Abstract

The report provides statistics on occupational radiation exposures for use by regulatory authorities, organizations and private individuals. Out of a total of 134,267 monitored workers, 18 annual doses exceeded the regulatory limit of 50 mSv in 2001. This is substantially more than in previous years; however, 13 of these exposures occurred at the same employer, suggesting a common source of the exposures. Out of 58 specified job categories, 26 had a smaller annual average in 2001 than in 2000, 28 had a higher average, and 4 had the same average rounded to 0.01 mSv. Most of the decreases in average dose occurred in the uranium mines, where the averages may be underestimated because not all data were collected at the time of data extraction for the report. Thus, there may be a small overall increase in dose. It is too early to speculate whether this will be a continuing trend.

Acknowledgements

This document was prepared by Dr. W. Sont and Dr. J.P. Ashmore of the Occupational Radiation Hazards Division, Radiation Protection Bureau.

Acknowledgements are extended to Mrs. C. Powell, Mrs. Y. Huang, and Mr. B. Davies for their assistance.

Appendix

The lognormal and hybrid lognormal distributions 73

Introduction

This series of reports provides statistics on occupational radiation exposures of monitored workers in Canada. The statistics are intended to assist regulatory authorities, organizations, and private individuals in comparing incurred occupational radiation exposures with national or provincial/territorial averages and trends in similar occupations. Previous issues of the report can be obtained from the authors⁽¹⁻⁵⁾.

The information is based on the data in the National Dose Registry (NDR) maintained by the Radiation Protection Bureau of Health Canada⁽⁶⁾. The Registry is a centralized record-keeping system containing dose information on all monitored workers in Canada. It includes data submitted by nuclear power generating stations, Atomic Energy of Canada Ltd., uranium mines, and dosimeter processing companies.

Information for input into the NDR is received either via a direct link or by mail in computer readable form.

The report provides data on the two consecutive years prior to the year in which the data are extracted from the database. The data for the second (i.e. more recent) year will be close to stable at the time of data extraction. Some changes may still occur, for which the most frequent causes are: (1) a high dose to a dosimeter is judged to be non-personal after investigation; (2) a job category of a worker is updated; or, (3) dosimeters or data are returned late. The report therefore contains preliminary data on the second year (Table 1), and more complete data on the first year (Tables 2-4).

For a description and a guide to interpretation of the data, the reader is referred to the next section "General comments". The section "Comments specific to this report" has been included to address situations that do not recur from year to year.

General Comments

The statistics include doses as they exist in the database at the time they are extracted for analysis, which in the case of this report is August 10, 2002. Doses are assigned to the year in which the dosimeter was issued, even though some of the dosimeters may actually have been worn during part of the subsequent year. As the statistics are determined in the same manner each year, the annual dose figures are based on a 12-month period, though not necessarily the strict calendar year.

Dose records submitted by outside organizations such as nuclear power generating stations, uranium mines, and commercial processors, are included to the extent that they have been received. The doses are representative of the calendar year only if the fourth quarter records have been received by the time of analysis. When statistics are based on partial data, the fact is indicated in the section "Comments specific to this report".

All doses are in International System (SI) units and presented to the nearest hundredth of a millisievert (1 mSv = 100 mrem). For the external whole body doses various organizations have set recording thresholds from 0 to 0.2 mSv.

The words "dose" and "exposure" are used interchangeably in this report. Doses of different types of radiation are expressed in mSv and added to give the effective dose stated in the report. The following dose types may be included:

- External whole body gamma.
- External whole body high energy beta.
- External whole body X-ray.
- External whole body neutron.
- Internal whole body tritium, as determined by urinalysis.
- Radon progeny exposures, converted from WLM values (see below).

All types of exposure are given in one total. In Tables 3 and 4, the percentage contribution of radon progeny and tritium components are indicated for occupations related to mining and nuclear power generation, respectively. Skin doses and extremity doses are not included in the report but are recorded in the database.

In the NDR database, radon progeny exposures are expressed in Working Level Months (WLM), which are in most cases calculated by the mines on the basis of area monitoring⁽⁷⁾. In the report the radon progeny exposures are converted to equivalent doses (in mSv). The value used in this report is 5 mSv/WLM, in accordance with the radiation protection regulations⁽⁸⁾ under the Nuclear Safety and Control Act, which came into force on May 31, 2000.

Job category designations are based on a standard list provided by the Registry and are updated when the Registry is notified. The job category is selected by the organization from a standard list maintained by the NDR. The NDR keeps the most recent job category that an organization submits for a worker in a given year. However, a worker who has been monitored by more than one organization, can have records under more than one job category for the same year. Some organizations have their own job classifications schemes, and translate them into the Registry's standardized list prior to submission of the records.

In this report, the data are tabulated as follows:

2001: Preliminary analysis

Table 1:

Table 1 gives the annual dose distributions by job category.

2000: Final Analysis

Table 2:

Table 2 contains dose statistics by job category and province or territory.

Table 3:

Table 3 contains dose statistics by age and sex. In this table job categories have been grouped into "job sectors".

Table 4:

Table 4 contains various dose statistics by job category. The table also shows the parameters of the lognormal or hybrid lognormal distribution for positive doses, as produced by maximum likelihood estimation. From that information, it is possible to calculate estimates and confidence intervals of statistics of the distribution. For a more detailed discussion the reader is referred to the Appendix.

Table 4 also includes an accumulated dose distribution over the 5 year period 1996-2000 for the workers under the given job category.

Finally, Table 4 contains a histogram that shows the trend in average annual doses over the period 1991-2000.

It should be noted that in the tables, a worker is counted more than once if he (she) works in more than one job category, in more than one province, or in more than one job sector in the same year. For this reason the totals in Tables 2-4 may slightly differ.

Comments specific to this report

Not all data on exposures in uranium mines were collected at the time of extracting data for the report. As a consequence some annual doses may be underestimated.

Many previously unreported job class codes are now being reported and have been copied to previous years at the same organization. This has impacted particularly on the graphs in Table 4. For example, the average dose of safety officers for 1999 has increased from 0.06 mSv in the 2001 report to 0.22 mSv in this report. This is because of a high dose associated with an unknown job class in the 1999 report, which job class has since been reported as safety officer.

Appendix

The lognormal and hybrid lognormal distributions

The appendix explains how the data can be fitted to a statistical distribution, so that: (1) the sample of doses can be described by 3 or 4 quantities (the parameters of the distribution and sample size); and, (2) from these quantities, any dose statistic can be estimated, including any statistic not listed in this report, such as the 9-th decile.

Statistical distributions, such as the lognormal or hybrid lognormal distribution, are defined by a probability density function, containing a variable x , which in our case represents the occupational dose. This function is interpreted as follows:

The probability that a dose value lies between a and b equals

$$\int_a^b f(x)dx$$

where f represents the probability density function.

Besides the variable (occupational dose) the probability density function contains a number of parameters, which determine the shape of the function. Only when the parameters have been specified is the statistical model for the occupational dose defined. Parameters are adjusted to fit the data.

The lognormal probability density function f is given by:

$$f(x; \mu, \sigma^2) = (1/x)(2\pi\sigma^2)^{-1/2} \exp(-\ln(x)-\mu)^2/2\sigma^2$$

The hybrid lognormal probability density function f is given by:

$$f(x; \rho, \mu, \sigma^2) = (\rho+1/x)(2\pi\sigma^2)^{-1/2} \exp(-\ln(\rho x)+\rho x-\mu)^2/2\sigma^2$$

In these functions, the quantities μ and σ^2 are parameters of the distribution. The hybrid lognormal distribution contains an extra parameter ρ . This distribution was introduced by Kumazawa⁹ *et al*, for the purpose of describing a workforce that makes a sustained effort to stay below a regulatory limit.

This distribution often gives a better fit than the lognormal distribution for certain high dose occupations, such as nuclear medicine workers. It is similar to a lognormal distribution for low doses and to a normal distribution for high doses.

If the parameters for the probability density function f are known, one can estimate any dose statistic. For example, the mean dose is estimated as

$$\int_0^\infty xf(x)dx$$

(since the dose values x are between 0 and infinity).

The variance of the dose is estimated as:

$$\int_0^\infty (x-\text{mean})^2f(x)dx$$

and the standard deviation as the square root thereof.

The probability that a dose exceeds, for example, 50 mSv, is estimated as:

$$\int_{50}^\infty f(x)dx$$

The 95-th percentile is estimated as that dose value v for which:

$$\int_v^\infty f(x)dx = 95/100$$

The fraction of the collective dose due to doses exceeding 15 mSv is estimated as:

$$\frac{\int_{15}^\infty xf(x)dx}{\int_0^\infty xf(x)dx}$$

The parameters are determined from the actual dose data. They are chosen to give the best "fit" with the sample of observed data, for which purpose there exists a variety of methods. The parameters in Table 4 have been estimated with the Maximum Likelihood method. With this method, dose statistics can be estimated with the formulas given above, with the tabulated parameter values substituted for (ρ), μ , and σ^2 .

Software is available from the authors for the purpose of estimating occupational dose statistics and their confidence intervals. Since the lognormal and hybrid lognormal distribution do not apply to zero doses, as evident from the formulas of their probability density functions, the software will determine parameters based on positive doses only. Estimates for the total of all doses can be derived if the numbers of zero and positive doses in the sample are taken into account. For example, consider a sample in which half the doses are zero. If the parametric estimate is 2 mSv for the mean of the positive doses, then the estimate of the mean of all doses is 1 mSv. Or, if a parametric estimate for the 95-th percentile of all doses is needed, it is calculated as the estimate of the 90-th percentile for the positive doses.
