Canadian Technical Report of Fisheries and Aquatic Sciences No. 1474

## Canadian Technical Report of Fisheries and Aquatic Sciences

Technical reports contain scientific and technical information that contributes to existing knowledge but which is not normally appropriate for primary literature. Technical reports are directed primarily toward a worldwide audience and have an international distribution. No restriction is placed on subject matter and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Technical reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-456 in this series were issued as Technical Reports of the Fisheries Research Board of Canada. Numbers 457-714 were issued as Department of the Environment, Fisheries and Marine Service, Research and Development Directorate Technical Reports. Numbers 715-924 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Technical Reports. The current series name was changed with report number 925.

Technical reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport technique canadien des sciences halieutiques et aquatiques

Les rapports techniques contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui ne sont pas normalement appropriés pour la publication dans un journal scientifique. Les rapports techniques sont destinés essentiellement à un public international et ils sont distribués à cet échelon. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports techniques peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaquę rapport. Les rapports techniques sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annual des publications scientifiques et techniques du Ministère.

Les numéros 1 à 456 de cette série ont été publiés à titre de rapports techniques de l'Office des recherches sur les pêcheries du Canada. Les numéros 457 à 714 sont parus à titre de rapports techniques de la Direction générale de la recherche et du développement, Service des pêches et de la mer, ministère de l'Environnement. Les numéros 715 à 924 ont été publiés à titre de rapports techniques du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 925.

Les rapports techniques sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

Gould, A.P., and A.P. Stefanson. 1986. The return of chum salmon stocks to the Johnstone Strait - Fraser River Study Area, 1978-82. Can. Tech. Rep. Fish. Aquat. Sci. 1474: 66 p .

The 1978-1982 catch, escapement and harvest patterns for Study Area chum salmon are reviewed and compared with previous years. Details of area histories, regulations, and effort as well as catch and escapement, production and test fishing information are presented.

For the five year period under review, 1978 had the highest catch, escapement and total stock size with 1982 recording the greatest exploitation rate.

Several trends in the catch and total return of Study Area chum are apparent from this review of annual cycles. The heaviest exploitation of chum occurs in Areas 12 and 13 with $81 \%$ of all catch coming from this region. The commercial fishery is predominantly seine with an average of over $70 \%$ taken with this gear during the 1978-1982 period. Higher than average returns and harvests are recorded for even years.

Catches of Fraser River chum outside the Area 29 terminal fishery increased during the period and makes interception of the Fraser River stocks a primary management concern. Catch of Mid Vancouver Island (Big Qualicum Project) enhanced chum become an increasingly larger component of the Johnstone Strait commercial fishery and contributed significantly even in years of generally poor harvest.

Key words: Chum salmon, Johnstone Strait, Fraser River, catch, escapement exploitation.

## RESUME

Gould, A.P., and A.P. Stefanson. 1986. The return of chum salmon stocks to the Johnstone Strait - Fraser River Study Area, 1978-82. Can. Tech. Rep. Fish. Aquat. Sci. 1474: 66 p.

On examine les prises, les modes de remonte et de pêche entre 1978 et 1982 pour le saumon kéta dans le secteur étudié et on les compare aux années précédentes. On présente des informations concernant la pêche d'essai, la production, les prises et la remonte de même que des détails sur les conditions antérieures, les réglements et l'effort de pêche dans ce secteur.

Pour la péiode de cinq ans considérée, c'est en 1978 que les prises de même que la remonte et la taille totale des stocks ont été les plus élevées, le plus haut taux d'exploitation tant enregistré en 1982.

A partir de cet examen des cycles annuels, on voit plusieurs tendances dans les prises et le nombre total de saumons kétas revenant frayer dans le secteur étudié. L'exploitation la plus forte de saumons kétas a été enregistrée dans les zones 12 et $13,81 \%$ de toutes les prises venant de cette région. La pêche commerciale s'est faite surtout à la seene, plus de $70 \%$ des prises ayant été capturées en moyenne àl'aide de cet engin entre 1978 et 1982 . On enregistre pour les années paires une remonte et une récolte plus élevées que la moyenne.

Les prises de saumons kétas du fleuve Fraser, à part la pêche en estuaire dans la zone 29, ont augmenté au cours de la période et ont fait de l'interception des stocks du fleuve Fraser une question primordiale de gestion. Les prises de samons kétas mis en valeur au centre de l'ile Vancouver (projet Big Qualicum) deviennent un élément de plus en plus important de la pêche commerciale dans le détroit de Johnstone et ont contribué de façon importante au succés de la pêche méme dans les années où la récolte était généralement faible.

Mots-clés: saumon kéta, détroit de Johnstone, fleuve Fraser, prise, échappée, exploitation.

## INTRODUCTION

For the purpose of analysing and managing chum stocks in the Southern Coastal area of British Columbia, a Study Area has been established in the Johnstone Strait and Georgia Strait regions. The Johnstone Strait-Fraser River Chum Salmon Study Area is divided into 13 sub-areas with approximately 120 tributary streams contributing to the chum salmon harvest. Figure 1 details the location of the Study Area and division by sub-area.

Since 1961, the status of the Study Area chum salmon stocks has been evaluated and reported annually in the Fisheries and Marine Services Technical Report Series and subsequently in the Canadian Technical Reports of Fisheries and Aquatic Sciences. These past reports summarized the chum returns for catches and escapements, forecasted the levels of future abundance and made recomendations. for conservation requirements and total allowable catch for the following seasons.

Figure 1. Location map of the Johnstone Strait - Fráser River Chum Salmon Study Area.

This report summarizes the annual forecasts and seasonal reviews from 1978-1982 with comments on trends over the five year period of observation. Predicted returns based on brood year cycle escapements and harvest objectives compared with actual catch and escapement data is discussed. Data are reviewed in terms of an evaluation of progress towards the long range goal of rehabilitating Study Area escapements. Details of fishing times, effort and management regulations developed in consultation with the Johnstone Strait/Georgia Strait/Fraser River Chum Salmon Advisory Committee are presented. (Appendix A).

## 1978-1982 SEASONAL REVIEW

## STUDY AREA FISHERY

Catch records, compiled by week, gear and statistical area are summarized in Appendix $B$ and $C$. Numbers of days fished are detailed in Appendix $A$ and $E$.

Prior to the season, expectations are developed each year based on brood year escapements, previous years' catches by age class, environmental indicators and average returns to escapement (Anderson, 1974). Escapement objectives for each year reflect the Department of Fisheries and Oceans escapement goals adjusted with consideration for each year's expected total return. It should be noted that there is a minor harvest component in years of no commercial harvesting due to test fishing and incidental catch in other fisheries. Table l summarizes the anticipated returns for the total Study Area, sub components for the Fraser River and Big Qualicum River Project chum and the overall Study Area escapement requirements, 1978-1982.

## Forecasts

For 1978, an average return of $2,395,000$ chum had been projected for the Study Area. The Fraser River and Big Qualicum River runs were expected to total 914,000 and 150,000 respectively. A moderate fishery was proposed for Johnstone Strait and the Fraser River. The proposed regulations for the projected returns were developed to provide a catch of 0.6 million and an escapement of about 1.8 million chum salmon.

Table 1. Forecasts for Study Area chum returns, 1978-1982.

| Year | Total <br> Expected Return | Fraser R. <br> Component | B. Qualicum R. <br> Component | Escapement <br> Objectives |
| :---: | :---: | :---: | :---: | :---: |
| 1978 | 2395000 | 914000 | 150000 | 1800000 |
| 1979 | 1205000 | 381000 | 160000 | 1500000 |
| 1980 | 1617000 | 595000 | 207100 | 1625000 |
| 1981 | 1895000 | 628000 | 225000 | 1700000 |
| 1982 | 2863000 | 890000 | 282000 | 1990600 |
| AVERAGES: | 1995000 | 681600 | 204820 | 1723120 |

NOTE: Fraser R. and Big Qualicum R. Components Included in total return.

Below average returns were predicted for 1979-1981. It was expected total returns for these years would not exceed escapement requirements and interception fisheries in Johnstone Strait and the Fraser River were not anticipated. A return of $1,205,000$ chum salmon for 1979 was projected for the Study Area. The Fraser River and Big Qualicum River runs were expected to total only 381,000 and 160,000 respectively. In the past, escapements on the order of 2.0 million produced optimum harvests and the long term objective has been to rehabilitate Study Area escapements to this level. The escapement objective for 1979 was 1.5 million, which was 300,000 more than the total expected return. In spite of this anticipated shortfall, minor harvests of enhanced Big Qualicum stock were expected in the Mid Vancouver Island area.

In 1980 a below average return of $1,617,000$ chum salmon had been projected for the Study Area. The Fraser River and Big Qualicum River components of this run were expected to total 595,000 and 207,100 respectively. The proposed escapement requirement for 1980 was $1,625,000$ which was greater than the expected return. In view of the inadequate expected stock strength, no fisheries were proposed for Johnstone Strait, however harvesting was anticipated in the Mid Vancouver Island area for Big Qualicum stocks.

A total return of $1,895,000$ was projected for 1981 , including 628,000 Fraser River and 225,000 Big Qualicum chums. The proposed escapement requirement was $1,700,000$ million chums, providing no opportunity for a chumdirected harvest. Surpluses to the Big Qualicum River project were expected to be harvested terminally.

For 1982, an above average return of $2,863,000$ was forecast for the Study Area. Included in this return was 890,000 Fraser River and 282,000 Big Qualicum River chums. Escapement objectives for 1982 totalled $1,990,600$ chum resulting in a predicted catch of 872,000 .

Table 2 details the total annual chum harvests by area for 1978-1982. Total Study Area catches by gear type are identified in Table 3.

## Catch

1978
The 1978 catches in the Study Area fishery totalled $1,476,619$ chum, the third largest catch since the re-start of the fishery in 1967 and significantly higher than the brood cycle year catch in 1974 . Of this catch $84.7 \%$ was taken in Johnstone Strait, $8.4 \%$ in the Fraser River and the balance in the Mid-Vancouver Island fishery. Of the total catch, $73.8 \%$ was taken by purse seine and $25.6 \%$ by gillnets. The total catch was approximately 900,000 more than the expected catch of 600,000 , primarily due to an increase in the expected rate of return to the Study Area.

## 1979

Although no commercial fishery was forecast for the 1979 season, there was a catch of 120,186 chum recorded for the year. This harvest was lower than the 1975 cycle year and the lowest since 1971. Areas 12 and 13 yield $87.8 \%$ of the total catch, the Fraser River area $6.5 \%$ and the Mid Vancouver Island fishery

| 1978 | 1476619 | 377470 | 25.6\% | 1090001 | 73.8\% | 9148 | 0.6\% |
| 1979 | 120186 | 26431 | 22.0\% | 90263 | 75.1\% | 3492 | 2.9\% |
| 1980 | 861958 | 233019 | 27.0\% | 625579 | 72.6\% | 3360 | 0.4\% |
| 1981 | 164342 | 69459 | 42.3\% | 93229 | $56.7 \%$ | 1654 | 1.0\% |
| 1982 | 1469921 | 437781 | 29.8\% | 1028493 | 70.0\% | 3647 | 0.2\% |
| AVERAGE: | 818605 | 228832 | 28.0\% | 585513 | 71.5\% | 4260 | 0.5\% |

$5.5 \%$ of the total catch. Seine catches accounted for $73.8 \%$ of catch with gillnets capturing $22.0 \%$. The majority of the catch ( $47.1 \%$ ) was taken prior to the third week in September during fisheries directed at Fraser River pink salmon occurring in Areas 12 and 13 . There were no chum-directed fisheries after the third week in September in Johnstone Strait or the Fraser River. Harvests after this date resulted from test fishing activities and a minor cleanup fishery for Big Qualicum River chum.

1980

The forecast of fishery closures for the 1980 season was revised after a greater than anticipated return of chum to the Study Area. Harvesting occurred in both Johnstone Strait and the Fraser River areas. However, the total catch of 861,958 was lower than the 1976 cycle year. As in pervious years the largest proportion, $81.8 \%$ of the catch, was taken in Areas 12 and 13 . The Fraser River and Mid Vancouver Island catch components were $8.8 \%$ and $9.4 \%$ respectively. Purse seines accounted for $72.6 \%$ of the total Study Area catch and $27.0 \%$ by gillnets.

## 1981

In 1981 a predicted low return of chum salmon dictated no interception fisheries would take place in the Johnstone Strait and Fraser River areas. Study Area harvesting for this year resulted from early season catches, test fishing and the terminal fishery in Area 14. Catches totalled 164,342 and were similar to the cycle year of 1977. The proportion of catches from Areas 12 and 13 dropped to $60.8 \%$ with almost $33.0 \%$ of Study Area catch taken in the Area 14 fishery. Area 29 fishery catches totalled $5.3 \%$ of the total Study Area catch. During the 1981 commercial season, the seine catch for the Study Area accounted for only $56.7 \%$ of the Area total. Gillnet catches rose to $42.3 \%$ of the total due to the limited magnitude of the total catch and the primarily gillnet only early fishery in the Mid Vancouver Island area. As in 1979, a higher than average percent of the chum catch came from the early September Fraser River pink fishery in Johnstone Strait, with $48.0 \%$ of the total catch for the 1981 season taken before the 3 rd week in September.

## 1982

Extensive fisheries took place in all harvest areas in 1982. The total chum catch was $1,469,921$, very similar to the 1978 cycle year catch. Approximately $80 \%$ of the total Study Area catch occurred in Areas 12 and 13 , the Fraser River fishery accounting for only $4.3 \%$ and harvesting of Big Qualicum River stock produced $13.4 \%$ of the total catch. Purse seines harvested a total of $70.0 \%$ with $29.8 \%$ caught in the gillnet fishery.

From the data in Table 2 , it is apparent that the majority of Study Area commercial catches are from Areas 12 and 13 with a combined 1978-1982 average of $81.4 \%$. Table 3 indicates that for the $1978-1982$ period an average of $71.5 \%$ of commercial catch was taken by purse seine, $28.0 \%$ by gillnet and less than $1.0 \%$ by troll. The distribution of catches within the Study Area has shown some shift between areas. Whereas Areas 12 and 13 have been consistent in harvest, the catch from Area 14 has become a larger percentage ( $10.7 \%$ ) of total Study Area harvest and the terminal Fraser River component has declined to an average
of $6.8 \%$. All areas considered, Area 12 has the highest harvest share with an average harvest rate of $48.2 \%$ of total Study Area catches.

## FRASER RIVER FISHERIES

The expected total return of Fraser River chums for the years under review has been presented (Table 1). Catches of Fraser bound chum salmon in Johnstone Strait, the United States Point Roberts area and in the Fraser River are calculated according to the method of Palmer (1972) and separation is based on run timing and proportion of total stock. Table 4 presents catch by area data, 1967 to 1982. In reviewing expected total stock returns with actual returns from Table 1 , only in 1978 and 1980 were actual returns in excess of predicted stock size.

It is of interest to compare the distribution of catch of Fraser River chums within the Study Area in years of chum-directed harvests. Prior to 1978 the percentage of Fraser River chum catch in the Fraser River and Point Roberts fisheries averaged $29.6 \%$ and $16.5 \%$ respectively. During the five year period under review, the proportions of catch in the Fraser and Point Roberts fisheries have declined to $16.6 \%$ and $12.2 \%$. The increase in the catch of Fraser River chums in interception areas outside the Area 29 fishery prior to a reliable assessment of total run size is a significant and continuing management problem.

## MID VANCOUVER ISLAND FISHERIES

The Mid Vancouver Island fishery is unique in the Study Area as it relies heavily on enhanced stocks from local hatcheries. The Big Qualicum River project is the predominant stock within the local fishery (Area 14). Major enhancement efforts for chum salmon on the Little Qualicum and Puntledge Rivers were initiated in the late $1970^{\prime}$ s with the first significant returns expected in 1984. The average return for $1978-1982$ of Big Qualicum River stock was approximately 235,600 with an average catch of 127,100 chum.

Total catch by area of Big Qualicum River stocks is presented in Table 5 for the years 1978-1982. Catches in Areas 12 and 13 are calculated from fin clip mark rates recovered by the Mark Recovery Program (MRP) and back calculated to the total catch (D. Bailey, pers. comm.). Detail of catch, effort and days fished for Area 14 is available in Appendices B and E.

## ESCAPEMENT

## Study Area Escapement

Sub-area escapement totals are detailed in Table 6 for 1978-1982 with comparisons to 1970-1979 and 1960-1969. Appendix D lists escapements for the same periods by individual streams. Estimates of Fraser River escapements are based on test fishing indices related to on-the-grounds observations. Fraser River mainstem spawner estimates are determined as an unvarying and fixed component of the total Fraser chum escapement.

1978
The 1978 chum escapement to Study Area streams of $1,629,600$ was less than the 1.8 million anticipated but exceeds the average recorded during the 1970's.

Table 4. Catch, Escapement, Total Stock and Exploitation of Fraser River Chum.

| GRAND TOTAL | 1521.5 | 1433.4 | 1408.3 | 848.3 | 1629.6 | 1310.4 | 882.7 |

On a sub-area basis, escapements to the Loughborough/Bute Inlet and Mid-to-Lower Vancouver Island were considered to be adequate, while escapement levels to all other sub-areas were below the spawning requirements. The Fraser River escapement, while below 0.5 million, was higher than any previous year.

1979
For 1979 the total spawning of 848,300 chums was well below predictions and less than the recent 10 year averages. The escapement provided inadequate numbers to all sub-areas, with the usually productive Mid Vancouver Island streams returning only $70 \%$ of estimated capacity. This escapement compares with the 1975 brood cycle year total of 750,000 .

1980
There were above average spawning returns totalling $1,408,300$ million in 1980, although this remained 0.2 million short of the 1.6 million escapement objective. On a sub-area basis, only escapements to Loughborough/Bute Inlet and Howe Sound were considered to be adequate. These two areas actually exceeded their estimated capacity by approximately $30 \%$. All escapements to area streams exceeded annual escapements for the previous year, with the exception of the Bond-to-Knight Inlet area.

1981

The escapement of $1,433,400$ chums to Study Area spawning streams in 1981 exceeded the escapement average for 1970-1979. This escapement was similar to the 1977 brood year escapement of 1.38 million. On a sub-area level, only escapements to the Loughborough/Bute Inlet sub-area were considered to be adequate. The Study Area as a whole, however, realized $57 \%$ of spawning capacity ranking the 1981 season third highest for the five year period under review.

## 1982

Escapement objectives for 1982 were set at approximately 2.0 million. Actual escapements fell short of this goal with only 1.52 million spawners enumerated. Although above the escapement average for 1970-1979, adequate escapement occurred only in the Loughborough/Bute Inlet area and Mid Vancouver Island.

Average escapement for the period 1978 to 1982 was 1.37 million compared with the 1970-1979 average of 1.31 million and the 1960-1969 average of 0.88 million. With the exception of the poor returns in 1979, the general trend of escapements from the 1960 's is increasing. If the current pattern continues, rehabilitation to the escapement goal of 2.0 million chums would be achieved before the year 2000 .

## Fraser River Escapements

The optimum chum spawning capacity for the Fraser River system was set at 500,000 during $1978-1981$ and revised upward to 700,000 in 1982 as a result of further study (M. Farwell, pers. comm.). Escapements to the Fraser River fell short of required spawning in each of the five years reviewed with the lowest
escapement of 302,200 occurring in 1979. The Chehalis, Harrison, Vedder, Stave and mainstem systems account for most of the spawning activity. The average escapement for $1978-1982$ was approximately 408,000 , ranking this period below the average for the preceeding 10 years of Fraser River observation.

## Big Qualicum River Escapement

Big Qualicum River escapements for the $1978-1982$ averaged 108,600 chum. Escapement requirements for the Big Qualicum River facilities were 125,000 until 1980 when objectives were lowered to 90,000 as a result of S.E.P. fry density/optimum production reviews. For the review period, the Big Qualicum escapements averaged $47 \%$ of the total escapement for the Mid Vancouver Island subarea.

## STOCK SIZE AND SUMMARY

Figure 2 presents the annual escapement in relation to total stock size, 1970-1982. Table 7 details the catch, escapement, total stock and harvest rate for each season, 1970-1982.

Table 7. Canadian commercial catch, escapement and percent exploitation of Study Area chum, 1970-1982.

| YEAR | CATCH | ESCAPEMENT | TOTAL RETURN | $\%$ <br> EXPLOIT |

Note: Catch does not include harvest of Canadian chum salmon in U.S. fisheries.

The 1978 return of chum salmon to the Study Area totalled $3,106,200$, approximately 725,000 more than the pre-season forecast and 757,000 greater than the 1970-1977 average return. From this higher than average return a harvest of $1,476,619$ was taken, representing a $47.5 \%$ exploitation rate. The 1978 total catch and exploitation rate compared with the 1970-1977 averages (Table 7) indicates a harvest 300,000 above this average and an exploitation rate approximately $6 \%$ higher than the average rate for the base period.

1979
Forecasted returns for 1979 were $1,205,000$ based on cycle brood year escapement in 1974-1976. No commercial fishery was anticipated for this season due to low expectations. Total actual returns for the Study Area in 1979 were only 968,500 , representing a $19.6 \%$ shortfall from the pre-season prediction and only $41 \%$ of the 1970-1977 average of $2,332,163$. The total catch of 120,186 from this below average return represented a harvest rate of only $12.4 \%$ and was comprised of early season catches in Johnstone Strait and the Fraser River combined with test fishing catches.

## 1980

Poor pre-season expectations suggested no chum-directed fisheries in 1980 . However, the total return of $2,270,300$ chum was only slightly less than the 1970-1977 average and over $29 \%$ above the pre-season forecasts. The commercial harvest for the 1980 season totalled 861,958 chum, $15 \%$ below the 1970-1977 average but slightly higher than the average for the period under review. This harvest represents a $38 \%$ exploitation rate and was below the 1970-1977 average of $43 \%$.

## 1981

Again, for 1981, a predicted return of 1.8 million and an escapement objective of the same number suggested no harvestable surplus. Consequently, no commercial fishery was planned for the season. Actual returns were even less ( $11 \%$ ) than forecast with $1,597,700$ chum returning to spawn in Study Area streams. This less than forecasted return was also below the 1970-1977 average by approximately 733,000. Pre-season non chum-directed catches accounted for most of the 164,342 harvest, matching the trend towards low catch in odd year fisheries and well below the 1970-1977 and 1978-1982 averages.

## 1982

Based on cycle brood year calculations, above average returns of $2,860,000$ were forecast for the 1982 season. The observed return of $2,991,400$ fish exceeded the pre-season prediction by $5 \%$. This return, the second highest of the 1978-1982 period was $28 \%$ above the $1970-1977$ average. Although the rate of exploitation for 1982 ( $49 \%$ ) was the highest exploitation rate since 1973 , total escapement was also above the recent 10 year average and the second highest for the five year period under review.

Table 2 indicates the distribution of catches by sub-area and gear for the five year period under review. From these data it is evident that the majority of Study Area commercial catches were taken from Area 12, Upper Johnstone Strait. The catch proportion from this sub-area ranged from $45 \%-70 \%$ of all Study Area chum catch for the $1978-1982$ seasons. Areas 12 and 13 combined accounted for an average of over $81 \%$ of all Canadian commercial Study Area catch. Distribution of catches by gear in Table 3 indicate the Study Area chum fishery is predominantly seine with minimal catch in the troll fishery. Seine catches averaged $70 \%$ in the commercial fishery for the $1978-1982$ seasons. Commercial gillnet fisheries averaged $28.0 \%$ of the total Study Area catch for the five year period under review with most of the gillnetting activity occurring in the Fraser River, Area 14 (Qualicum) and occasionally Area l6 (Bute Inlet).

Within the five year review period, 1978 had the highest catch, escapement and total return. The lowest catch, escapement and return were recorded in 1979. Table 7 illustrates the trend towards reduced exploitation rates in years with low returns. This odd/even year cycle of abundance, a possible result of competition between pink and chum juveniles (Beacham and Starr, 1982) is an apparent Study Area trend showing average even year returns exceeding average odd year returns. For the $1978-1982$ period, even year catches averaged $1,269,500$ chum while odd year catches averaged only 142,250 . The same review of data for 1970-1982 suggests the same pattern of larger even year catches.

Escapement averages were less disparate indicating an attempt to rebuild stocks even in years of low return. Even year escapements averaged 1,519, 800 while odd years averaged $1,140,850$ chum spawners. Total returns for even years averaged $2,789,300$ Study Area chum, while odd year returns averaged less than half this number at $1,283,100$. There is also a significant difference between exploitation rates for even and odd year seasons with a $46 \%$ average harvest rate for 1978 , 1980 and 1982 and an $11 \%$ average for 1979 and 1981. Although not as pronounced, a comparison of exploitation rates from $1970-82$ suggests odd year exploitation is lower than for even years.

Table 8 outlines the total production of Study Area chum for the 1960 thru 1977 brood years. For those years an average escapement of $1,135,904$ chums resulted in a total average production of $1,852,100$ chums or a return to escapement ratio of 1.83. The average three year old production for all years is $24.8 \%$. Of note is the significant difference between the odd and even year brood escapement, total return and most importantly the ratio of return to escapement.

During the period of review it appears that below average escapements in 1975 (754, 100) and 1976 ( $1,287,900$ ) apparently resulted in reduced Study Area productivity for the $1978-1982$ period. A factor limiting the total production and hence rehabilitation of Study Area chum was the generally lower return to escapement ratio exhibited in the mid 1970's. This ratio averaged 1.97:1 for 1960-1972 brood years and dropped to $1.46: 1$ for the brood years of the 5 year period under review (1973-1977). This reduction in the return:escapement ratio reduced the $1960-1977$ brood year return:escapement ratio to $1.83: 1$.

| 1981 | 1433400 |  |  |  |  |  |  |
| 1982 | 1521500 |  |  |  |  |  |  |

AVERAGES:

| 1960-1982: | 1135904 | 378715 | 1478568 | 119307 | 1930180 | $24.8 \%$ | 1.83 | $: 1$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| EVEN: | 1299242 | 392831 | 1891613 | 143803 | 2402301 | $18.2 \%$ | 1.97 | $: 1$ |
| ODD: | 957718 | 364599 | 1019629 | 94811 | 1458059 | $31.3 \%$ | 1.69 | $: 1$ |

The difference between even and odd year return to escapement are even more pronounced within the period of review. Even brood years (1974 and 1976) had an average return:escapement ratio of $1.92: 1$ while odd brood years (1973, 1975 and 1977) had an average return to escapement productivity ratio of 1.17:1. The apparent difference in overall productivity between even and odd years combined with a general trend of lower escapements in odd year would suggest different management strategies may be required for odd and even years.

## TEST FISHERY

Test fishing for abundance of migrating fall chum is undertaken in southern British Columbia each year. . Test purse seine assessments for total Study Area chum stock abundances are conducted in Areas 12 and 13 (Gould and Hop Wo, 1986). An in-river gillnet chum test fishery is located in the Fraser River for the assessment of. escapement abundance of Fraser chum (Farwell, 1985). For the Johnstone Straits test fishery, Anderson (1975) outlines the analysis of test catch data and the basic method for in-season estimation of stock abundance. Table 9 summarizes average test fishing catches by week for Areas 12 and 13, 1978-1982 with details provided in Appendix $F$. As well as determining abundance, test fishing scale samples in the upper Johnstone and lower Johnstone Strait areas are used to establish the age class structure for the annual return. Farwell (1985) details the application of Fraser River test fishing data to the assessment of total stock returns. Age class data is also collected from test fish samples in the Fraser.

## Age Class Structure

Data on the age class structure of Study Area chum salmon is collected each year from the test fishery in Johnstone Strait and commercial harvests. Table 10 presents yearly age class data for the Study Area returns as they enter the upper portion of Area 12. Weekly samples are weighted by weekly relative abundances as observed in the test fishery to obtain the annual age structure (Gould and Hop Wo, 1986).

The data in Table 10 illustrates that age composition of annual returns of chum salmon to the Study Area tend to fluctuate from year to year. Reviewing age class data averaged for all years suggests 3 year old production in any year to be just less than $30 \%, 4$ year old of approximately $65 \%$ and 5 year old at $5 \%$. Separating the data by odd and even year production illustrates a substantial shift in the age class structure for 3 and 4 year old return rates. The odd year production shows an increased 3 year old component which is an artifact of the overall large total return from even year production showing up as 3 year old returns in odd years (Table 10).

Table 9. Averages catch summary of upper \& lower Johnstone Strait (Area 12 \& Area 13) chum test fishing, 1978 - 1982.

Upper Johnstone Strait, Area 12.

The authors wish to thank District Supervisors, Norm Lemmen, Dennis Brock, Kip Slater, Grant Scott and Don Aurel who along with their staff provided much of the data used within. Don Anderson and Colin McKinnon provided in-season management support during the 1978 and 1979 seasons. The report was edited by Judy Barnetson and Jim Lettic. Shelley Doering typed the text.

Morley Farwell provided the data for the Fraser River area as well as ably contributed to management of the total Study Area.
