ABSTRACT

Beamish, R. J., M. S. Smith, V. Egan, D. Brown, and G. McFarlane. 1981.
Results of spiny dogfish (Squalus acanthias) tagging in the Strait of Georgia in 1979. Can. Data Rep. Fish. Aquat. Sci. 262: 73 p.

A total of 4,542 dogfish were tagged and released in the Strait of Georgia in 1979. Petersen disc tags were used to tag 3,214 fish and a modified design of the Petersen disc to tag 1,328 fish. Forty-one live dogfish were transported from Campbell River to the Pacific Biological Station for a study of tag performance and fish mortality.

Key words: Spiny dogfish, tagging, Strait of Georgia.

RÉSUMÉ

Beamish, R. J., M. S. Smith, V. Egan, D. Brown, and G. McFarlane. 1981.
Results of spiny dogfish (Squalus acanthias) tagging in the Strait of Georgia in 1979. Can. Data Rep. Fish. Aquat. Sci. 262: 73 p.

Un total de 4542 aiguillats ont été étiquetés et relâchés dans le détroit de Géorgie en 1979. Pour 3214 poissons, on a utilisé le disque de Peterson tandis que pour les 1328 autres, on s'est servi d'une version modifiée du disque. Quarante et un aiguillats vivants ont été transportés de la rivière Campbell à la Station de biologie du Pacifique de façon que l'on puisse étudier le résultat de l'étiquetage et la mortalité des poissons.

Mots clés: Aiguillat, étiquetage, détroit de Géorgie.

INTRODUCTION

This is the second report of the dogfish tagging program carried out in the Strait of Georgia as part of a cooperative effort between students and staff of Campbell River Senior Secondary School, Southgate Secondary School, and staff of the Groundfish Program at the Pacific Biological Station, Nanaimo. The first report was published as Fisheries and Marine Service Data Report No. 141, and summarized the 1978 results. The primary objective in 1979 remained unchanged, namely, to examine growth and movements of dogfish in the Strait of Georgia. In addition, as part of a study to develop a long-term tag for dogfish, 1,328 fish were tagged with a modified Petersen disc.

A summary of 1978 tag returns for 1979 is also included in this report.

MATERIALS AND METHODS

Tagging was concentrated in three main areas; the Campbell River area, the Central Strait area off Sechelt Peninsula and Lasqueti Island; and the Gulf Islands area off Valdes Island (Detwiller Point).

Tagging in the Campbell River area was carried out by staff and students from Campbell River School District and staff of the Pacific Biological Station, while tagging in the other areas was carried out by staff of the Biological Station alone.

Dogfish were caught on a longline anchored to the bottom in depths that varied from 9-113 m in the Campbell River area and 100-183 m in the central Strait-Valdes Island areas. The "soak" time varied between sets, soak time being defined as the time between the first hook going overboard as the longline goes out and the first hook coming aboard on the retrieve. The range of soak times was 40-95 min in the Campbell River area sets and 90-225 min in other area sets. Retrieval always began at the end of the line that was set first.

Seven modifications were introduced in the 1979 Campbell River program: (1) hooks were all the same size; (2) barbs were pinched down with pliers on all hooks used; (3) dogfish were anesthetized prior to measurement and tagging; (4) some fish were randomly selected and re-measured to check on accuracy of measurements; (5) forty-one dogfish were transported to the Pacific Biological Station from the tagging area for studies on tag performance and fish mortality; (6) a greater effort was made to handle fish carefully; and (7) the amount of bleeding and behaviour of fish was noted upon release.

The type of hook used was a "Mustad" No. 2 halibut hook quality 9401 with 3.3-mm diameter wire, 93 mm from the tip of the eye to the base of the hook and 30 mm from the front of the shaft to the tip of the hook (gape). This was the same hook used in 1978 referred to as the larger hook in the hook size experiment (Brown et al. 1979). All hooks were fastened on gangions approximately 55 cm long which were snapped on the longline about 2 m apart as the line was set. Thawed herring chunks were used as bait in all sets.

Tagging in the Campbell River area was carried out by student teams under the guidance of a teacher. On each tagging day, eight students and one teacher went aboard the commercial fishing vessel INVADER I. Two teams of three students measured, sexed, and tagged dogfish and recorded data; one student handled fish, taking them from the commercial fisherman at the stern and putting them into a fiberglass tank containing approximately 150 L of water to which had been added 25 g of the anaesthetic tricaine methane sulfonate (MS222). The dogfish were kept in the anesthetic until they showed signs of lethargy and then passed to one of the two tagging teams. One student recorded hook data at the stern as the longline came in.

Measurements were made by placing the dogfish in a wood measuring trough equipped with a meter stick in the bottom. Each fish was measured from the tip of the snout to the tip of the upper lobe of the caudal fin when depressed in a line horizontal with the body. Measurements were made to the nearest cm. Remeasurements were made on 27 fish selected randomly from 6 sets to establish the accuracy of measurements taken. Tagging and data collection procedures were similar for other areas except that the whole operation was handled by 1 three-man team aboard the commercial fishing vessel OCEAN VIKING.

A pair of Petersen discs was attached to each dogfish in the Campbell River area and modified Petersen discs to each fish captured at other sites. The Petersen disc tags were bright yellow with the following message: (Side 1) REWARD Pac. Biological Station, Nanaimo, B.C. Canada DF410000. (Side 2) FREEZE FISH NOTE WHEN AND WHERE CAUGHT CALL COLLECT (604) 758-5202. Two discs, one on each side of the dogfish, were placed just below the anterior base of the first dorsal fin and fastened with a titanium wire that was secured on each side by bending the wire 180° to form a small circle, with the free end of the wire resting under the portion of the wire that projected from the hole in the disc (Fig. 1). The importance of establishing the correct amount of tension on the discs is noted under "Results and Discussion". The modified Petersen discs are a pair of plastic plates which are elongate in shape, measuring 6.5 by 19.3 mm and 1.1 mm thick (Fig. 2). A hole is drilled through each tag 2.5 mm from each end. The plates are attached by two titanium wires using the same procedures described for the Petersen discs. Each modified design carried basically the same message as the Petersen discs except that part of the caption i.e. "FREEZE FISH" was inadvertently left out. Dogfish captured in the first five sets off Valdes Island were tagged using 7.6-cm titanium pins which were inserted in the same manner as the wire but required looping the pin on only 1 side.

Data recorded for each fish included the tag number, sex, length, condition of hook wound and the amount of bleeding. The hook wound and

amount of bleeding were recorded as being slight (S), moderate (M), or excessive (E). Notes were kept on the condition of fish when released, whether they dived out of sight, or showed signs of other problems such as balance, swimming aimlessly on surface, etc. (Appendix Table 1).

Forty-one fish were tagged and transported to the Pacific Biological Station between May 9 and 16, 1979 for a study of tag performance and fish mortality. All fish were tagged and transported on the day of capture; 15 on May 9, 5 on May 14, and 21 on May 16 and all were assessed as to hook wound and amount of bleeding.

As part of the publicity campaign, "TAGGED DOGFISH" posters, identical to those used in 1978 were given wide distribution. Posters were maintained in marinas, government docks, major fishing companies, and were again sent to the B.C. Ministry of Environment and 2 fishing agencies in western Washington. Letters describing the study were sent to all fishermen who were likely to come in contact with tagged dogfish.

RESULTS AND DISCUSSION

Between April 23 and May 18, 1979 and November 26-30, 1979 a total of 4,542 dogfish were tagged of which 3,214 were tagged with Petersen discs (Fig. 1a, b) and 1,328 with a modified Petersen disc design (Fig. 2a, b). Locations of tagging sites are indicated by the triangles in Fig. 3. Of the fish tagged with Petersen discs, 1,822 were tagged at Marina Island, 196 at Smelt Bay, 855 at Cape Mudge Reef and 336 at Oyster Bay, respectively. Of the fish tagged with the modified design, 88 were tagged at Detwiller Point, 337 south of Thrasher Rock, 300 off the Sechelt Peninsula, and 603 north of Lasqueti Island. All 88 fish tagged off Detwiller Point and the first 310 fish tagged south of Thrasher Rock were tagged using 7.6-cm titanium pins specially manufactured for this program. The location of the sets, and information regarding tags and catch data are included in Tables 1, 2, 3, and 4. Species caught incidentally during the study are presented in Table 5.

Dogfish ranged in length from 43-118 cm (Tables 6-11; Fig. 4a, b, 5). Males ranged in length from 46-103 cm with a mean size of 79 cm and females ranged in lengths from 43-118 cm with a mean length of 86 cm. A total of 2,215 males (49%) and 2,324 females (51%) were tagged, (4 unknowns). Females predominated in the Marina Island/Smelt Bay location (63%). This compared to 79% females in the same area in 1978. However, males predominated in the Oyster Bay area, 68%, which was similar to the 70% males in 1978. In the Cape Mudge Reef sets, predominantly males (80%) were captured (Table 8). Females predominated in the catch off Valdes Island and Sechelt Peninsula, 76% and 89%, respectively. Males predominated (68%) in the catches north of Lasqueti Island (Table 11).

Eighty-three percent of the males and 73% of the females in all areas were equal to or larger than the minimum commercial length of 71 cm in 1979.

Catch per unit effort (C.P.U.E.) varied between 126 and 292 dogfish per 1000 hooks for areas fished (Table 12). The C.P.U.E. for dogfish larger than the commercial size limit (71 cm) also varied, with the majority of smaller fish being tagged in the Campbell River area (Table 12).

The average time required to set and haul one complete set of gear was 152 min (Tables 1, 2) an average of 125 min for Campbell River sets and 178 min for other area sets.

A total of 979 hooks (5%) caught species other than dogfish. Sunflower star was the incidental species most often captured (Table 5).

RECAPTURES

A total of 32 dogfish tagged during 1979 were recaptured prior to December 31, 1979, all from the spring tagging study in the Campbell River area. Sixteen fish were recaptured in the Strait of Georgia, 3 in Juan de Fuca Strait, 1 north of Cape Scott and 9 were recaptured north of the tagging area. Three fish were recovered in the processing plant and recovery location is not known (Fig. 3). Two other recaptures were reported but no corroborating information (tags not returned to Biological Station) was received. Twelve fish were recaptured by longline, 11 by trawl, 2 by salmon gillnet, 1 by troll, and 3 by sports fisheries. Whole fish were returned in 20 instances, however 1 of these returns had no recapture information.

The longest net distance travelled was 272 km and the maximum time at large for 1979 was 230 days, (Table 13). All whole fish returned were larger than the minimum commercial size limit. Of the 12 recaptures for which only tags were returned 8 were larger than the commercial size limit at time of release.

An additional 15 dogfish tagged in 1978 with both Petersen discs and Fløy anchor tags were recaptured in 1979 (Fig. 6; Table 14). One tagged dogfish recovery was reported but not confirmed. A description of the tags and tagging procedure in that year appears in Brown et al. (1979). Six individuals were recaptured by longline, 3 by salmon gillnet, 3 by sports fisheries, 2 by trawl, and 1 by jigging. Whole fish were returned in 10 of the recaptures and anchor tags were absent from 8 of these fish. Anchor tags were absent from all 5 of the recoveries where complete information, but not the whole fish, was provided.

The longest net distance travelled was 207 km and the maximum time at large for these fish was 558 days (Table 14). Eight of the whole fish returned were larger than the minimum commercial size limit. Of the 5 recaptures for which only tags were returned 3 were larger than the commercial size limit at the time of release.

All whole fish returned were examined for tag wounds. There was no obvious damage to the disc or the wire pins, however, where the disc appeared to have been loosely attached the edge had worn completely through

the skin, (Fig. 7). The open wounds did not appear to be infected. Growth of algae occurred on most tags.

Of the 41 fish transported to the Pacific Biological Station between May 9 and 16, 1979 for a study of tag retention and fish mortality, 10 had died as of December 31, 1979. There was no relationship between the condition rating ascribed to the fish at the time of tagging and death (Table 16). Of the 10 dead fish 2 had been noted as having excessive wounding, 2 as moderate, and 6 as slight. Although the fish mortality study is continuing, preliminary results have shown that only 3 of the deaths, i.e. those fish that died within 3 weeks of capture, could be attributed to injury at time of capture or subsequent handling of the fish. The remaining 7 deaths occurred between 4 and 8 mo. of capture and though no conclusions can be drawn as yet the culture problems associated with keeping dogfish are not new (Jones and Geen 1976). Of the fish remaining in the tank at time of writing, all hook wounds had healed and all fish were actively swimming and feeding (Fig. 8). As fish in the tank showed signs of abrasion caused by the Petersen discs, similar to the wounds observed on recaptured fish (Fig. 7), these discs were removed and the fish were retagged using the modified Petersen design.

Brown et al. (1979) indicated an error of +2 cm when measuring unanesthetized fish. In this study the random sampling of fish for remeasurement indicated that anesthetizing appeared to reduce the estimated error in measurement. Of the 32 fish selected for remeasurement, 21 showed no change, 5 were +1 and 2 were -1 cm, 1 was +2 and 1 was -2 cm (Table 15).

Since dogfish are believed to live to ages in excess of 60 yr (Wood et al. 1979), the observations of growth and movement during the first few years following tagging may not be representative of the results over the life of individual dogfish.

ACKNOWLEDGMENTS

This study was intended to provide scientific information to aid in the management of dogfish stocks as well as allow high school students to participate in the planning, execution and analysis of a practical biological research problem. The success of this study is a direct result of the participation and enthusiasm of the students of Campbell River Secondary and Southgate Secondary Schools. Teachers Bill Kennedy, Roger Lucas, and Bud Wilson supervised the student teams. Capt Hugh Watson of the INVADER I and Capt Dave Schuler of OCEAN VIKING assisted in the fishing operations. Ted Carter and Blake Covernton, who were supported by funds from the Province of British Columbia, Ministry of Environment assisted in the tagging operation.
