Canadian Data Report of Fisheries and Aquatic Sciences

These reports provide a medium for filing and archiving data compilations where little or no analysis is included. Such compilations commonly will have been prepared in support of other journal publications or reports. The subject matter of Data Reports reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries management, technology and development, ocean sciences, and aquatic environments relevant to Canada.

Numbers 1-25 in this series were issued as Fisheries and Marine Service Data Records. Numbers 26-160 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Data Reports. The current series name was changed with report number 161.

Data Reports are not intended for general distribution and the contents must not be referred to in other publications without prior written clearance from the issuing establishment. The correct citation appears above the abstract of each report.

Rapport statistique canadien des sciences halieutiques et aquatiques

Ces rapports servent de base à la compilation des données de classement et d'archives pour lesquelles il y a peu ou point d'analyse. Cette compilation aura d'ordinaire été préparée pour appuyer d'autres publications ou rapports. Les sujets des Rapports statistiques reflètent la vaste gamme des intérêts et politiques du Ministère des Pêches et des Océans, notamment gestion des pêches, techniques et développement, sciences océaniques et environnements aquatiques, au Canada.

Les numéros 1 à 25 de cette série ont été publiés à titre de Records statistiques, Service des pêches et de la mer. Les numéros 26-160 ont été publiés à titre de Rapports statistiques du Service des pêches et de la mer, Ministère des Pêches et de l'Environnement. Le nom de la série a été modifié à partir du numéro 161.

Les Rapports statistiques ne sont pas préparés pour une vaste distribution et leur contenu ne doit pas être mentionné dans une publication sans autorisation écrite préalable de l'établissement auteur. Le titre exact paraît au haut du résumé de chaque rapport.

CONTENTS

ABSTRACT

Moores, R. B., and E.G.M. Ash. 1984. Fishway and counting fence operations in Newfoundland and Labrador, 1949-79. Can. Data Rep. Fish. Aquat. Sci. 477: v + 123 p.

The migration of Atlantic salmon adults and smolts and other fishes have been monitored periodically on selected rivers in Newfoundland and Labrador since 1949. Monitoring was conducted at fishways and also at fish counting fence or weir installations. The data obtained at these facilities from 1949 to 1979 are presented. A summary of angling data is also given for each river.

RÉSUMÉ

Moores, R. B., and E.G.M. Ash. 1984. Fishway and counting fence operations in Newfoundland and Labrador, 1949-79. Can. Data Rep. Fish. Aquat. Sci. 477: v + 123 p.

Depuis 1949, la migration de saumons de l'Atlantique adultes et juvéniles ainsi que d'autres espèces de poisson a fait l'objet d'une surveillance périodique dans certaines rivières de Terre-Neuve et du Labrador. Cette surveillance s'est effectuée au niveau d'échelles à poissons ainsi qu'au niveau de barrages de dénombrement de poissons ou d'installations de pêche à fascines. On présente les données recueillies à ces installations de 1949 à 1979. On donne également pour chaque rivière un résumé des statistiques de pêche à la ligne.

INTRODUCTION

Reports have been published annually on the fish enumerated at fishways and fish counting fences in Newfoundland and Labrador, 1949-79 (Anon. 1949-1969b; Peet 1966, 1968, 1971; Riche and Traverse 1970, 1971; Traverse 1972, 1973; Porter and Davis 1974; Pepper et al. 1975; Moores 1978). This report provides details on the migration of Atlantic salmon (Salmo salar) and other fish species through fishways and counting fences operated in Newfoundland and Labrador during 1977, 1978 and 1979. It also includes data summaries on fish migration through facilities operated in Newfoundland and Labrador since 1949 (Fig. 1). Some information on fishway and counting fence design have been provided but details on individual facilities are available in Porter and Davis (1974), and Moores (1978). Data from the recreational salmon fishery have also been included (Button and Wells 1974, 1975; Moores 1976; Moores et al. 1977; Moores et al. 1978, Moores and Tucker 1979; Moores and Tucker 1980).

METHODS

Fishways in Newfoundland and Labrador (Fig. 1) have been constructed for several reasons: to allow Atlantic salmon to reach previously inaccessible sections of rivers; to increase the rate of migration over partial stream obstructions, or, to provide a means of passage around dams. Four types of fishways are currently in use, including the square notch pool and weir, sloped notch pool and weir, vertical slot and submerged orifice (Fig. 2). The type of fishway is dependent on the height of the obstruction, the amount of water available to flow through the facility, and the water discharge characteristics of the river system.

The pool and weir type has been constructed more frequently in the past because it functions particularly well during low water discharge and was relatively cheap to construct. In recent years, the vertical slot type has been found to be more suitable because unlike the other designs, it is not necessary to regulate water flow at high discharge.

At present, there are 24 fishways operating in the province. Since 1949, Atlantic salmon migrations have been monitored periodically at fifteen facilities with six monitored in 1977 and twelve in both 1978 and 1979. Monitoring was generally undertaken by means of a wooden counting trap installed in the fishway. The size of the counting trap was determined by the fishway design but each has a v-shaped entrance. Fish were held in the traps, then counted, sized and released by means of a movable back door. Adults measuring less than 62 cm were considered to be one-sea-winter fish or grilse. Salmon equal to or greater than 62 cm were referred to as multi-sea-winter fish or salmon. Fish were measured against boards 62 cm in length which were placed on the bottom of the counting traps.

Fish counting fences or counting weirs have been designed and installed to monitor the migration of Atlantic salmon adults and juveniles in the freshwater environment. They have generally been of a temporary nature, constructed of

cotton or nylon netting, wire mesh, wood or metal conduit. Problems with fence maintenance, portability and fish mortality associated with the use of netting, wire and wood have led to an almost exclusive use of metal conduit fences. Anderson and MacDonald (1978) have described the construction and installation of this type of fence.

Since 1949, there have been 26 counting fences installed and operated in Newfoundland and Labrador. There were two fences installed in 1977 (one at Western Arm Brook and another on the Exploits River), and in 1978 and 1979, three were installed (one at Western Arm Brook and two on the Exploits River).

Throughout the report, mean water heights have been recorded. It should be noted that these values cannot be used as a measure of discharge. It is merely the height of water in the fishway or counting trap required to maintain optimum water flow for fish movement; water height is controlled by the use of stop logs.

SALMON RIVER River code 0300850

Counting Fence

Salmon River is located on the northeastern side of the Great Northern Peninsula (Fig. 1). It flows east into Ariege Bay, Hare Bay over a distance of approximately 47 km. It drains an area of 252 km^2.

Fence operations on Salmon River were initiated to assess the effect of the West Greenland salmon fishery on Canada's Atlantic salmon stocks (Anon. 1969). Operations began in 1967 and terminated in 1970 (Anon. 1967, 1968; Riche and Traverse 1970, 1971). In 1967, two counting fences were installed, one at km 13 and another on Southwest Brook, a tributary at km 0.5. After 1967 only the former was installed.

The project included several aspects: to monitor Atlantic salmon upstream migration from 1967 to 1970; to enumerate downstream migrations of kelts and smolts in 1968 and 1970; and, to tag smolts, kelts and upstream migrating adult salmon in 1968. With the exception of the 1970 smolt count, all fish counts through the fence were considered to be complete (Table 1). However, only a partial estimate of total river escapement was available as salmon utilized the river below km 13 and some fish moved up Southwest Brook (60 grilse and three large salmon in 1967). The 1970 smolt count was not completed due to a fence washout. The count obtained is estimated to be 25% of the total smolt run.

Annual timing of adult salmon migrations and periods of fence operation are given in Table 2. Catch and effort data from the recreational fishery are presented in Table 3.

INDIAN BROOK River code 0605570

Fishway

Background information on Indian Brook fishway (Fig. 1) is presented in Anon. (1958-1965), Pratt and Sturge (1965), Peet (1966), Anon. (1967-1969), Riche and Traverse (1970, 1971), Traverse (1972, 1973), Porter and Davis (1974), Pepper et al. (1975), and Moores (1978).

Enumeration of Atlantic salmon utilizing the Indian River fishway began in 1958, and with the exception of 1962, has been continued to the present (Table 4). The fishway has been operated without any major problems although for security reasons metal grating was installed over the fishway in 1978-79. A new counting trap was installed in 1979 as a part of regular maintenance of these facilities.

In 1977 and 1978, migration of Atlantic salmon through Indian River fishway was at or near record levels (Table 4). Although restrictions on the use of herring and mackerel nets are thought to have contributed to an increase in river escapement, extremely low water levels in both years made movement upstream via the Indian Falls virtually impossible. Unlike previous years, the majority of salmon are believed to have utilized the fishway.

In 1979, the number of salmon enumerated increased by approximately six times the 1972-76 mean escapement (Table 4). Although fish released by restrictions on the commercial fishery may have again contributed to the increased escapement, it could also be the result of a successful enhancement program. In 1975, juvenile salmon from Indian River spawning channel (reactivated in 1974) were stocked in Black Brook, a tributary of Indian River inaccessible to salmon because of a 10 m falls near its confluence with the main stem (Davis and Farwell 1975). These fish returned as grilse in 1979. Timing of the annual migration in 1979 remained relatively unchanged from previous years (Table 6).

Data obtained at a counting fence (1967-73) operated in conjunction with the Indian River spawning channel are given in Table 7.

Despite river closures due to low water levels and high water temperatures, the recreational salmon fishery on Indian River from 1977 to 1979 was very successful. Angling effort showed some increase over the three year period with catches in 1977 and 1979 among the highest recorded (Table 8). Although low water levels may have made salmon more susceptible to angling, the increase in river escapement undoubtedly contributed to the higher catches.

RIVERHEAD BROOK River code 0605640

Fishways

Riverhead Brook flows northeast into Halls Bay, Notre Dame Bay on insular Newfoundland's northeast coast (Fig. 1). It drains an area of 464 km^2 and flows for a distance of approximately 40 km. The watershed was logged in the late 1940's to the mid 1950's. During the logging period a dam was constructed at km 0.8 and, despite the inclusion of two wooden fishways, it delayed the annual migration of Atlantic salmon. In 1956, counting traps were installed in the fishways to determine the extent of the problem (Anon. 1957). A total of 1264 grilse and 74 large salmon were recorded. With the exception of a few fish which may have moved upstream prior to trap installation, these counts, plus the 468 grilse and four large salmon taken by anglers, are thought to represent the entire 1956 escapement of Atlantic salmon to Riverhead Brook. Examination of the angling data since 1953 suggest little change in river escapement to the system since that time (Table 9).

EXPLOITS RIVER River code 0707790

Fishways

Background information on the enhancement and management of Atlantic salmon the Exploits River (Fig. 1) is available in Mercer (1974), Farwell (1975), Davis and Farwell (1975), Farwell and Porter (1976), Moores (1978). Details of daily operation of fish passage facilities on the Exploits River prior to 1977 are presented in Anon. (1957-65), Peet (1966), Anon. (1967-1969), Riche and Traverse (1970, 1971), Traverse (1972, 1973) Farwell (1972), Porter and Davis (1974), Mercer and Anderson (1974), Pepper et al. (1975).

Bishop's Falls Fishway

Enumeration of Atlantic salmon at Bishop's Falls Fishway has been undertaken intermittently since 1959 (Table 10). The angling catch (Table 11) plus fish counted at Bishop's Falls are believed to represent the entire annual migration to the Exploits River. Weekly counts of salmon are given for the years 1977-79 (Table 12). Migration periods are given in Table 13.

EXPLOITS RIVER (Cont'd) River code 0707790

Bishop's Falls Turbine By-pass Facility

The smolts and kelts enumerated through Bishop's Falls turbine by-pass facility represent only part of the annual downstream migration for the Exploits River (Table 14). Additional migrants are known to move directly over the hydroelectric dam and through the turbines. Weekly migration records for 1977-79 are given in Table 15.

EXPLOITS RIVER (Cont'd) River code 0707790

Great Rattling Brook (Camp I)

With the exception of 1973-74, enumeration of Atlantic salmon has been undertaken at Great Rattling Brook (Camp I) since 1960 (Table 16). Migrants recorded at Camp I have previously been released from the Bishop's Falls fishway and angling data from this tributary (Table 17) are included in total angling data for the Exploits River (Table 11). Weekly counts of Atlantic salmon for the years 1977-79 are given in Table 18. Migration periods are given in Table 19.

Table 16. Escapement of Atlantic salmon and other fishes* through the Great Rattling Brook fishway, 1960-79, including fish transferred to Noel Paul's Brook, 1975-79.

EXPLOITS RIVER (Cont'd) River code 0707790

Grand Falls Fishway

The Grand Falls fishway was constructed in 1972-73 and has had only limited success in collecting fish for the spawning channel at Noel Paul's Brook (Table 20). High water discharge in the fishway have contributed to the problem but pollution from the nearby paper mill is believed to inhibit salmon from moving up into the fishway. Weekly counts of salmon obtained at the site for 1977-79 are given in Table 21 and periods of migration in Table 22.

Table 20. Escapement of Atlantic salmon and other fishes through the Grand Falls fishway, 1974-79.

Year	Atlantic Salmon		Total	% Grilse	Brook Trout		Smelt	Ouananiche

EXPLOITS RIVER (Cont'd) River code 0707790

Counting fences

Since 1969 counting fences have been installed and operated intermittently on a number of small tributaries draining into the Exploits River. Fences have been constructed of both netting and metal conduit and designed to monitor the migration of both indigenous fish populations and progeny of adults from the Noel Paul's spawning channel. Table 23 summarizes data obtained at these fences.

Table 23. Fish counts from temporary counting fences operated on tributaries of the Exploits River, 1969-79.

RATTLING BROOK River code 0707810

Counting fence

Rattling Brook is located on the northeast coast of insular Newfoundland (Fig. 1). Prior to 1957, it drained approximately 160 km^2 and it was 30 km long. However, in 1957, the river was blocked by a hydroelectric dam and at present, except for a short section below the power house, it is mostly dry riverbed.

Before the impoundment, Rattling Brook was estimated to have an annual river escapement of 700-900 Atlantic salmon. Because construction of a fishway or spawning channel at the hydroelectric site was felt to be too costly, the Rattling Brook salmon were captured by means of a counting fence and transferred to Great Rattling Brook, a tributary of the Exploits River.

The details and success of the transfer and subsequent establishment of a viable salmon run to Great Rattling Brook has been document by Sturge (1966), Pratt et al. (1973) and Farwell and Porter (1976). This report presents the data obtained at the counting fence between 1956 and 1965 (Table 24).

Table 24. Numbers of Atlantic salmon recorded at the Rattling Brook counting fence and transferred to Great Rattling Brook, 1956-65.

+Of the 406 escapement, 336 were transferred to Great Rattling Brook and 70 were transferred to Bishop's Falls.

DOG BAY RIVER River code 0708480

Counting Fence

Dog Bay River flows northeast into Hamilton Sound, Notre Dame Bay. It drains an area of 364.4 km^2 and has a main stem length of 50.9 km. In 1972 a counting fence was installed on the system to determine its suitability as a donor stream of Atlantic salmon brood stock. If the system was found to have surplus stock, adult salmon were to be transferred for an enhancement program on the Exploits River.

The counting fence was positioned approximately 4.8 km from the river mouth and operated from 30 June to 14 October. During the period, 391 grilse and 207 large salmon were recorded. The first adult was enumerated on the 30 June and the last on 8 October, with peak migration occurring between 16-22 July. Because of the delay in fence installation and the distance between the fence and the river mouth, the 1972 salmon count is not considered to represent the entire annual migration to Dog Bay River (Traverse 1973). The number of large salmon recorded also suggest some problem with the sizing of migrants, the number is not consistent with the angling data (Table 25).

GANDER RIVER River code 0908610

Counting Fences

Details on the design and operation of two counting fences on the Gander River (Fig. 1) are available in Anon. (1951) and Mercer and Anderson (1974).

A counting fence was installed on the lower Gander River in 1951 as part of a preliminary investigation on the life history of Atlantic salmon in Newfoundland and Labrador. It was operated from 7 June to 30 September but a washout occurred in August and a proportion of the salmon migration was missed. A total of 9700 salmon were enumerated of which 79.6% were judged to be grilse. The total estimated river escapment, based on migration rate, was 12,000 fish (Anon. 1951).

In 1973, a counting fence was installed on the Northwest Gander, a major tributary of the Gander River flowing into Gander Lake. Installation of the fence was in conjunction with a salmon enhancement program on the Exploits River. If sufficient numbers of salmon entered the tributary, surplus spawners were to be removed and transported to the Noel Paul's Spawning Channel. The fence was operated from 5 June to 18 August during which time 603 grilse and 25 large salmon were enumerated. The count was not complete due to several fence washouts. The estimated annual run based on migration rate through the fence and anglers catch (Table 26) was in the range of 1000-1500 fish (Mercer and Anderson 1974). This number was judged insufficient to permit removal of adults for the enhancement program.

SALMON BROOK (GANDER RIVER) River code 0908610

Fishway

Details on design of the Salmon Brook fishway (Fig. 1) and background information on fishway operations prior to 1977 are given in Anon. (1958-62), and Traverse (1972, 1973). A record of fish enumerated at Salmon Brook from 1957 to 1979 is given in Table 27.

In 1977, there was insufficient funds to enumerate Atlantic salmon utilizing Salmon Brook fishway. In 1978, enumeration was resumed and 807 adult salmon were recorded. The migration comprised of 755 grilse and 52 large salmon (Table 28). Low water levels were a problem in 1978, and at times during the season, prevented salmon from reaching the fishway. This may have delayed the migration and additional migrants may have used the fishway after enumeration was terminated in September.

Poaching was another serious problem at Salmon Brook fishway during 1978. Numerous attempts were made to remove salmon from the fishway and acts of vandalism were common. The numbers of salmon taken during these incidents are unknown.

In 1979, the Salmon Association of Eastern Newfoundland (S.A.E.N.) were awarded a contract to operate a number of fishways in insular Newfoundland. Salmon Brook fishway was among these facilities and enumeration of adult salmon was undertaken by their staff from 28 June to 21 September. The problem of low water levels was even more acute in 1979 than the previous year, and with the exception of two fish that moved through the fishway in late July, no fish could enter Salmon Brook from the Gander River until mid-August. A total of 410 salmon were eventually enumerated but the high count in September suggests that it is only a partial count (Table 28). It was also suspected that a large number of fish moved directly upstream via the falls. Examination of migration periods during previous years indicate that the timing fluctuates widely (Table 29) and may be influenced by water discharge.

Poaching and vandalism at the facility in 1979 were only minor problems, alleviated in part by the installation of metal grating over the fishway.

The recreational fishery on Salmon Brook was closed for a portion of the angling season in both 1978 and 1979 due to the low water levels (Table 30).

MIDDLE BROOK River code 1109760

Fishway

A brief history and design of the Middle Brook fishway are given by Porter and Davis (1974) and Moores (1978). Details of fishway operations prior to 1977 are available in Anon. (1956, 1957b-1960), Traverse (1973), Porter and Davis (1974), Pepper et al. (1975).

The migration of Atlantic salmon at the Middle Brook fishway was not monitored in 1977. The facility was however operational. Enumeration of migrants was resumed in 1978. A total of 1428 Atlantic salmon were recorded of which 16 were large salmon (Table 31). Peak migration occurred during the week ending 22 July (Table 32). There were no major operational problems experienced at the fishway in 1978 although low water levels may have delayed fish migration. Poaching on Middle Brook was a serious problem and a large number of salmon were probably removed from the river. Poachers also broke into the fishway on two occasions and removed an unknown number of fish.

The recreational fishery took 391 grilse and one large salmon from Middle Brook in 1978. Effort totalled 1322 rod days with a catch per unit effort (CUE) of 0.30 (Table 33).

Operation of the Middle Brook fishway in 1979 was undertaken by S.A.E.N. This organization operated the facility from 25 June to 12 September. A total of 1404 Atlantic salmon were enumerated of which 54 were large salmon. Twenty-one adults were enumerated on the first day of operation which suggest that a number of fish moved upstream before enumeration began (Table 31). Peak migration occurred from 15 July to 21 July (Table 32).

Poachers again caused problems at the fishway in 1979. They broke into the counting trap on at least three occasions and removed an unknown number of fish. Poaching in the river was reported to be a major problem; a situation that was compounded by extremely low water levels and high water temperatures. Installation of metal grating over the fishway in 1979 reduced poaching and vandalism problems at the fishway.

The recreational fishery at Middle Brook was closed for all but four weeks in 1979 due to low water levels and high water temperatures. Anglers did however manage to take 28 grilse during the short season (Table 33).

Despite poaching, and probably as a result of a fine effort by the counting trap attendants in operating the fishway coupled with new fisheries regulations that reduced salmon by-catch in herring and mackerel nets in the area, record numbers of Atlantic salmon passed through the Middle Brook fishway in both 1978 and 1979 (Table 34).

NOTE: Angling occurred above and below fishway.

TERRA NOVA RIVER River code 1110220

Fishways

Background information on the two Terra Nova River fishways (Fig. 1) is given in Anon. (1956, 1957b-1965), Peet (1966), Anon. (1967-69), Riche and Traverse (1970, 1971), Traverse (1972, 1973), Pratt et al. (1973), Porter and Davis (1974), Pepper et al. (1975), and Moores (1978).

In 1977, salmon migration was monitored only at the upper fishway. The operation period for this facility was from 2 July to 27 August. A total of 633 adult salmon were counted of which 262 were recorded as large salmon (Table 35). There is however some doubt as to the validity of the large salmon count as it was disproportionally greater than the recreational fishery. Peak migration occurred during the week ending 23 July (Table 36). There were no major problems at the fishway in 1977 and fish numbers appear comparable with previous years (Table 37).

In 1978 salmon were enumerated at both the upper and lower fishways. It was the first time in five years that salmon were enumerated at the lower fishway and, although poachers are known to have taken some adults, no major problems were encountered. Extremely low water levels in 1978 led to closure of the recreational fishery but an overflow dam located near the fishway directed sufficient water to permit continuous operation of the facility. The total count of adult salmon was 830 of which only 20 were large salmon (Table 38).

At the upper fishway 436 grilse and 88 large salmon were counted in 1978 (Table 35). Again the validity of the large salmon count is questionable considering that only 20 large salmon were enumerated at the lower facility. Operations in 1978 were conducted without poaching problems and the only fish mortality occurred when two fish were crushed under the trap. Peak migration was from 23 July to 29 July. This was comparable to previous years (Table 36).

In 1979 fish migration was again monitored at both fishways. Operations were under contract to S.A.E.N. and with the exception of four mortalities, and a reluctance of some migrants to enter the counting trap at the lower facility, no major problems were encountered.

The total 1979 count at the lower fishway was 739 salmon of which 170 were large salmon (Table 38). Peak migration was recorded during the week of 21 July (Table 39). Enumeration at the upper fishway showed 485 salmon of which 30 were large salmon (Table 35). A peak in migration was not apparent for 1979 and the 13 fish counted during the last week of fishway operation indicated that the migration had not been completed when enumeration was stopped on 3 September.

Examination of 1977-79 fishway counts in Terra Nova River suggest little change in stock size in Terra Nova River. The mean 1978-79 count for the lower fishway was 784 fish (Table 40). This was only 8% below the mean 1971-73 count and, considering that migrants can move directly over the falls, it was not

thought to represent any major change in migration size. The mean 1977-79 count for the upper fishway was 548 salmon. This is comparable to the 1970-74 mean of 509 but does suggest an upward trend (Table 37).

Angling data for this river shows an increase in success rate for the period 1977-79 over previous years which had low water levels. Increased emphasis on data collection may partly account for the increase of recorded numbers of fish angled (Table 41).

TERRA NOVA RIVER (Cont'd) River code 1110220

Counting Fence

Background information on fence design and operation are given by Anon. (1952).

A counting fence was installed on the Terra Nova River in 1952 as part of the preliminary investigation of the life history of Atlantic salmon in Newfoundland and Labrador. It was located a short distance above the river mouth and operated from 9 June to 29 September. During this period, 425 grilse and 26 large salmon were enumerated. Despite a brief washout this count was thought to represent the complete 1952 salmon migration to the river. The first fish was recorded on 14 June, the peak migration occurred during the week ending 26 July, and the last fish was released on 21 September. Anglers took 58 fish of the total released from the fence.

Monitoring of the smolt migration out of Terra Nova River was also attempted in 1952 but problems with holding the fyke nets and seines in position resulted in only 95 smolt being enumerated.

NORTHWEST RIVER (Port Blandford) River code 1210880

Fishway

Details on fishway construction and operation are given by Anon. (1949).

In 1948, a fishway was blasted at a falls on Northwest River approximately 3.2 km from the mouth. During constructon 48 salmon were observed utilizing the fishway. In 1949, a counting trap was installed on the fishway and 62 adult salmon enumerated. A river blockage by pulp logs is believed to have prevented additional migrants from reaching the fishway.

No count of salmon utilizing the facility has been obtained since 1949 but angling data has been collected since 1958 (Table 42).

NORTHEAST RIVER (PLACENTIA) River code 2903070

Fishway

Background information on the Northeast River fishway (Fig. 1) is presented by Traverse (1973), Porter and Davis (1974), Pepper et al. (1975), and Moores (1978).

In 1977, the Northeast River fishway was operable but the Atlantic salmon migration was not monitored.

Monitoring of the Atlantic salmon migration was resumed again in 1978. From 23 June to 11 September a total of 422 salmon were recorded. Thirty-two of these were large salmon (Table 43). Peak migration was from 15 July to 22 July (Table 44). Low water levels in 1978 delayed salmon migration in the river but there was sufficient water to operate the fishway. Poaching was a serious problem on Northeast River during the season. At least four attempts were made to remove salmon from the counting trap and at least one successful attempt was made to net the pool immediately below the facility. The numbers of salmon removed are unknown.

Despite unfavourable water conditions, the recreational fishery was fairly successful. The catch of 161 grilse has been exceeded only once since 1973 and the CUE of 0.13 was above the 1972-76 mean CUE of 0.12 (Table 45).

Fishway operation and monitoring of the Atlantic salmon migration in 1979 was conducted by SAEN. A total of 491 salmon were recorded of which 37 were large salmon (Table 43). The 1979 migration was a record one (Table 46) despite the extremely low water levels experienced again in 1979. Peak migration was recorded during the week ending 14 July (Table 44). There were no major problems experienced with fishway operation in 1979.

The recreational fishery on Northeast River was closed for a two week period because of low water levels. An angling effort of 969 rod days did however yield 138 grilse with a CUE of 0.14. This was comparable to the CUE since 1972 and suggests that a higher catch would have occurred without the river closure (Table 45).

NORTHEAST RIVER (PLACENTIA) River code 2903070

Counting fence

Fyke nets

In 1971, a counting fence was installed at km 0.8, to enumerate the river escapement of Atlantic salmon. The project was initiated to assess the potential of Northeast River to provide Atlantic salmon brood stock for future salmon enhancement projects on the Avalon Peninsula (Traverse 1972). The fence was operated from 17 June to 27 September, during which 159 grilse and 21 large salmon were counted. A partial washout prevented a complete count. Total river escapement was estimated to be 239 fish including: seven fish observed before fence installation, 20 fish thought to have moved upstream during the washout and 32 fish angled below the fence site.

In 1977, as part of a study of male precocity in Atlantic salmon, fyke nets were installed at the outlet of Fitzgerald's Pond, approximately 9.6 km from the mouth. The nets were fished from 2 May to 10 June, during which time 10,621 Atlantic salmon smolts were recorded. Problems with water discharge and debris prevented a complete count (Dalley 1979). In addition, 446 salmon parr, 95 brook trout and 90 eels were enumerated.

COME BY CHANCE RIVER River code 3003740

Counting Fence

Come by Chance River is located on the isthmus of the Avalon Peninsula (Fig. 1). It drains an area of 64.0 km^2 and has a main stem length of 17.2 km.

In 1970, a proposal was made to utilize the Come By Chance River system as a water supply for an industrial complex in the community of Come By Chance. A study was initiated in 1971 to assess the size of the fish population in the system. In 1971-72 a temporary metal counting fence was installed at the river mouth and both upstream and downstream migrants were monitored (Traverse 1972, 1973).

In 1971, the period of operation was from 5 May to 13 September. A total of 3552 Atlantic salmon smolts were enumerated moving downstream and 22 adult salmon comprised the upstream migration. Most of the latter were grilse (Table 47). Peak migration for the smolts was 9-15 May and for the adults from 27 June to 3 July (Table 48). Washouts due to high water permitted only a partial count of adult migration. The large number of smolts enumerated on the first day of fence operation also suggests that some smolts may have moved out to sea before fence installation.

In 1972, the counting fence was maintained from 10 May to 20 October. There were 8374 smolts and nine salmon recorded during this period (Table 47) but only the smolt count was considered to be complete (Traverse 1972). Problems with fence installation and high water levels allowed some adults to bypass the fence.

In 1971 and 1972, only nine and eight grilse respectively were angled on the Come By Chance River, in spite of 192 and 528 rod days of effort respectively. Data from previous years indicate that anglers had been more successful in other years (Table 49).

Plans for additional monitoring were discontinued when the closedown of the Come By Chance oil refinery made the requirements for additional water supply unnecessary.

LONG HARBOUR RIVER River code 3409780

Counting Fence

Fyke Nets

Long Harbour River is located on the south coast of insular Newfoundland (Fig. 1). It flows southeast into the bottom of Fortune Bay over a distance of 418 km. The drainage area is 932.4 km^2.

In the early 1960's Long Harbour River was identified as a potential site for hydroelectric development. Because there was limited knowledge on the fish populations in this system, a project was undertaken by Resource Development Branch in 1966 to gather additional information. The project included the use of fyke nets and a counting fence to enumerate both salmon smolts and adults and smolts were fin clipped for estimation of population size. The fyke traps were installed from 10 May to 18 August and captured 5494 smolts. The mark recapture data estimated total smolt migration to be 114,111 smolts (Riche 1969). Analysis of weight, length and age frequency showed smolts to have a mean weight of 36.5 gm, mean length of 17.5 cm and 84% to be age 3+. Other fish species taken in fyke nets are shown in Table 50.

One adult trap was installed on 22 June and operated until the 18 August. A total of 876 adult salmon were enumerated of which 99% were grilse (Table 50). The adult count was not considered to be complete because of two washouts resulting from high water discharge (Riche 1969). From a sample of 120 adults taken in the recreational fishery, sex ratio of adults was determined to be 75% females.

The recreational fishery in 1966 took 274 grilse and one salmon with an effort of 84 rod days. The CUE was a 3.27 (Table 51).

BAY DU NORD RIVER River code 3410790

Fishway, Counting Fence, Fyke Nets

The Bay du Nord River is located on the south coast of insular Newfoundland (Fig. 1). It flows south into the west side of Fortune Bay and drains an area of 117 km^2.

In 1949, a fishway was blasted at Smokey Falls approximately 14 km from the river mouth. Fishway construction was part of a river improvement program designed to increase salmon production in waters limited by natural barriers to fish migration. The fishway was completed in June 1949, but no Atlantic salmon utilized the facility during that year. In 1950, despite an apparent abundance of salmon in the river, only 12 grilse were recorded at the fishway (Anon. 1949, 1950). Monitoring at the fishway was discontinued after 1950.

In 1952, as part of preliminary investigation of the biology of Atlantic salmon in Newfoundland, fyke nets and a counting fence were installed on the Bay du Nord River. The fyke nets were unsuccessful in capturing a significant number of smolts and were not used after 1953. The counting fence was operated for three years, 1953-55, to monitor both smolt and adult salmon migrations. Data obtained at the fence are presented in Table 52. In addition to enumerating fish migration, an extensive tagging program was conducted at the site, the details of which are available in (Anon. 1953, 1954, 1955). Timing of migrations and angling data for Bay du Nord River are given in Tables 53 and 54.

SALMON RIVER River code 3614070

Fishway

Salmon River is located on the south coast of insular Newfoundland (Fig. 1). Prior to 1965 it was one of the largest rivers on the island with a drainage area of approximately 2708 km^2 and a main and tributary length totalling 480 km. Since 1965 the system has become a part of the Bay D'Espoir Hydroelectric Power Development and more recently part of the Upper Salmon Hydroelectric Development.

Access for Atlantic salmon to Salmon River was extremely limited even before 1965. The river had a complete obstruction to Atlantic salmon migration at km 2.2 and another at km 5.6. It was thought that at certain water levels access may have been possible at the former. In 1949, in an effort to increase the area available for Atlantic salmon, a fishway was constructed at the lower falls by the Fisheries Research Board of Canada. Following construction in 1949, a counting trap was installed and operated for the month of September. A total of 15 salmon were recorded of which six were large salmon (Anon. 1949).

In 1950, the counting trap was again installed and operated from 25 June to 10 September. A count of 20 grilse and 10 large salmon was obtained which was thought to represent the entire run above the falls. Peak migration was in the week ending 29 July (Anon. 1950).

The counting trap was not reinstalled again until 1960. At that time, the trap was operated from 19 June to 10 September with a total of 26 grilse and 1 large salmon enumerated. An anticapted increase in population as a result of the presence of the fishway did not materialize. Ineffective operation of the fishway was thought to have been the main problem, there was only a small amount of rearing area between the fishway and the next complete obstruction. Peak migration in 1960 occurred during the week ending 30 July (Anon. 1960).

Angling data from Salmon River was collected only intermittently up to 1974. Since 1974, angling effort has averaged only 30 rod days, with the catch ranging between 0 and 21 grilse per season (Table 55).

WHITE BEAR RIVER River code 3717440

Counting Fence

White Bear River flows south into White Bear Bay on Newfoundland's south coast (Fig. 1). The river was at one time approximately 54.7 km long with a drainage area of 2046 km^2 but in 1969 approximately 60% of the drainage area was diverted to form part of the water storage for the Bay D'Espoir Power Development.

The system consisted of 21 major tributaries, only one of which was accessible to Atlantic salmon prior to 1972. At that time remedial work between km 19 and km 21.7 on the main stem opened up an additional four tributaries to salmon migration.

In 1973, a counting fence was installed at km 32 to determine the extent of salmon migration above the obstructions. The fence was operated from 20 July to 27 September with a washout occurring from 20 July to 6 August. No salmon were recorded at the site but this was not considered to be conclusive evidence that salmon could not reach the area. Some fish may have moved above the fence during the washout or others may have spawned immediately below the counting fence (Porter and Davis 1974).

Angling data from the White Bear River for 1953-79 are given in Table 56.

LITTLE CODROY RIVER River code 4000140

Counting Fence

Background information on fence design is available in Murray (1968), analysis of data on the biology of Atlantic salmon on Little Codroy River has been completed by Murray (1968). This report presents data summaries of salmon migrations at the fence (Table 57) and angling data for the years 1953-79 (Table 58). The history and purpose of the Little Codroy River facility has been summarized by Blair and Murray in the Report of the Newfoundland Fisheries Research Station for 1953, and is as follows:

> "Decline of the Atlantic salmon fishery in eastern Canada has provided stimulus for expansion of research in an attempt to improve management practices. To provide data for proper adjustment of the fishery regulations, a long term research project is being set up on the Little Codroy River in Newfoundland and will begin operation during the spring of 1954.
>
> The purpose of the project is to provide information on the effects of the physical, chemical and biological factors of the freshwater environment of the salmon in an attempt to assess the causes of natural fluctuations in their abundance."

The adults, kelts and smolts were enumerated from 1954 to 1963.

HARRYS RIVER River code 4101200

Counting Fence

Harry's River is located on the west coast of Newfoundland near the town of Stephenville (Fig. 1). It flows for a distance of 35 km and drains approximately 815 km^2 before flowing into St. George's Bay.

In 1966, a proposed industrial development for Stephenville included diversion and utilization of water from Harry's River for domestic and industrial purposes. As part of a preliminary assessment of the environmental impact, enumeration of the Atlantic salmon population was conducted during the summer of 1967. A counting fence was installed at km 4.4 and operated from 22 June to 2 September. Unfortunately, high water discharge washed out the structure on two occasions and a complete count could not be obtained (Anon. 1968; Downer 1968).

During the operation period a total of 1245 salmon were recorded, of which 266 were considered to be large salmon. Peak migration occurred during the week of 15 July. Angling data for the same period shows an effort of 2630 rod days, 954 fish being angled. Some 248 of these were large salmon (Table 59).

Fortunately, an alternate water supply was found for the industrial development, and Harrys River remains unaltered.

HUMBER RIVER River code 4402430

Counting Fence

The Humber River is located on the west coast of insular Newfoundland and flows southwest into the Bay of Islands. The Humber River is the second largest river on the island (Exploits River is the largest) and drains an area of 7540 km^2. The system is accessible to Atlantic salmon to km 99 were Main Falls, a 15 metre high obstruction, blocks further migration. Because the area above Main Falls represents approximately one third of the drainage area, a fishway has been considered for the site. As part of a preliminary survey for fishway construction, a counting fence was installed in 1967 approximately 16 km below Main Falls. The intent was to determine the size of Atlantic salmon migration to the falls and in turn assess the potential for natural stocking through straying should a fishway be constructed.

The counting fence was operated from 8 July to 16 September with a total of 144 grilse and 16 large salmon recorded. Peak migration occurred between 20 August and 2 September but may have been delayed by low water levels (Anon. 1968).

Despite several engineering surveys and biological assessments since 1967 (Anderson 1974, unpublished data) a fishway has yet to be constructed at Main Falls.

In 1966, as part of an enhancement program on the Exploits River (Mercer 1974; Porter et al. 1974; Farwell 1975; Farwell and Porter 1976; Moores 1978), the Humber River was assessed for its potential as a donor stream for salmon. It was determined that between 501 to 700 adult salmon could be removed per year without any detrimental effects to the existing population. Adies Stream, a major tributary of the Humber River (Fig. 1), was chosen as the collection site and, in 1967, a counting fence was installed. The counting fence was operated for six years primarily as a means of collecting fish for the transfer to the Exploits River (Anon. 1968-69, Riche and Traverse 1970, 1971; Traverse 1972, 1973). Records of fish numbers moving through the fence were also kept after 1968 but none of the counts represented the entire salmon run to Adies Stream (Table 58). The numbers of salmon transferred to the Exploits River are also given in Table 60. Angling data for the Humber River are shown in Table 61.

Table 60. Numbers of Atlantic salmon enumerated at Adies Stream, Humber River and numbers transferred to the Exploits River. Numbers in parenthesis indicate transfer mortalities.

LOMOND RIVER River code 4503920

Fishway

Background information on fishway design and operations on Lomond River (Fig. 1) prior to 1977 are presented in Anon. (1949), Anon. (1962-1965), Peet (1966), Anon. (1967-1969), Riche and Traverse (1970, 1971) Traverse (1972, 1973) Porter and Davis (1974), Pepper et al. (1975), and Moores (1978).

In 1977, the Lomond River fishway was operated from 26 June to 17 September. A total of 203 Atlantic salmon were enumerated of which 11 were large salmon (Table 62). The first migrant was recorded on 1 July and the last fish was counted when the facility was closed on 17 September. Peak migration was during a two week period 10-23 July (Table 63). There were no problems experienced at the fishway in 1977 although some minor leaks have developed in the lower pools. The attendant also reported some fish were reluctant to enter the fishway and indicated that a few may have successsfully surmounted the falls.

Operation in 1978 was from 25 June to 28 September. There were 129 Atlantic salmon recorded of which 12 were large salmon (Table 62). The first fish was enumerated on 27 June and the last on 28 August. Peak migration was from 22-29 July (Table 63). There were no major operational difficulties in 1978 although low water discharge during September did reduce the efficiency of the facility. A diversion dam is required at the exit to permanently solve this discharge problem. It was again noted in 1978 that salmon were reluctant to enter the fishway and particularly the counting trap.

Fishway operations in 1979 were contracted to SAEN. They operated the facility from 19 June to 07 September and recorded a total migration of 195 grilse and one large salmon (Table 62). The first migrant was recorded on 11 July and the last on 28 August. Peak migration was from 21-28 July (Table 63). Again in 1979 there were no major problems at the facility. Plans for installation of a diversion dam and new counting trap had to be postponed until 1980. Metal grating was installed over the the fishway in 1979 to prevent any future poaching problems.

Migration of Atlantic salmon through the Lomond River fishway has shown considerable improvement over the last four years (Table 64). Although some increase in escapement of Atlantic salmon to Lomond River may have occurred, the increase through the fishway is mainly attributible to careful attention given to fishway operation by the counting trap attendants.

The recreational fishery on Lomond River in 1977, 1978 and 1979 took 529, 374 and 237 Atlantic salmon, respectively. These catches are comparable to previous years despite the extremely poor fishing conditions caused by low water levels (Table 65).

TORRENT RIVER River code 4704800

Fishway

Background information on the Torrent River fishway (Fig. 1) prior to 1977 is available in Anon. (1967-1969), Riche and Traverse (1970, 1971), Traverse (1972, 1973), Porter and Davis (1974), Pepper et al. (1975), and Moores (1978). Details of fishway design are given by Porter and Davis (1974).

Torrent River was the site of an Atlantic salmon enhancement program from 1972 to 1976. Over the five year period adult salmon from Western Arm Brook were transferred to the Torrent River system in order to augment a limited natural run through the fishway (Table 66). The intent was to populate the stream area above the fishway at a faster rate than was occurring through straying from the indigneous salmon population below the fishway. The success or otherwise of this program was to be determined by the size of the migration at the fishway from 1977 to the present (Table 66).

The 1977 migration suggested that the transfer of brood stock has been successful. The 822 adults (789 grilse and 33 large salmon) recorded in 1977 were a considerable increase over previous years. The 1978 count was 23% greater than 1977; it included 968 grilse and 21 large salmon (Table 67). In 1979, the salmon migration was more than double the two previous years. This was higher than anticipated and can only be partially related to the enhancement program. It is possible that introduction of new regulations restricting the use of herring and mackerel nets may also have accounted for the increased river escapement. The 1979 migration was comprised of 1984 grilse and 39 large salmon (Table 67).

During the years 1977-79 there were no major problems with the operation of the Torrent River fishway. Full time attendants have been employed at the facility (under contract to SAEN in 1979) and, with the exception of a new counting trap installed in 1978, no major repairs have been necessary.

Timing of the annual migraton did not differ greatly over the three years although peak migration had occurred as late as August prior to 1977 (Table 68).

In an effort to ensure that sufficient adults migrated above the fishway to adequately stock the area, the sport fishery was closed in 1977 and opened in 1978-79 only after sufficient number of spawners had moved upstream (Table 69).

From 1973 to 1976, a counting fence was installed on Main Parts Brook, a tributary of Torrent River to monitor downstream migration of any transferred salmon and upstream migration of salmon which migrated through the fishway into this tributary. From 1972 to 1975, it was located 1.6 km upstream; in 1976 it was relocated to the mouth of the tributary and adapted to enumerate smolts and kelts as well as upstream migrating adults (Moores 1978). The data collected at the site are presented in Table 70.

EAST RIVER River code 4704840

Counting Fence

East River, or Big East River as it is known locally is located on the Great Northern Peninsula on Newfoundland's west coast (Fig. 1). It flows into Hawkes Bay just north of the Torrent River. In 1971, a counting fence was installed on East River to assess whether or not there was sufficient Atlantic salmon to be used as brood stock on Torrent River (see Torrent River, p. 95).

The counting fence was installed on 27 June and operated until 3 August. Unfortunately, fluctuations in water discharge in the system were such that the fence was washed out on 28 June and again on 3 August. Despite an indication from angling data (Table 71) of sufficient salmon to permit a transfer to Torrent River, the fence was not reinstalled after 3 August due to the unfavourable conditions. A partial count of 68 grilse and 19 large salmon was obtained during the brief operating period (Traverse 1972).

WESTERN ARM BROOK River code 4905190

Counting Fence

In 1971, as part of the Torrent River Atlantic salmon enhancement program (see p. 95), a temporary counting fence was installed on Western Arm Brook. Its main function from 1971 to 1976 was the collecton of adult salmon for transfer to Torrent River (Traverse 1973; Riche 1973; Traverse 1973, Porter and Davis 1974; Pepper et al. 1975; Moores 1978). Subsequent to 1977, the fence was operated primarily to collect additional data on the Atlantic salmon population (Chadwick et al. 1978; Chadwick 1981).

In 1977, the fence was operated from 29 May to 23 October. The smolt count during this period was 9640 with 298 kelts also recorded moving downstream (Table 72). The first smolt was recorded on 3 June, the migration peaked between 11 June and 18 June and the last smolt was recorded on 5 July. Other fishes recorded during the operating period included 358 Atlantic salmon parr, 373 brook trout, 65 American eels, 354 American smelt, 12 American shad, and 26 three-spined sticklebacks.

The 1977 adult upstream migration began on 25 June, peaked during the week of 10-16 July and terminated on the 23 September (Table 73). During the period a total of 362 grilse and three large salmon were recorded (Table 74). There were no major problems with fence operations in 1977 but in the early part of the season, there was some mortality at the counting fence of adults which had been tagged in St. Barbe Bay.

In 1978, the fence was in operation from 27 May to 30 October. During that period a record migration of 13071 smolts were recorded (Table 72). The first smolt was recorded on 28 May, the migration peaked from 13-19 June and the last smolt during the spring migration was on July 14 (Table 73). A smolt trap which was installed in September recorded 28 juvenile salmon, of the size and appearance of smolts, migrating downstream.

Kelts moving downstream in the spring migration totalled 210 (Table 72). Other fishes enumerated included 899 Atlantic salmon parr, 1000 brook trout, 69 American eels, 527 American smelt, 22 three-spined sticklebacks, and two American shad.

In 1978, only 293 grilse and one large salmon were recorded at Western Arm Brook (Table 74). This was the lowest count on record and it was thought to be the result of a poor sea survival of smolt due to adverse environmental conditions. The first fish was released on 30 June and the last on 17 September. Peak migration occurred during the period 15-22 July (Table 73). There were no mortalities among adults at the fence in 1978.

In 1979, the smolt count was not complete but the total number of migrants was estimated to be 9400. The smolt migration was in progress at the time of fence installation and 520 smolts were enumerated on the first day of fence operation. The actual count of 8340 smolts was adjusted using a comparison to migrations in previous years (Chadwick 1981). Peak smolt migration in 1979 was

on 27 May and the last smolt was observed on 03 July. In addition, 235 Atlantic salmon parr, one American eel, 53 American smelt and 21 three-spined sticklebacks were recorded at the fence. All kelt were believed to have moved out of the river before fence installation.

The adult migration in 1979 totalled 1578 fish. This was the highest number ever observed at the fence. All migrants were grilse (Table 74). The last fish was counted on 14 September (Table 73). No mortalities occurred at the fence in 1979.

The sport fishery on Western Arm Brook has been partly restricted since the system has been utilized in the enhancement program on Torrent River. Angled catch declined to only 11 and 23 fish in 1977 and 1978. In 1979, the sport fishery was open only for a few days because of low water levels (Table 75).

ST. CHARLES RIVER River code 5101420

Counting Fence

St. Charles River is located in southern Labrador on the southern side of St. Lewis Sound (Fig. 1). It has a drainage area of 311 km^2 with a main stem length of 45 km.

A counting fence of wood and netting was installed on the river in 1966 as part of a program to gather data on fish species and abundance in southern Labrador rivers. The fence was located approximately 91 m from the river mouth and operated from 29 June to 24 July. Both downstream and upstream migrants were enumerated, although neither count was considered to be complete (Peet 1971). Total downstream migrations consisted of 30 smolts, 15 parr, two brook trout, two Arctic charr, and one alewife. Upstream migration comprised 993 fish of which 877 were Arctic charr, 86 brook trout, and 30 Atlantic salmon. Five of the salmon were large. In addition to fish counts, data on age, weight and length of charr and salmon were taken, the details of which are available in Peet (1971). There were no angling data recorded for St. Charles River although some angling by local residents is known to occur.

SAND HILL RIVER River code 5205820

Counting Fence

Sand Hill River is located in Labrador just south of Hamilton Inlet. It flows east into Table Bay near the community of Cartwright (Fig. 1). The river drains approximately 1625 km^2 and has a main stem length of 79 km.

In 1967, two counting fences were installed on the system, one on the main stem and another on a major tributary, Northwest Brook. Fence operations were in connection with the Greenland Salmon Fishery Investigation and intended to assess the Atlantic salmon population for its potential in a smolt tagging program. Unfortunately, high water discharge displaced the main fence in July and only a partial count of Atlantic salmon was obtained. During the brief operating period 554 grilse and 87 large salmon were enumerated at the main fence (Table 76). Operations at the Northwest Brook also had problems with high water and some salmon may have bypassed the counting trap. A count of 122 grilse and 16 large salmon was eventually obtained (Table 77). In addition to Atlantic salmon five additional fish species were observed at the counting fences (Table 76).

In 1968, the Sand Hill River was chosen as the site for Greenland Salmon Fishery Investigation and installation of a permanent counting fence was started on the main stem. The fence was completed in 1969 but its construction plus high water level permitted only a partial count of migrants in that year. In 1970 through to 1973 enumeration of both upstream migrants and downstream moving salmon smolts was successfully undertaken (Table 76). Smolt tagging was also conducted at the site. Migration periods are given in Table 78 and 79.

After 1973, operation of the Sand Hill River counting fence was terminated due to lack of funding and in 1978 the permanent living quarters were leased as a commercial sport fishery camp.

During the seven years of operation, extensive biological data on salmon and other fish species were collected at the site and these data have been published in Riche and Traverse (1970, 1971), Peet (1971), Murphy (1972), Traverse (1972, 1973), Murphy (1974), Pratt et al. (1974), Porter and Davis (1974), and Anderson (in preparation).

WEST BROOK
MIDDLE BROOK

River code 5213620/5213660

Counting Fence

West Brook and Middle Brook, known as Double Brook, are located in Labrador and flows south into Groswater Bay on the north side of Hamilton Inlet. The two streams drain about 475 km^2 and have a total stream length of 155 km.

In 1967, a counting fence of wood and wire mesh construction was installed on each stream. The purpose was to enumerate adult salmon and determine if they existed in sufficient numbers to permit smolt tagging. The project was undertaken in connection with the Greenland Salmon Fishery Investigation mentioned previously in the discussion of Sand Hill River operations and detailed by Peet (1971). The fences were operated for just one season during which time 144 grilse and 10 large salmon were enumerated. The most abundant fish were determined to be brook trout with 1368 recorded. A total of 690 Arctic charr were also observed at the fences (Table 81).

1967	14	1	219	34

FRASER RIVER River code 5321160

Counting Fence

Fraser River is located in northern Labrador (Fig. 1). It flows east into Nain Bay and drains an area of 1606 km^2 at its inlet to Tassiuak Lake. The main stem length including Tassiuak Lake is 172 km.

In 1975 to 1979, a counting fence was installed on Fraser River to gather biological data on Arctic charr. The study was initiated because of a rapidly escalating commercial fishery for this species in the northern Labrador area and the limited information on migration patterns, growth rates and exploitation rates that was available. Information from the counting fence and commercial fishery has been published by Coady and Best (1976), Dempson (1978) and Dempson and Best (1978). Only a brief summary of these data are given here. Data from 1976 and 1978 are incomplete due to the difficulties in maintaining the fence in position under wide fluctuation in water levels in this region (Table 82).

ACKNOWLEDGMENTS

To all the individuals who have counted, collected and carried Atlantic salmon at counting fences and fishways since 1949, your major contribution to the Atlantic salmon resource is acknowledged. The authors would like to thank; for editing N. Caines, D. Reddin, J. D. Pratt, and R. Porter; for drafting, H. Mullett; and for typing, K. Harding and J. Lannon.
