## Canadian Manuscript Report of Fisheries and Aquatic Sciences No. 1872

# Canadian Manuscript Report of Fisheries and Aquatic Sciences 

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-900 in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 901-1425 were issued as Manuscript Reports of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551.

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport manuscrit canadien des sciences halieutiques et aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais quitraitent de problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. Il n’y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications complètes. Le titre exact parait au-dessus du résumé de chaque rapport. Les rapports manuscrits sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annuel des publications scientifiques et techniques du Ministère.

Les numéros 1 à 900 de cette série ont été publiés à titre de manuscrits (série biologique) de l’Office de biologie du Canada, et après le changement de la désignation de cet organisme par décret du Parlement, en 1937, ont été classés comme manuscrits (série biologique) de l'Office des recherches sur les pêcheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de rapports manuscrits de l'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

Les rapports manuscrits sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

Shardlow, T. F., K. K. English, T. Hoyt, G. E. Gillespie and T. A. Calvin. 1989. Strait of Georgia Creel Survey sport fishery statistics, 1983. Can. MS Rep. Fish. Aquat. Sci. 1872: 53 p.

Catch and effort statistics for the Strait of Georgia tidal sport fishery are presented for each month in 1983. The statistics were derived by combining the data from over 26,000 interviews and 50 aerial surveys. Estimates were provided for the number of sport fishing boat trips and the catches of chinook, coho, and pink salmon along with rockfish, lingcod, dogfish and other finfish. Also given are numbers of marked (adipose fin-clipped) and unmarked chinook and coho examined during the creel survey, and the age composition of chinook catches. The appendix includes all catch and effort statistics for each month and Statistical Area combination.

Keywords: salmon, creel survey, sport fishing, catch, effort, age composition.

## RESUME

Shardlow, T. F., K. K. English, T. Hoyt, G. E. Gillespie and T. A. Calvin. 1989. Strait of Georgia Creel Survey sport fishery statistics, 1983. Can. MS Rep. Fish. Aquat. Sci. 1872: 53 p.

Les statistiques relatives aux prises et a l'effort de pêche de la pêche sportive de la zone tidale du détroit de Géorgie sont présentées pour chaque mois de 1983. Ces valeurs ont été obtenues en réunissant les données de plus de 26000 entrevues et 50 relevés aériens. On y trouve les estimations du nombre de sorties des bateaux de pêche sportive et des prises de saumons quinnat, coho et rose en plus de celles de scorpènes, d'ophiodon, d'aiguillat et d'autres poissons. Le nombre de saumons quinnat et coho marqués (coupe de la nageoire adipeuse) et non marqués examinés au cours des relevés des prises et la composition par age des prises de saumon quinnat sont aussi présentés. On trouve aussi en appendice toutes les statistiques relatives aux prises et à l'effort de pêche pour chaque mois et combination de zones statistiques.

Mots clés: saumon, releve des prises, pêche sportive, prises, effort de pêche, composition par ages.

## 1. INTRODUCTION

This report documents the 1983 catch and effort statistics for the Strait of Georgia sport fishery and discusses methodology for collecting these data. During the 1970 s , the sport fishery grew to be the largest harvester of chinook and coho salmon in the Strait of Georgia. Table 1 shows historical catch statistics for the Strait of Georgia sport fishery for the period 1960-1983. During this period, fisheries managers recognized the deficiencies in traditional methods of estimating sport catch and the need for accurate catch statistics. In 1980, the Georgia Strait Creel Survey Program was initiated to meet the need for accurate and timely sport catch statistics for chinook and coho. Since 1980, the objectives of the Creel Survey Program have been expanded to provide accurate estimates of sport catches of all finfish, and age and length composition of chinook catches. This report is one of a series of Georgia Strait Creel Survey Reports which document annual creel survey activities and estimation procedures, and provide official published Strait of Georgia tidal sport fishing catch statistics.

The 1983 creel survey gathered the most comprehensive set of annual sport fishing data for Strait of Georgia to date. The only project interruption occurred during April when no interviewing was done due to year-end staffing difficulties. However, aerial survey data were collected so that indirect estimates could be made for April.

### 2.0 METHODS

The Strait of Georgia Creel Survey is comprised of two independent surveys: angler interviews and aerial overflights. Angler interviews provide data on sport fishing catch per unit effort (CUPE) and daily activity patterns. Aerial overflights provide estimates of the total sport fishing effort in the study area at the time of the aerial survey. These data are combined to provide monthly estimates of total sport fishing effort and total catch of salmon and groundfish in the sport fishery. In its simplest form, estimated total catch is calculated by multiplying estimated total effort by catch per unit effort.

The design of the Strait of Georgia Creel Survey conducted in 1983 was similar to that used by DPA Consulting Ltd. (1982) with some modifications to the data analyzed, sampling intensity, flight routes and data processing. Sampling was conducted during each month of the year and estimates were produced for 10 time periods. January and February data were grouped together, as were November and December data because of reduced fishing activity and sampling in these winter months. Mid-week days and weekend days were considered independently because sport fishing activity is known to be quite different between the two types of days. The Strait of Georgia study area was also stratified by geographic region. Catch and effort statistics were produced for each of the 10 Statistical Areas within Georgia Strait (Areas 13 - $19 \mathrm{~A}, 19 \mathrm{~B}^{+}, 28$ and 29 , Fig. 1); Statistical Area $19 \mathrm{~B}^{+}$includes portion of Area 20 to Sheringham Point (See Appendix $B$ for a complete description of the study area).

a Source: Coho catch statistics: 1960-1978 from Argue et al. (1983), 1979 from R. Kadowaki (pers. comm.), 1980-1982 from Shardlow et al. (MS 1989).
Chinook catch statistics: 1960-1977 from Argue et al. (1983), 1978 and 1979 from B. Riddell (pers. comm.) following the methods of Argue et al. (1983), 1980-1982 from Shardlow et al. (MS 1989). Effort statistics: 1960-1979 from annual published and unpublished Fisheries Officer statistics, 1980-1982 from Shardlow et al. (MS 1989).

SUMMER OVERFLIGHT ROUTE

WINTER OVERFLIGHT ROUTE

Figure 1. Interview site locations, and summer and winter overflight routes, Strait of Georgia, 1983.

### 2.1 FIELD SURVEYS

### 2.11 Angler Interviews

Sport fishermen were interviewed at the end of their fishing trip to determine time spent fishing, locations fished and catch of each species on the trip. Demographic information was also collected during the interview. Figure 2 shows the interview form used in 1983.

Interviewers trained in fish identification inspected each boating party's catch. Unlike other methods of collecting sport fishery information, such as mail-in or telephone surveys, there was little memory-related recall bias, non-response bias, and fish identification concern with this approach to calculating sport fishery catch. Landed chinook and coho were checked for a missing adipose fin whichindicates the presence of a coded wire tag embedded in the fish nose cartilage. In addition, scale samples for age determination and measurements for none-fork length were taken during every sampling shift in the winter and every other shift in the summer. Five scales were removed from the INPFC (International North Pacific Fisheries Commission) preferred area of each biosampled chinook (Mosher 1968).

The interviews were conducted at 31 landing sites (boat ramps, marinas, or resorts, Fig. 1) representative of sport fishing activity in each Statistical Area. The number of sites selected in each area was dictated by targets of desired precision and number of survegors available. For each area - day type - work block stratum, sampling shifts at a site were chosen on a near random basis from the total number of shifts available. For definition of the above terms (day type, work block, shift) see Section 2.2 .

### 2.12 Aerial Overflights

Aerial surveys were conducted from float planes travelling along pre-defined routes which allowed observers to count vessels actively sport fishing throughout Strait of Georgia. Planes flew at an altitude of 500-700 feet to facilitate a broad range of vision and still allow easy identification of vessel characteristics. Each plane carried three observers, two on the right side and one on the left, and each observer counted sport fishing boats to his/her side of the flight path. Figure 1 shows the flight path used in 1983. The winter (October-April) flight path was slightly reduced to correspond with lower witner effort.

The flight path and time of departure were designed to cover major concentrations of sport fishing activity at peak periods. Whenever possible, the route was flown to keep most of the sport fishing boats to the right side to allow averaging of the two right side counts. To maximize precision, flying times during which fishing effort was rapidiy changing, were avoided. The number of overflights each month was governed by targets of desired precision and the expected number of interviews from the given number of sampling shifts. The days for overflights during a month were randomly selected for each day type.

Figure 2. Sample of 1983 interview form.

### 2.2. DATA ANALYSIS

The description of terms, variables and subscripts used in this report is given in Table 2.

### 2.21 Calculation of Catch and Effort Statistics

To estimate the monthly catch and effort, three components had to be calculated from that month's data:
(1) the weighted mean daily fishing pattern from interview data,
(2) the weighted mean catch per unit effort from interview data and
(3) the mean sport count from overflight data.

The equations used to estimate the means and variances for all catch and effort statistics are shown below. For April which had only overflight data, the interview data from preceding and following months were combined to estimate the mean daily fishing activity pattern and catch per unit effort. The catch and effort estimates for April are referred to as indirect estimates.

Weighting factors used to estimate the daily fishing activity pattern and mean catch per unit effort were calculated using the equations derived from DPA Consulting Ltd. (1982).

The data obtained from each shift were multiplied by the following weighting factor (Wl) to expand for all possible stints at each site. The formula reads:

$$
\begin{equation*}
W 1_{\mathrm{dij}}=\frac{\mathrm{N}_{\mathrm{d}}}{\mathrm{n}_{\mathrm{dij}}} \tag{1}
\end{equation*}
$$

where $N_{d}$ is the total number of days of type $d$ in that month and $n_{d i j}$ is the number of times the $j$ th work block at the $i$ th site was sampled on type d days.

The interviews aggregrated by work block were multiplied by the weighting factor $W$ 2 to expand for all boats that landed in each work block. The formula reads:

$$
\begin{equation*}
\mathrm{W} 2_{\mathrm{dijk}}=\frac{L_{\text {dijk }}}{\mathrm{I}_{\mathrm{dijk}}} \tag{2}
\end{equation*}
$$

where $L_{d i j k}$ is the number of boats landed and $I_{d i j k}$ is the number of boats interviewed on the $k$ th stint in the jth work block at the ith site on a day type d.

Therefore, the following equations can be used to calculate an unbiased estimate of the total monthly catch ( $\hat{C}_{d g r}$ ), fishing trips ( $\hat{T}_{d g}$ ) and fishing activity in time block $\hat{A}_{d g t}$ for each day type (d) where $g$ is a set of landing sites (i). These formulas read:

Table 2. Description of terms, variables and subscripts used in this report.
DESCRIPTION OF TERMS

DESCRIPTION OF VARIABLES

| A | - | Number of boats actively fishing |
| :---: | :---: | :---: |
| B | - | Number of boats observed on a fight |
| C | - | Catch |
| $C^{\prime}$ | - | Catch of marked salmon |
| CPE | - | Catch per boat trip |
| E | - | Effort (estimated total number of boat trips) |
| I | - | Number of boats interviewed and found to have been fishing |
| L | - | Number of boats landing |
| n | - | Number sampled |
| N | - | Population size from which n samples were observed |
| $\frac{\mathrm{P}}{\mathrm{T}}$ | - | Proportion |
| T | - | Number of boat trips |
| $\checkmark$ | - | Number found to be marked |
| W1 | - | Weighting factor to expand for all possible stints at each site |
| W2 | - | Weighting factor to expand for all boats that landed in each work |

DESCRIPTION OF SUBSCRIPTS

$$
\begin{align*}
& \hat{\mathrm{C}}_{\mathrm{dgr}}=\sum_{\mathrm{i}} \sum_{\mathrm{j}}\left[\mathrm{~W}_{\mathrm{dij}} \sum_{\mathbf{k}} \sum_{\mathrm{q}}\left(\mathrm{~W}^{\mathrm{dijk}} \mathrm{C}_{\text {dijklqq }}\right)\right]  \tag{3}\\
& \hat{\mathrm{T}}_{\mathrm{dg}}=\sum_{\mathrm{i}} \sum_{\mathrm{j}}\left[\mathrm{~W}_{\mathrm{dij}} \sum_{\mathrm{k}} \sum_{\mathrm{q}}\left(\mathrm{~W} 2_{\mathrm{dijk}}\right)\right]  \tag{4}\\
& \hat{A}_{\text {dgt }}=\sum_{i} \sum_{j}\left[W_{d i j} \sum_{k} \sum_{q}\left(W^{\text {dijk }} \text { A } \mathrm{A}_{\text {dijkqt }}\right)\right] \tag{5}
\end{align*}
$$

where $C_{d i j k g r}$ is the catch of species $r$ by the $q$ th fishing party, and $A_{d i j k q t}$ can equal o or 1 , thereby indicating whether the qth fishing party was actively fishing in time block $t$. Thus, the mean monthly catch per unit effort ( $C^{\prime} E_{d g r}$ ) measured in terms of numbers of fish kept per completed boat trip, and proportion of daily fishing effort active during the hour of the aerial survey ( $\mathrm{P}_{\mathrm{dg}}$ ) can be calculated with the following equations:

$$
\begin{align*}
& \mathrm{CPE}_{\mathrm{dgr}}=\frac{\hat{\mathrm{C}}_{\mathrm{dgr}}}{\hat{\mathrm{~T}}_{\mathrm{dg}}}  \tag{6}\\
& \mathrm{P}_{\mathrm{dgt}}=\frac{\hat{\mathrm{A}}_{\mathrm{dgt}}}{\hat{\mathrm{~T}}_{\mathrm{dg}}} \tag{7}
\end{align*}
$$

where $C P E_{d g r}$ and $P_{\text {dgt }}$ are calculated for each day type (d) and group of landing sites (g). The groups of landing sites reflect geographic areas with similar catch rates and/or activity patterns.

The estimated mean number of boats fishing during the hour of the sport boat count by overflight was calculated for each sub-Statistical Area using the following equation:

$$
\begin{equation*}
\bar{B}_{d s t}=\frac{\sum_{u} B_{d s t u}}{n_{d s}} \tag{8}
\end{equation*}
$$

where $B_{d s t u}$ is the number of boats observed fishing on flight $u$ at time $t$, in sub-Statistical Area $s$ for day type d.

The mean sport boat count at the time of the overflight ( $\bar{B}_{d s t}$ ) and proportion of daily fishing effort active during the hour of the overflight ( $P_{d g t}$ ) were used in the following equation to calculate the total fishing effort for sub-Statistical Area $s$ on day type $d$ :

$$
\begin{equation*}
E_{d s}=\bar{B}_{d s t} \frac{1}{P_{d g t}} N_{d} \tag{9}
\end{equation*}
$$

where $N_{d}$ is the number of type d days in the month. Interview data for the sub-Statistical Areas fished (s) by anglers landing at each of the sites (i) within a landing group (g) were used to select the proportions ( $\mathrm{P}_{\mathrm{dg}}$ ) that are appropriate for each mean boat count ( $\bar{B}_{d s t}$ ).

The estimate for total effort by sub-Statistical Area and day type ( $E_{d s}$ ) and the weighted catch per boat trip for a group of landing sites by day type, area and species ( $C_{P E}{ }_{d g r}$ ) were used to calculate total catch for each species ( $r$ ) and each sub-Statistical Area (s).

$$
\begin{equation*}
C_{s t}=\sum_{d}\left(E_{d s} C P E_{d g r}\right) \tag{10}
\end{equation*}
$$

The interview data were also used to select the catch per effort estimates ( $C_{P E} \mathrm{dgr}_{\mathrm{r}}$ ) that should be applied to the effort estimate ( $E_{d s}$ ) for a specific sub-Statistical Area (s).

### 2.22 Variance of Total Fishing Effort

The variance for estimates of total fishing effort has two components:
(1) the variance in aerial sport boat counts:

$$
\begin{equation*}
S_{B_{d s t}}^{2}=\frac{\sum_{u} B_{d s t u}^{2}-\frac{\left(\sum_{u} B_{d s t u}\right)^{2}}{n_{d s}}}{n_{d s}\left(n_{d s}-1\right)}\left[\frac{N_{d}-n_{d s}}{N_{d}-1}\right] \tag{11}
\end{equation*}
$$

where $B_{d s t u}$ is the aerial sport boat count at time $t$ during an aerial survey $u$ on a type d day in sub-area $s ; n_{d s}$ is the number of aerial surveys in which boats were counted on type d days, in sub-Statistical Area $s$; and $N_{d}$ is the total number of type d days in the month.
(2) the variance in the proportion of boats fishing during the hours of the aerial boat counts:

$$
\begin{equation*}
S_{P_{d g t}}^{2}=\frac{P_{d g t}\left(1-P_{d g t}\right)}{I_{d g}} \tag{12}
\end{equation*}
$$

where $P_{\text {dgt }}$ is the mean proportion of boats fishing for a group of landing sites $g$ during the hour of the aerial boat count $t$ on type d days, and $I_{d g}$ is the total number of sport fishing boats interviewed. The above formula assumes $P_{d g t}$ is unbiased and normally distributed where the number of interviews is large.

The variances for boat counts ( $\mathrm{S}^{2} \mathrm{~B}_{\mathrm{dst}}$ ) and proportion of boats fishing ( $S^{2} P_{d g t}$ ) were combined in the following equation to cas culate variance for effort:

$$
\begin{equation*}
S_{E_{d s}}^{2}=N_{d}^{2}\left(\frac{B_{d s t}^{2}}{P_{d g t}^{2}}\right)\left(\frac{S_{B_{d s t}}^{2}}{B_{d s t}^{2}}+\frac{S_{P_{d g t}}^{2}}{P_{d g t}^{2}}\right) \tag{13}
\end{equation*}
$$

where $S^{2} E_{d s}$ is the variance for total effort on type d days in sub-area $s$, and the formula is the standard formula for the variance of a ratio of two independent random variables.

### 2.23 Variance of Total Catch

The variance for estimates of total catch had two components: (1) the variance for total effort (presented above), and (2) the variance for catch per boat trip.

The variance for catch per boat $t r i p\left(S^{2} C P E_{d g r}\right)$ was calculated using the following equation:

$$
\begin{equation*}
\mathrm{S}_{\mathrm{CPE}_{\mathrm{dgr}}}^{2}=\frac{\mathrm{SS}_{\mathrm{CPE}_{\mathrm{dgr}}}-\frac{\left(\mathrm{S}_{\mathrm{CPE}_{\mathrm{dgr}}}\right)^{2}}{\mathrm{I}_{\mathrm{dg}}}}{\mathrm{I}_{\mathrm{dg}}\left(\mathrm{I}_{\mathrm{dg}}-1\right)} \tag{14}
\end{equation*}
$$

where $S_{C_{C P E}}{ }_{d g r}$ is the weighted sum of squares for $C P E_{d g r}$, and $S_{C P E}{ }_{d g r}$ is the weighted sum for $C P E_{d g r}$, such that the sum of the weighting factors used to estimate $C P E_{d g r}$ was equal to the number of interviewed boat trips ( $I_{d g}$ ).

The variance for total effort and the variance in the catch per boat trip for the appropriately grouped landing sites were combined in the following equation to calculate variance for total catch:

$$
\begin{equation*}
S_{C_{s r}}^{2}=\sum_{d}\left(E_{d s}^{2} S_{C P E}^{d g r}+C P E_{d g r}^{2} S_{E_{d s}}^{2}+S_{C P E_{d g r}}^{2} S_{E_{d s}}^{2}\right) \tag{15}
\end{equation*}
$$

which is the standard formula for the variance of the product of two independent random variables, and where $S^{2} C_{S r}$ is the variance for total number of species $r$ in sub-Statistical Area $s$.
2.24 Estimation of Marked Chinook and Coho Salmon

Incidence of marked (adipose-clipped) chinook and coho was recorded in each interview. The proportion of marks observed for each region, month and species ( $P_{\mathbf{x m r}}$ ) was calculated as:

$$
\begin{equation*}
P_{x m r}=\frac{V_{x m r}}{n_{x m r}} \tag{16}
\end{equation*}
$$

where $V$ is the number of marked fish observed and $n$ is the number of fish inspected by region(x), month(m) and species (r).

The variance of each proportion was calculated as:

$$
\begin{equation*}
S_{P_{x m r}}^{2}=\frac{P_{x m r}\left(1-P_{x m r}\right)}{n_{x m r}} \tag{17}
\end{equation*}
$$

Monthly catch estimates of marked salmon were calculated as:

$$
\begin{equation*}
C_{x m r}^{\prime}=P_{x m r} C_{x m r} \tag{18}
\end{equation*}
$$

where $C_{x m r}$ is the estimated catch of species $r$ in region $x$ and month $m$. The variance of the marked catch estimates was calculated as:

$$
\begin{equation*}
S_{C_{x m r}^{\prime}}^{2}=P_{x m r}^{2} S_{C_{x m r}}^{2}+C_{x m r}^{2} S_{P_{x m r}}^{2}+S_{C_{x m r}}^{2} S_{P_{x m r}}^{2} \tag{19}
\end{equation*}
$$

where $S^{2} C_{x m r}$ is the variance of the catch estimate of species $r$ in region $x$ and month $m$.

The estimated annual proportions of marked salmon caught in each region (weighted by the corresponding regional annual catch estimates) were calculated as:

$$
\begin{equation*}
P_{x r y}=\frac{C_{x r y}^{\prime}}{C_{x r y}} \tag{20}
\end{equation*}
$$

where

$$
\begin{equation*}
C_{x r y}^{\prime}=\sum_{m} C_{x m r}^{\prime} \quad \text { and } \quad C_{x r y}=\sum_{m} C_{x m r} \tag{21}
\end{equation*}
$$

The variance of the annual proportions was calculated as:

$$
\begin{equation*}
S_{P_{x r y}}^{2}=\left(\frac{C_{x r y}^{\prime}}{C_{x r y}}\right)^{2}\left[\frac{S_{C_{x r y}^{\prime}}^{2}}{\left(C_{x r y}^{\prime}\right)^{2}}+\frac{S_{C_{x r y}}^{2}}{\left(C_{x r y}\right)^{2}}\right] \tag{22}
\end{equation*}
$$

where $s^{2} C_{x r y}$ is the variance of the annual estimated catch of species $r$ in region $x$.
2.25 Estimation of Age Composition of Chinook Catch

Scale samples and length measurements were taken in a subsampling program during the interview process. Ages used in this report represent total age of the fish (including both freshwater and oceanic life) according to the Gilbert-Rich (1927) recording convention.

The proportion of chinook at each age and month ( $P_{\text {am }}$ ) was calculated as:

$$
\begin{equation*}
P_{a m}=\frac{a_{m}}{n_{m}} \tag{23}
\end{equation*}
$$

where $a_{m}$ represents the number of fish observed at age a during month $m$, and $n_{m}$ is the total number of fish biosampled in that month.

The variance of each proportion was calculated as:

$$
\begin{equation*}
S_{a m}^{2}=\frac{P_{a m}\left(1-P_{a m}\right)}{n_{m}} \tag{24}
\end{equation*}
$$

The catch at age of chinook in each month was calculated as:

$$
\begin{equation*}
C_{a m}=P_{a m} C_{m} \tag{25}
\end{equation*}
$$

where $C_{m}$ is the estimated catch of chinook salmon in a given month $m$. The variance of the catch at age estimate was calculated as:

$$
\begin{equation*}
S_{C_{a m}}^{2}=P_{a m}^{2} S_{C_{m}}^{2}+C_{m}^{2} S_{P_{a m}}^{2}+S_{C_{m}}^{2} S_{P_{a m}}^{2} \tag{26}
\end{equation*}
$$

where $S^{2} C_{m}$ is the variance of the monthly catch estimate $C_{m}$. The annual catch at age was calculated as:

$$
\begin{equation*}
C_{a y}=\sum_{m} C_{a m} \tag{27}
\end{equation*}
$$

with a variance

$$
\begin{equation*}
S_{C_{a y}}^{2}=\sum_{m} S_{C_{a m}}^{2} \tag{28}
\end{equation*}
$$

The annual proportion at age (weighted by monthly catch) was calculated as:

$$
\begin{equation*}
P_{a y}=\frac{C_{a y}}{C_{y}} \tag{29}
\end{equation*}
$$

with a variance

$$
\begin{equation*}
S_{P_{a y}}^{2}=\left(\frac{C_{a y}}{C_{y}}\right)^{2}\left[\frac{S_{C_{a y}}^{2}}{\left(C_{a y}\right)^{2}}+\frac{S_{C_{y}}^{2}}{\left(C_{y}\right)^{2}}\right] \tag{30}
\end{equation*}
$$

### 3.1 DISTRIBUTION OF SAMPLING EFFORT

Table 3 shows the number of creel survey interviews conducted by month and Statistical Area in 1983, and the number of monthly overflights. A total of 24,756 interviews ( 20,476 fishing interviews) and 50 overfiights were conducted in 1983. The monthly distribution of interviews reflected the monthly distribution of fishing effort (number of boat trips, Table 4, Fig. 3), except in April when no interviews but four aerial surveys were conducted. Interview effort was dramatically reduced during winter months, especially for Statistical Areas 13 , 14 and 15 in the northern portion of Strait of Georgia (Table 3). The total fishing interviews represented $3.6 \%$ of the estimated total fishing effort for the entire study area ( 574,257 boat trips, Table 4) and ranged in each Statistical Area from a low of $1.6 \%$ of the estimated total fishing effort in Area 13 to a high of $7.8 \%$ of the estimated fishing effort in Area 19B+ (Tables 3 and 5). The major reason for this difference was that the Area 19B+ fishing effort was concentrated through a small number of launch ramps allowing for more interviews to be held in a given time period, while the Area 13 fishing effort was distributed over a large number of interview sites.

### 3.2 SPORT FISHING EFFORT AND CATCH

Tables 4 and 5 summarize the 1983 Strait of Georgia sport fishing effort and catch statistics for each species by month and by Statistical Area, respectively. Fishing effort and catch statistics for each month and Statistical Area combination are provided in Appendix A.

Sport fishermen made 574,257 boat trips during 1983, which represents a $10 \%$ decrease in effort from each of the previous two years (Table 1). This change may be best attributed to the depressed economic situation. However, sport fishing effort has shown very similar seasonal trends for each of the years 1981 to 1983 (Fig. 4). Generally, winter effort consisted of about 10,000 boat trips per month. Fishing activity increased rapidly in May and peaked in June, July, and August to about 140,000 boat trips per month. This peak was followed by a sharp decline in October to low winter levels of fishing effort.

Chinook fishing improved in 1983 with anglers taking 198,433 fish (Tables 4 and 5) compared to 163,793 in 1982 (Table 1). Most of the chinook were landed in 1983 during June to October ( $81 \%$ of total, Table 4). Chinook catches were low in May 1983 compared to previous years, but increased steadily through the summer to reach the highest September chinook catch on record (Fig. 5, Table 4). Catch success for chinook (catch per boat trip) was highest during winter months with November/December fishermen averaging one chinook per boat trip (Fig. 6, Table 6). Summer catch success for chinook was higher in 1983 than in the previous three gears (Fig. 6). The highest chinook catches were taken in Area 13 ( $18.6 \%$ of total), Area 14 (18.5\%) and Area 19 B+ ( $15.2 \%$ ) (Table 5).

[^2]The 1983 coho catch of 404,031 pieces (Tables 4 and 5) represents a $7 \%$ decrease from 1982 when approximately 436,000 coho were landed (Table 1). This lower catch parallels the reduced fishing effort observed in 1983 (Fig. 4). Most of the coho were landed in 1983 during summer months, with $93 \%$ of the total catch taken during May through September (Table 4). In 1983, coho catches peaked earlier than usual, with the June catch being almost twice as large as in previous years (Fig. 7). However, August/September catches were below normal (Fig. 7). Similarly, coho catch success in 1983 reached a high of 1.5 fish per boat trip in June, then declined rapidly through August (Fig. 8., Table 6). The highest coho catches were taken in Area 13 ( $30.4 \%$ of total), Area 14 ( $26.8 \%$ ) and Area 16 ( $18.2 \%$ ) (Table 5).

In 1983, Strait of Georgia anglers caught approximately 55,000 pink salmon between June and October (Table 4). Significant pink catches were expected in 1983 because pink salmon returns to Strait of Georgia rivers (primarily the Fraser River) are much greater in odd numbered compared to even numbered years. Campbell River in Area 13, and Victoria to Sooke waters in Area $19+$ were responsible for $90 \%$ of the pink catch (Table 5).

The landings of other salmonids consisted mainly of chum and sockeye but also included steelhead and cutthroat trout. Statistical Areas 17 and 18 showed the highest catches of other salmonids during 1983 ( $37.5 \%$ of total, Table 5). Most of the annual catch was made in August and September (37.7\% of total, Tables 4). A large portion of the other salmonids caught in Area 18 were probably part of a major chum run returning to the Cowichan River.

Certain groundfish species are becoming increasingly popular with sport fishermen, as indicated by the 1983 catches of rockfish (Sebastes spp.) (209,099 pieces), and lingcod (Ophiodon elongatus) ( 73,800 pieces, Tables 4 and 5). The largest catches of these species in 1983 occurred in Area 16 where 41,954 rockfish and 20,048 lingcod were landed, followed by Area 13 where 37,206 rockfish and 16,134 lingcod were taken. A small sub-survey was conducted in the Campbell River area to determine the species composition of the rockfish caught by anglers. From this survey, $42 \%$ of the rockfish landed were identified as quillback (Sebastes maliger) and $35 \%$ as copper (Sebastes caurinus). The remaining rockfish were either yelloweye (Sebastes ruberrimus), black (Sebastes melanops) or canary (Sebastes pinniger). The greatest catches of other finfish occurred in Areas 17 and 18 , where 68,270 of the total 94,100 other finfish were caught (Table 5). Area 18 also had the largest dogfish (Squalus acanthias) landings with 1,244 fish taken (Table 5).

Rockfish and lingcod, the most frequently caught non-salmonid species, showed the highest catch success (CPE) during April and May 1983, and a relatively constant $C P E$ for the remainder of the year (Table 6). Since spring season has a relatively low catch success for salmon, Strait of Georgia anglers may direct more of their fishing effort toward non-salmonid species during these months.

The average number of salmonids and non-salmonids caught during each boat trip in 1983 was 1.2 and 0.7 respectively (Table 6 ). The salmonid catch success represents a similar or slightly better catch efficiency compared to 1981 and 1982 when 1.2 and 1.0 fish per boat trip respectively, were reported. Catch success for combined salmonid and non-salmonid finfish during 1983 was 1.8 fish per boat trip (Table 6).

Figure 7. Monthly coho catch estimates for the Strait of Georgia sport fishery, 1980-1983. Bars indicate $95 \%$ confidence limits.

Figure 8. Monthly coho catch per boat trip for the Strait of Georgia sport fishery, 1980-1983.

During the summer months (May - September) in $1983,67 \%$ of the landed chinook were taken in the northern region of Strait of Georgia - Statistical Areas 13 to 17 (Appendix A). The opposite was true in the winter months (January - April, October - December) when $58 \%$ of the chinook catch came from the southern region - Statistical Areas $18,19,28$ and 29 . During November and December, $60 \%$ of the chinook catch came from Victoria/Sooke waters in Statistical Area 19B+.

Throughout 1983, more salmon were landed and more effort was expended in Area 13 than in any other Statistical Area (Fig. 9, Table 5). Boaters fishing in Area 13 enjoyed an average catch of 1.5 salmon per trip, second only to the catch success in Area 16 where 1.6 salmon were taken per boat trip. Area 14 recorded the greatest number of salmon hooked and released (213,141), with Area 13 next at 201,036 pieces (Appendix A-7). These two areas have major coho fisheries characterized by the release of many sub-legal coho.

### 3.3 BIOLOGICAL DATA

### 3.31 Proportion and Catch of Marked Chinook and Coho

In 1983, 8,477 chinook and 13,298 coho were examined for adipose fin clip marks. Tables 7 and 8 show the observed numbers of marked chinook and coho respectively, by month and region. Data were presented by region since some Statistical Areas had insufficient numbers of fish examined for marks in some months, and these data were included with other Areas. Three regions were defined: the North Gulf represented by Areas 13-16; the South Gulf represented by Areas $17,18,28,29$ and the Saanich Inlet portion of Area 19 (Area 19A); and Victoria region represented by the remainder of Area 19 (Area 19 B+) (Fig. 1). Among chinook examined for marks, $2.6 \%$ had adipose fin clips. The largest observed proportion of chinook marks was in the North Gulf catch (0.042) and the lowest proportion in the Victoria catch (0.017) (Table 7). Among coho examined for marks, $4.2 \%$ had adipose fin clips. The largest observed proportion of coho marks was in the South Gulf catch ( 0.056 ), and the lowest proportion in the Victoria catch (0.022) (Table 8). Monthly catch estimates of marked chinook and coho are shown by region in Tables 9 and 10 respectively.

### 3.32 Catch-At-Age for Chinook

During $1983,1,656$ chinook biosamples were collected from 453 shifts for length and age analysis. Table 11 shows the number of chinook observed by age class each month in the sampled fish. The monthly percent age composition is summarized in Figure 10 and Table 12. The monthly age proportions were applied to the estimated monthly chinook catches to provide breakdown by age group (Table 13). In 1983, the majority of chinook sport catch in Strait of Georgia consisted of age 2 fish (57.1\%), followed by age 3 ( $25.5 \%$ ), age 4 ( $14.2 \%$ ) and age 5 or older (3.1\%).

Figure 10 and Table 12 show a shift in the age composition of chinook catch between the first five months and the remainder of the year. From January to May the catch was dominated by age 3 and 4 classes, which contributed $92.1 \%$ to that period's catch (Table 13). In June, age 2 class strengthened to 39.6\%

and remained the dominant age class for the remainder of the year with monthly contributions ranging between $48.7 \%$ and $92.0 \%$ (Table 12). The high proportion of age 2 chinook in June to December catches may be the result of 1 ) poorer than usual age 3 catches in the fall or 2 ) stronger than usual age 2 recruitment to the sport fishery. The latter is consistent with the findings of Argue et al. (1983) which show that age 2 chinook generally reach the minimum legal size limit of 45 cm in July.

### 3.33 Mean Length-At-Age for Chinook

Table 14 shows the mean nose-fork length by age for the 1,436 chinook for which both length and age data were available. These data are sumarized graphically in Figure 11. The largest portion of measured chinook ( 678 fish or $47 \%$ of the total sample) were in the $45-54 \mathrm{~cm}$ length category. This is consistent with the large catch of age 2 fish (Table 13) which were found to have an annual mean length of 49.1 cm (Table 14). Of the total sample, 101 fish or $7 \%$ were sub-legal in size (less than 45 cm ). The majority of these were landed at Brechin Point ( 34 fish ) and Westview ( 21 fish ). The largest chinook sampled were two fish each measuring 99 cm ; one was landed at Flemming Beach on July 16 and the other at Cheanuh Marina on September 9.

### 4.0 SUMMARY

The sport fishery creel survey was conducted in the Strait of Georgia in 1983 in order to estimate the catches of all important recreational finfish species and the total sport fishing boat trips. The number of chinook and coho salmon with adipose fin clips were also estimated. These data are presented by month and Statistical Area. Monthly age and length composition of chinook catch are also shown.

In 1983, a total of 24,756 boating parties were interviewed at 31 landing locations in the Strait of Georgia survey area. This sampling represents approximately $4 \%$ of the total number of boat trips conducted by sport fishermen in the Strait of Georgia in 1983. A total of 50 overflights were also conducted to take "snapshot" counts of fishing effort.

In 1983, sports fisherman landed an estimated 668,000 salmonids during 574,257 boat trips in Strait of Georgia; an additional 776,000 salmon were released by anglers. Landed salmon were identified as: 404,000 coho, 198,000 chinook, 55,000 pink salmon and 11,000 other salmonids (mainly chum, but also some sockeye, cuthroat, and steelhead trout). Ninety-five percent confidence limits for total catches of coho and chinook, and total fishing effort were within $7 \%$ of the corresponding estimated totals.

Among salmon examined for marks, $2.7 \%$ of chinook and $4.3 \%$ of coho had adipose fin clips. The majority of chinook sport catch in 1983 consisted of age 2 fish (57.1\%), followed by age 3 ( $25.5 \%$ ), age 4 ( $14.2 \%$ ) and age 5 or older (3.1\%). Of the total chinook measured in 1983 , $47 \%$ were $45-54 \mathrm{~cm}$ long, while $7 \overline{7}$ were sub-legal in size ( $\langle 45 \mathrm{~cm}$ ).

The total groundfish catch was 382,000 pieces or $36 \%$ of all finfish. Grounfish catches consisted of 209,000 rockfish, 74,000 lingcod, 4,500 dogfish and 94,000 other finfish.

### 5.0 ACKNOWLEDGMENTS

The authors wish to thank Lorne Collicutt, the creel surey staff and private marina and boat ramp owners for their valuable assistance and cooperation. We express our appreciation to the many thousands of anglers who participated in the interviews and creel checks. We also thank A. Y. Fedorenko for editing the report and Peggy Sutherland for typing the drafts.

APPENDIX C. STRAIT OF GEORGIA CREEL SURVEY STUDY AREA.

The Strait of Georgia Creel Survey study area includes those waters of Juan de Fuca Strait and the Strait of Georgia bounded in the south by a line from Sheringham Pt. on Vancouver Island due south to an intersection with the International Boundary and along the International Boundary to the B.C. Mainland coast at Blaine (Boundary Bay) and in the north by the following 3 boundary lines:

1) in discovery passage from Granite Pt. on Quadra Island to the stream mouth west of Moriarity Pt. on Vancouver Island.
2) in Okisollo Channel from Granite Pt. on Quadra Island due north to Sonora Island.
3) in Cordero Channel from Burnt Bluff on the mainland $214^{\circ}$ passing west of Dent Island to Sonora Island.

The area for which the Strait of Georgia Creel Survey statistics apply includes the above listed administrative area with the exception of the following areas:

1) Bute Inlet above a line from Lawrence Pt. running across the inlet. This area coincides with management units 13-21 and 13-22.
2) Waters of Pryce Channel, Waddington Channel, Pendrell Sound, Homfray Channel and Toba Inlet bounded by a line drawn from Horace Head on East Redonda Island at the south end of Waddington Channel to the northern point of Roscoe Bay on West Redonda Island and a line drawn within Homfray Channel from Price Pt. on the eastern shore of the channel by a line drawn from George Head at the easterly entrance of Ramsay Arm to Sutil Pt. on Cortes Island.
3) Hotham Sound above a line drawn from Elephant Point on the western shore of the Sound to the southern point of Granville Bay on the eastern shore of the Sound.
4) Jervis Inlet above a line drawn within Prince of Whales Reach from the mouth of Treat Creek on the east shore across the Reach to the summit (1625') at the head of Goliath Bay.
5) Sechelt Inlet including Narrows Inlet and Salmon Inlet above a line drawn within Skookumchuck Narrows from the "dog-leg" point southeast of the Egmont Pt. $224^{\circ}$ across the Narrows to Sechelt Peninsula.

[^0]:    a Includes chum, sockeye, steelhead and cutthroat trout.
    b A total closure for lingcod was in effect from January 1 to April 15 , and November 15 to December 31, 1983. Reported figures most likely represent illegal catches by anglers.
    c Indirect estimate.

[^1]:    a Includes chum, sockeye, steelhead and cutthroat trout.

[^2]:    a Calculated using Table 4 data.
    b Includes chum, sockeye, steelhead and cutthroat trout.
    c Indirect estimate.

[^3]:    aIndirect estimate.

[^4]:    a A total closure for lingcod was in effect from January 1 to April 15, and November 15 to December 31, 1983; see Table 4 footnote.
    b Indirect estimate.
