and the net-on-bottom end time, as determined by a bottom contact sensor.

The expanded swept area catch rates were obtained by summing the product of the CPUE and the area surveyed across the surveyed strata $i$ for each species $s$ as before (Appendix 1 of Stanley et al. 2004) for each year separately.

$$
\begin{equation*}
B_{s}=\sum_{i} C_{s_{i}} A_{i}=\sum_{i} B_{s_{i}} \tag{Eq. 1}
\end{equation*}
$$

where $\quad C_{s_{i}} \quad=$ mean CPUE density $\left(\mathrm{kg} / \mathrm{km}^{2}\right)$ for species $s$ in stratum $i$
$A_{i} \quad=$ area of stratum $i\left(\mathrm{~km}^{2}\right)$, and
$B_{s_{i}} \quad=$ estimated biomass of species $s$ in stratum $i$.
The variance of the survey biomass estimate $V_{B_{s}}$ for species $s$ is calculated in $\mathrm{kg}^{2}$ as follows:

$$
\begin{equation*}
V_{B_{s}}=\sum_{i} \sigma_{s_{i}}^{2} A_{i}^{2} / n_{i} \tag{Eq. 2}
\end{equation*}
$$

where $\quad \sigma_{s_{i}}^{2} \quad=$ variance of CPUE $\left(\mathrm{kg}^{2} / \mathrm{km}^{4}\right)$ for species $s$ in stratum $i$
$n_{i} \quad=$ number of tows in stratum $i$
CPUE $\left(C_{s_{i}}\right)$ was calculated as a density in $\mathrm{kg} / \mathrm{km}^{2}$ by

$$
C_{s_{i}}=\frac{\sum_{j=1}^{n_{i}}\left(W_{s_{i} j} / D_{i j} w_{i j}\right)}{n_{i}}
$$

Eq. 3
where $\quad W_{s_{i} j}=$ catch weight $(\mathrm{kg})$ for species $s$ in stratum $i$ and tow $j$
$D_{i j} \quad=$ distance travelled (km; average speed multiplied by tow

$$
\begin{array}{ll} 
& \text { duration) by tow } j \text { in stratum } I \\
w_{i j} & =\text { doorspread width }(\mathrm{km}) \text { for tow } j \text { in stratum } i \\
n_{i} & =\text { number of tows for stratum } i
\end{array}
$$

The relative error (RE) for each species $s$ was calculated as follows:

$$
\begin{equation*}
R E_{s}=\frac{\sqrt{V_{B_{s}}}}{B_{s}} \tag{Eq. 4}
\end{equation*}
$$

One thousand bootstrap replicates with replacement were made on the survey data to estimate bias corrected $95 \%$ confidence regions for each survey species (Efron 1982). In the document we refer to this estimate of the variance at the RE based on observational error for population $s$ and year $y\left(R E_{O E, s, y}\right)$.

We also calculated a "Pooled" estimate ( $R E_{\text {OE,s,Pooled }}$ ) using the first three years of the data. The calculation was as above, except we combined all three years of data as if it were one survey. The intent of this estimate of the variance is to implicitly incorporate the among year Process Error (PE-C) owing to changes in catchability over the three years to provide a more realistic estimate the precision of the survey, since this is underestimated by using only Observation Error. The weakness of this approach is that it also implicitly includes the Process Error ( $P E-A$ ) owing to real changes in abundance, thus possibly overestimating the true survey variance.

## APPENDIX 4. THE SURVEY SIMULATOR

The survey simulator is based on a simulation model developed by Schnute and Haigh (2003) to assist in the planning and design of groundfish surveys. We extend their model to simulate the trend in future abundance, provide options for specifying the variance of positive tows, and provide a convenient graphical front-end for controlling the simulation (Appendix 4: Figure 1).

Figure 1. Graphical front-end for the simulator.
Annual stock growth is simulated using a compound annual growth rate given as:

$$
\left[\frac{B_{t}}{B_{t_{0}}}\right]^{\frac{1}{t-t_{0}}}-1
$$

where $B_{t_{0}}$ is the starting biomass and $B_{t}$ is the biomass after $t$ years.
We provide three options for specifying the variance of positive tows, which is used as a parameter for the gamma distribution (see Schnute and Haigh, 2003). These are:

1. Use the observed variance from a single year of the survey (2003-2005).
2. Use the observed variance from all three survey years pooled.
3. Use (1) or (2) above, plus a specified amount of additional process error.

In general terms, the catch for each stratum for a given species is estimated from the observed data in terms of the mean and variance of non-zero tows and the proportion of zero catches $(\mu, v, p)$. These parameters define a theoretical distribution of catches from each stratum of the survey. For the starting year, the simulator draws $n=240$ results, for example, (with specified allocation by stratum) from the theoretical distributions to generate one survey result for year 0 . This is converted to one survey index point for year 0 as described above. This process is repeated 5,000 times to create an observed set of possible survey results for year 0 . The same process is repeated for the subsequent survey ( +2 years) after incrementing the population according to the specified growth rate. [Note: for this report, the population change was mediated by increasing the catch in non-zero tows; we did not vary the proportion of zero tows].

Option 2 above simply combines all 720 tows into the initial data set, prior to calculation of the variance parameters. For most species, it increased the estimates of variance owing to the addition of $P E$ over the three surveys.

Option 3, is similar to Option 1 and uses the variance calculated from only one survey year. Process error is added by "jittering" (multiplying) each of the 5000 survey results by a random normal deviate with a mean of 0 and standard deviation specified in the simulator front end (Appendix 4: Figure 2). One simulated time period of surveys is simply the result of pulling one index value from each of the simulated survey years.

Figure 2. Comparison of simulated survey indices before (blue boxplots) and after (yellow boxplots) the addition of a user-specified process error. The upper and lower edge of each box define the first and third quartiles of the data, respectively, with the central bar representing the median. The "whiskers" extending from each box are drawn to the most extreme data point that lies within 1.5 times the inter-quartile range; any points outside this limit are shown as individual points and are considered as outliers.

# APPENDIX 5. LIST OF RE'S FOR ALL FISH SPECIES IN THE GFQCSD SURVE ${ }^{3}$. 

| Species | 2003 | 2004 | 2005 | Average | Pooled | Species | 2003 | 2004 | 2005 | Average | Pooled |

Table 2. List of Survey acronyms used in Appendix 1. Table 1

| Survey Name | Surveys (survey number from Appendix 1) |
| :--- | :--- |
| QCSBT | Queen Charlotte Sound bottom trawl survey (3) |
| QCSBTN | Queen Charlotte Sound bottom trawl survey (3) - north stratum |
| QCSBTS | Queen Charlotte Sound bottom trawl survey (3) - south stratum |
| WCVIBT | West coast Vancouver Island bottom trawl survey (4) |
| HSBT | Hecate Strait bottom trawl survey(2) |
| WCQCIBT | West coast Queen Charlotte Islands bottom trawl survey (1) |
| WCVISH | West coast Vancouver Island shrimp bottom trawl survey (10) |
| QCSSH | Queen Charlotte Sound shrimp bottom trawl survey (10) |
| WCVITH | West coast Vancouver Island thornyhead bottom trawl survey (5) |
| IPHCLL | IPHC longline survey (11) |
| JSLL | Johnstone Strait longline survey (12-13) |
| LCYOY | Strait of Georgia lingcod young-of-year bottom trawl survey (15) |
| PHMALL | PHMA near-shore longline survey (6 and 7) |
| IPHCVN | IPHC longline survey - Vancouver Island station (11) |
| IPHCGJ | IPHC longline survey - Goose Island and Cape St. James stations (11) |
| IPHCCH | IPHC longline survey - Queen Charlotte Islands Stations (11) |

Table 3. Ranked list of all available groundfish survey RE's for each species/population.

| Species | Stock |  |  |  |  |  |  |  |  |  |

[^0]:    ${ }^{1}$ The fraction of a fish stock which is caught by a defined unit of fishing effort (Ricker 1975).

[^1]:    ${ }^{2}$ Note: "First year" indicates first year of relatively frequent series of surveys

[^2]:    ${ }^{3}$ Relative errors are colour coded corresponding to qualitative classes of accuracy shown above.
