#### Abstract

Schubert, N.D. 1992. Angler effort and catch in five Fraser River chinook salmon sport fisheries, 1989. Can. Manuscr. Rep. Fish. Aquat. Sci. 2128: 69p.

The retention of chinook salmon (Oncorhynchus tshawytscha) adults in Fraser River system sport fisheries was eliminated in 1980 in response to escapement declines. Since 1986, improved escapements permitted the reopening of sport fisheries for chinook adults in a number of Fraser River locations. In 1989, chinook fisheries were opened in the Bowron, Clearwater, lower Fraser, Quesnel, lower Shuswap, South Thompson, Thompson and Vedder-Chilliwack rivers. The fisheries were regulated through harvest ceilings, time and area restrictions or daily and annual angler harvest limits. With the exception of the Bowron, Clearwater and Vedder-Chilliwack rivers, each fishery was evaluated using either a roving, access point or hybrid on-site survey.

A total of 4,044 anglers were interviewed in five study areas. An estimated 125,251 angler hours were expended to harvest an estimated 1,805 chinook adults, 159 chinook jacks, 8 sockeye salmon, 125 rainbow trout and 8 whitefish. Estimated releases totalled 159 chinook adults, 57 chinook jacks, 3 sockeye salmon and 3 rainbow trout. One hundred and one of the chinook adults were marked with adipose fin clips.

In an evaluation of angler response accuracy, the study concluded that anglers could accurately recall trip length but, when contacted during the trip, overestimated subsequent trip length by an average of one to three hours. The study also identified and discussed general biases associated with creel surveys.

Key words: upper Fraser River, sport fisheries, chinook salmon, angler effort, harvest, release, bias.

## RESUME

Schubert, N.D. 1992. Angler effort and catch in five Fraser River chinook salmon sport fisheries, 1989. Can. Manuscr. Rep. Fish. Aquat. Sci. 2128: 69p.

On a interrompu la pêche sportive des saumons quinnats (Oncorhynchus tshawytscha) adultes dans le bassin du fleuve Fraser en 1980 en raison du déclin de l'échappée. Depuis 1986, l'augmentation de l'échappée a permis la réouverture de la pêche sportive des quinnats adultes dans plusieurs régions de ce bassin. En 1989, on Ouvrait la pêche dans les rivières Bowron, Clearwater, Quesnel, South Thompson, Thompson, Vedder-Chilliwack et dans les cours inférieurs du Fraser et de la Shuswap. La pêche sportive y a été contrôlée par l'imposition de plafonds de prises, de restrictions temporelles et spatiales ou de limites quotidiennes et annuelles de prises. Sauf dans les rivieres Bowron, Clearwater et VedderChilliwack, chaque pêche a été évaluée au moyen d'une enquête menée de point d'accès à point d'accès ou hybride, sur le terrain.

En tout, 4044 pêcheurs sportifs ont été interrogés dans cing secteurs d'étude. Selon les estimations, 125251 heures-pêcheurs ont donné lieu à une récolte de 1805 quinnats adultes, 159 jeunes quinnats mâles, 8 saumons rouges, 125 truites arc-en-ciel et 8 corégones. On estime que 159 quinnats adultes, 57 jeunes quinnats mâles, 3 saumons rouges et 3 truites arc-en-ciel ont été relâchés. On a marqué 101 des quinnats adultes en coupant leur nageoire adipeuse.

L'évaluation de la précision des réponses des pêcheurs a montré que les pêcheurs dont le séjour de pêche est terminé ont un souvenir précis de sa durée, mais que ceux qui ont été interrogés durant leur séjour ont surévalué d'une à trois heures, en moyenne, le temps qu'ils pensaient encore passer à pêcher. par ailleurs, la présente étude traite des biais généraux qui se manifestent dans les enquêtes par interrogation des pêcheurs.

Mote-cles: partie supérieure du Fraser, pêches sportives, saumon quinnat, effort de pêche sportive, remise à l'eau, distorsion.

## INTRODUCTION

The escapement of chinook salmon (Oncorhynchus tshawytscha) to the Fraser River system improved since the early 1980's to an extent which permitted the reopening of sport fisheries in selected terminal areas (Schubert 1988, 1989, 1990). In 1989, sport fisheries were opened in the lower Fraser, Bowron, Clearwater, Quesnel, lower Shuswap, South Thompson, Thompson and VedderChilliwack rivers (Fig. 1). In most areas, structured assessment studies monitored fishery performance, evaluated stock impacts and provided data upon which future management decisions could be made.

This report describes the study design and field procedures and documents the results of the 1989 sport fishery assessment studies in the lower Fraser, upper Quesnel, lower Shuswap, South Thompson and Thompson rivers. The report presents estimates of angler effort, harvest and release by species, and angler attributes in each fishery, and concludes with a discussion of results and recommendations for the management and assessment of future fisheries.

## STUDY AREA DESCRIPTION

## FRASER RIVER

Sport fishing in the Fraser River occurs primarily from gravel bars in the lower 120 km below Agassiz (Fig. 2). In 1989, the retention of chinook adults was permitted throughout this area; however, the current study focused on a 28 km section between the Sumas River mouth and the Agassiz-Rosedale Bridge in June and July. Previous studies (DFO unpublished) had identified this as the major chinook interception area. Chinook adults from most Fraser River stocks were available to this fishery.

## QUESNEL RIVER

The Quesnel River originates in the Cariboo Mountains and flows in a northwesterly direction, entering the Fraser River at Quesnel (Fig. 3). Chinook sport fishing was permitted between the mouth and Beaver Creek ( 57 km ) and between Morehead Creek and the outlet of Quesnel Lake (25 km ). Only the latter area was assessed in 1989.

## SHUSWAP RIVER

The Shuswap River originates in the Monashee Mountains of southcentral British Columbia and flows in a northwesterly direction, entering Mara Lake east of Salmon Arm. Chinook sport fishing was permitted between Mara and Mabel lakes (Fig. 4). The open area was accessible by road and boat. Lower Shuswap River chinook salmon were the only stock available to the fishery.

## SOUTH THOMPSON RIVER

The South Thompson River originates at Little Shuswap Lake in south-central British Columbia and flows in a westerly direction for 65 km , entering the Thompson River at Kamloops (Fig. 1). Chinook sport fishing was permitted between the Pritchard and Chase bridges (Fig. 5). The open area was accessible by road and boat. The fishery was open during the peak migration of South Thompson River chinook; however, other South Thompson system chinook stocks may also have been available to the sport fishery.

## THOMPSON RIVER

The Thompson River arises at Kamloops Lake and flows in a southwesterly direction for 109 km , entering the Fraser River at Lytton (Fig. 1). Chinook sport fishing was permitted in 1 km section between the Highway 8 Bridge at Spences Bridge

[^0]and the upstream bank of the Nicola River, and in a 0.6 km section downstream from Martel. The open area was accessible by road on both sides of the river.

## FISHERY REGULATIONS

In general, the 1989 sport fisheries were managed through restrictions in fishing time, daily and annual angler harvest limits and fishery-specific harvest ceilings (Table 1). The main changes from 1988 (Schubert 1990) were: the lower Fraser River opened in June, the first time since 1979, and closed in late September to avoid harvest of Harrison River chinook; the lower Shuswap River opened one week earlier, an increase from 15 to 22 days; the South Thompson River opened earlier, an increase from 10 to 15 days; and the Thompson River fishery increased from 6 to 12 days and included a new area near Martel. Because the Thompson River harvest ceiling was reduced from 150 to 100 chinook adults, the fishing day was reduced by four hours (from 8 a.m. 8 p.m. to 6 a.m. - 2 p.m.) and the northwest side of the river near Spences Bridge was closed.

## METHODS

## STUDY DESIGN

## Fraser River

The lower Fraser River sport fishery between the Sumas River mouth and the Agassiz-Rosedale Bridge was assessed, using an access pointoverflight design (DPA Group MS 1985a), between June 3 and July 27, 1989. A single surveyor worked one of two eight-hour shifts ( $7 \mathrm{a} . \mathrm{m}$. to 3 p.m.; noon to 8 p.m.) which encompassed most daylight hours. The study period was stratified into weekday and weekend or holiday day types, with weekly assessment of three of the former and all of the
latter. In total, 39 of the 61 open days were assessed.

The surveyor was stationed at a landing ramp on the south shore of the Fraser River immediately across from Queen's Island, the area of maximum expected study area angler effort. Upon arrival on the morning shift, the surveyor crossed the river by boat to inquire if any anglers had left before $7 \mathrm{a} . \mathrm{m}$. and to request that anglers report for an interview at the end of their fishing trip. The surveyor then remained at the ramp to conduct hourly angler counts (using binoculars) and exit interviews. At the end of the shift, the surveyor again crossed the river by boat to interview any anglers still fishing. Each interview recorded angler trip length (to time of interview and expected additional time, if any), target species, number and species harvested or released, identifying marks on harvested fish (fin or maxillary clip), gear type and, if the angler had fished the lower Fraser River within two weeks, trip duration and harvest on the most recent trip. When possible, harvest was inspected to confirm species and mark identification. An interview form was completed for each angler; however, if the angler was unresponsive or if response reliability was questionable, the form was voided.

In addition to the above, the surveyor evaluated the angler's ability to recall trip duration at the end of the trip, and to predict subsequent duration when contacted during the trip. For the former, the estimated and actual trip durations were compared for anglers who completed an entire trip during the survey shift. For the latter, anglers already fishing were asked to estimate how much longer they intended to fish. If the angler completed the trip during the survey shift, the estimated and actual
subsequent trip durations were compared. In all cases, the surveyor ensured the angler was unaware that question response was being evaluated.

Approximately eight times per month, all anglers in the study area were counted from a Cessna 172 aircraft. Independent counts by two observers were made at noon and generally required 40 minutes.

## Quesnel River

The upper Quesnel River sport fishery was assessed, using a roving design, between August 5 and September 10, 1989. A single surveyor, working one of two nine-hour shifts (5 a.m. to 2 p.m.; 1 p.m. to 10 p.m.), surveyed all open days. The surveyor travelled a predetermined route by automobile, with a randomly selected start point and direction of travel. The surveyor's rate of travel through the fishery was standardized to ensure that a complete circuit encompassed seven hours. Anglers were approached on foot and interviewed as above. In addition to the interviews, the surveyor conducted two one-hour instantaneous rod counts of the entire study area at randomly selected times. No interviews were conducted during the rod count.

## Shuswap River

The Shuswap River sport fishery was assessed, using a hybrid design (Schubert 1988), between August 16 and September 4, 1989. Five surveyors worked one of two eight-hour shifts (5 a.m. to 1 p.m.: 1 p.m. to 9 p.m.). The study period was stratified into weekday and weekend or holiday day types, with weekly assessment of three of the former and all of the latter. In total, 16 of the 22 open days were assessed.

Surveyors were stationed at

Chuck's and Log Dump pools and Enderby and Grinrod bridges, the areas of maximum expected angler effort, while a roving surveyor assessed the remaining areas. Daily access point and roving survey procedures were identical to those described for the lower Fraser and Quesnel rivers, respectively, except instantaneous rod counts occurred during the two periods of expected daily effort maxima ( 6 a.m. to $7: 30$ a.m. on the morning shift; 6 p.m. to 7:30 p.m. on the afternoon shift) and the chinook harvest was sampled for size (nose-fork length and weight), flesh colour, sex, adipose fin status and scales.

## South Thompson River

The South Thompson River sport fishery was assessed, using a hybrid design, between August 30 and September 11, 1989. Two surveyors worked one of two eight-hour shifts (6 a.m. to 2 p.m.; noon to 8 p.m.). The study period was stratified into weekday and weekend or holiday day types, with weekly assessment of three of the former and all of the latter. In total, 10 of the 15 open days were assessed.

One surveyor was stationed at Banana Island, the area of maximum expected angler effort, while a roving surveyor assessed the remaining areas by boat. Daily access point and roving survey procedures were similar to those described for the lower Fraser and Quesnel rivers, respectively, except the instantaneous rod count occurred daily at 1 p.m. and angler response accuracy was not evaluated.

## Thompson River

The Thompson River sport fishery was assessed by complete census between July 8 and August 27, 1989. Surveyors worked a shift (initially 6 a.m. to 2 p.m., extended to 6 a.m. to

9 p.m. after July 30) encompassing the entire daily open period. Surveyors were stationed at the Nicola River mouth and immediately downstream from Martel. The former had several access points; however, because the entire open area was within sight of the surveyor, a secondary surveyor was able to contact other anglers before they left the river. Daily procedures were identical to those described for the lower Fraser River, except instantaneous rod counts were not required and the chinook harvest was sampled for size (nose-fork length and weight), flesh colour, sex, adipose fin status and scales.

## DATA MANAGEMENT

Data storage and analysis were conducted on an IBM AT compatible microcomputer. A custom designed data entry program (DPA Group Inc. MS 1985b) was used to generate ASCII files. The access point and hybrid survey files were then imported into a custom designed analysis program (DPA Group Inc. MS 1986), while the roving survey files were imported into a spreadsheet program for analysis.

The data were verified in three steps. First, all field data sheets were examined to ensure compliance with study procedures. Second, the data entry program performed 31 automatic error checks, including duplication detection, code validity, and range and consistency verification. Third, the ASCII data files were imported to a spreadsheet program for final verification with the field data sheets.

## DATA ANALYSIS

## Fraser River

Angler Effort: Profiles of daily angler effort were generated from hourly rod counts at Queen's

Island, with effort before 7 a.m. and after 8 p.m. reconstructed from interview data. Hourly effort was weighted to compensate for the sampling imbalance which resulted from overlapping survey shifts.

Mean sample day angler effort (hours) for each stratum was the ratio of the mean rod count from the overflights and the proportion of daily effort occurring during the rod count time block (noon to 12:40 p.m.). Total angler effort was the product of the mean daily angler effort and the number of days in the stratum. The mathematical relationships are reported below. Variance calculations are detailed in Appendix 20.

1) Estimated total rods fishing ( $\hat{R}_{h j}$ ), by hour and day type (weekday or weekend) :

$$
R_{h y}=\sum_{I} N_{h} / n_{h i j} \sum_{k} r_{h i j k}
$$

2) Estimated proportion of daily angler effort occurring during the instantaneous rod count time block ( $\bar{p}_{h j^{*}}$ ), by day type:

$$
\bar{P}_{h j^{*}}=\frac{\hat{R}_{h j^{*}}}{\sum_{\mathcal{J}} \hat{R}_{h j}}
$$

3) Estimated mean rod count during the instantaneous rod count time block ( $\bar{y}_{h j^{*}}$ ), by day type:

$$
\bar{y}_{h y^{*}}=\sum_{k} \frac{y_{h y^{*} k}}{n_{h j^{*}}}
$$

4) Estimated angler effort ( $E_{h}$ ), by day type, in hours:

$$
E_{h}=N_{h} \frac{\bar{y}_{h j^{*}}}{\bar{p}_{h j^{*}}}
$$

5) Estimated study period angler effort ( $E$ ), in hours:

$$
E=\sum_{h} E_{h}
$$

where:

Catch Per Unit Effort: CPUE was calculated by species and mark group using a total ratio estimator (Von Geldern, Jr. and Thomlinson 1973; Malvestuto 1983), i.e. the total estimated catch was divided by the total estimated effort (to time of interview). Estimates were derived from interview data weighted by the proportion of study period stints which were surveyed (the day was divided into three stints: 7 a.m. to noon; noon to 3 p.m.; and 3 p.m. to 8 p.m.) to account for sampling imbalances resulting from overlapping survey shifts and the proportion of anglers in each hour who left the site without an interview. CPUE was calculated separately for harvested (HPUE) and released (RPUE) fish; however, RPUE was not calculated by mark type because angler mark recognition was considered unreliable. The mathematical relationships are reported below.
6) Estimated study period catch to
time of interview at the survey site $\left(\hat{X}_{h}\right)$, by day type:

$$
\hat{x}_{h}=\sum_{1} \sum_{I} \frac{1}{a_{h 11}} \sum_{I} \sum_{q} \sum_{u} \frac{x_{h+1 f q u}}{a_{h+1 f q}}
$$

7) Estimated study period angler hours to time of interview at the survey site $\left(\hat{f}_{h}\right)$, by day type:

$$
\mathrm{f}_{b}=\sum_{1} \sum_{I} \frac{1}{a_{h 11}} \sum_{\Gamma} \sum_{q} \sum_{u} \frac{t_{h 11 f q u}}{a_{h 11 f q}}
$$

8) Estimated catch per angler hour at the survey site $\left(\bar{c}_{h}\right)$, by day type:

$$
\bar{c}_{h}=\frac{\hat{X}_{h}}{\hat{T}_{h}}
$$

where:

Before calculating CPUE, the raw interview data were tested for significant differences in CPUE between all interviews and complete trip interviews. The test used, from Cochran (1977), was:
9) Estimated variance of the

$$
\begin{aligned}
& \text { difference between two ratios } \\
& \left(\operatorname{Var}\left(\bar{c}_{c}-\bar{c}_{t}\right):\right. \\
& \operatorname{Var}\left(\bar{c}_{c}-\bar{c}_{t}\right)=\operatorname{Var}\left(\bar{c}_{c}\right)+\operatorname{Var}\left(\bar{c}_{t}\right)
\end{aligned}
$$

where:

Harvest and Release: Total harvest and release, estimated by species and mark group, was the sum of individual estimates for the weekday and weekend or holiday strata. For each stratum, harvest and release was the product of stratum effort and the corresponding value of HPUE or RPUE.
10) Total study period catch (C):

$$
C=\sum_{h} \bar{c}_{h} E_{h}
$$

Harvest Rate: In all study areas, the harvest rate of chinook adults was the ratio of the estimated harvest and the sum of the estimated harvest and the observed escapement (provided by field staff). Harvest rates were not calculated for other species because total abundance was unknown.

Angler Characteristics: In all study areas, the following unweighed angler attributes were summarized by
site and day: mean angler day length by weather type (clear, overcast and rain), mean angler day length from complete and incomplete trip interviews, numbers of anglers fishing for each species and preferred gear type. Study period mean angler day length, calculated from complete trip interviews, was estimated from sitespecific data weighted by estimated angler effort. Results of the angler response verification were summarized by study period.

## Queanel River

Angler Effort: A profile of hourly angler effort was generated from the twice daily study area rod counts. Mean daily angler effort was the sum of the mean rod count in each two-hour time block. Total angler effort was the product of the mean daily angler effort and the number of days in the study period. The mathematical relationships are described below; variance was calculated using standard procedures.
11) Estimated mean rod count during the two-hour time block $j\left(\bar{y}_{j}\right)$ :

$$
\bar{y}_{j}=\frac{\sum_{k} 2 r_{j k}}{n_{j}}
$$

12) Estimated mean daily angler effort ( $\bar{E}$ ), in hours:

$$
\bar{E}=\sum_{\mathcal{J}} \bar{y}_{\boldsymbol{y}}
$$

13) Estimated study period angler effort ( $E$ ), in hours:

$$
E=N \bar{E}
$$

Catch par Unit effort: CPUE was calculated by species and mark group for each stratum using a total ratio estimator. In general, CPUE was estimated as described for the
lower Fraser River, except observed catch and effort to time of interview were used, and the data were not weighted by the proportion of anglers leaving without being interviewed. CPUEs and their variances were calculated as follows:
14) Catch per unit effort ( $\bar{C}$ :

$$
\bar{c}=\sum_{I} \frac{w_{1}\left(\sum_{u} x_{u} / \sum_{u} t_{u}\right)}{\sum_{I} w_{1}}
$$

15) Variance of CPUE (Var $(\bar{c}))$

$$
\operatorname{Var}(\bar{c})=\left(1 / \bar{t}^{2}\right) \sqrt{\frac{\sum_{u}\left(\left(x_{u}-\bar{c}\right) t_{u}\right)^{2}}{n(n-1)}}
$$

where:

$$
\begin{aligned}
x_{u} & =\begin{array}{l}
\text { catch to time of inter- } \\
\text { view of angler u; } \\
t_{u}
\end{array} \quad=\begin{array}{l}
\text { hours fished to time of } \\
\text { interview by angler } u ; \\
\text { mean time spent angling }
\end{array} \\
\bar{t} & =\begin{array}{l}
\text { to time of interview; }
\end{array} \\
n & =\begin{array}{l}
\text { number of anglers inter- } \\
\text { viewed in stratum; }
\end{array} \\
w_{1}= & \begin{array}{l}
\text { proportion of stints of } \\
\text { type } 1 \text { which were surve- } \\
\text { yed. }
\end{array}
\end{aligned}
$$

Harvest and Release: Total harvest and release, by species and mark group, was calculated as in Equation 10.

## Shuswap River

Lower Shuswap River data were analyzed using the procedure described for the lower Fraser River. Angler effort was calculated from profiles observed at Chuck's and Log Dump pools and Enderby and Grinrod bridges, and from instantaneous counts from the above sites and the roving survey. CPUE was generated
from information collected at all sites; however, CPUE was first tested for differences between sites in addition to between interview types (Equation 9). If a significant difference in CPUE was noted between sites, then equations 6,7 and 8 were replaced with the following:
16) Estimated total catch to time of interview $\left(\hat{X}_{h 1}\right)$, by site and day type:

$$
\hat{X}_{h i}=\sum_{I} \frac{1}{a_{h 11}} \sum_{f} \sum_{g} \sum_{u} \frac{x_{h i l f q u}}{a_{h+1 f g}}
$$

17) Estimated total angler hours to time of interview $\left(f_{h 1}\right)$, by site and day type:

$$
f_{h i}=\sum_{I} \frac{1}{a_{h i 1}} \sum_{f} \sum_{q} \sum_{u} \frac{t_{h i 1 f{ }^{2}}}{a_{h i 1 f q}}
$$

18) Estimated catch per angler hour $\left(\bar{c}_{h 1}\right)$, by site and day type:

$$
\bar{c}_{h i}=\frac{\hat{X}_{h i}}{\hat{P}_{h 1}}
$$

Estimated mean catch per angler hour at all sites (weighted by site angler effort) ( $\bar{C}_{h}$ ), by day type:

$$
\bar{c}_{h}=\frac{\sum_{i} \bar{c}_{h i} E_{h i}}{\sum_{1} E_{h i}}
$$

where:

$$
\begin{aligned}
& E_{h i x}=N \frac{\bar{y}_{h i j^{*}}}{\bar{P}_{h j^{*}}} \\
& =\text { estimated total angler } \\
& \text { effort at site } i \text { on day } \\
& \text { type } h \text {; } \\
& \bar{Y}_{h 1 j^{*}}=\text { mean rod count at site } i \\
& \text { on day type } h \text { during the } \\
& \text { instantaneous rod count } \\
& \text { time block. }
\end{aligned}
$$

## South Thompson River

South Thompson River data were analyzed using the procedures described for the lower Fraser and Shuswap rivers. Angler effort was calculated from the 1987 profile (Schubert 1989) and from instantaneous counts from the roving and Banana Island surveys. CPUE was generated from information collected at Banana Island and by the roving survey.

## Thompson River

Because the Thompson River study was a complete census, angler effort, CPUE and catch were measured directly: angler effort was the sum of the hours fished by all anglers; catch was the sum of the observed catch to time of interview; and CPUE was the ratio of catch and angler effort. The mathematical relationships are reported below.
20) Total angler effort (E), in hours:

$$
E=\sum_{I} \sum_{u} t_{i u}
$$

21) Total study period catch (C):

$$
C=\sum_{i} \sum_{u} x_{i u}
$$

22) Total catch per angler hour ( $\bar{C}$ )

$$
\bar{C}=\frac{C}{E}
$$

## RESULTS

Study results for the five Fraser River chinook sport fisheries are summarized in Tables 2,3 and 4. Based on 4,044 interviews, an estimated 125,251 angler hours (24,949
angler days) were expended to harvest (release) 1,805 (159) chinook adu1ts, 159 (57) chinook jacks, 8 (3) sockeye (Oncorhynchus nerka), 125 (3) rainbow trout (Oncorhynchus mykiss) and 8 whitefish (Prosopium sp.). Chinook adult harvest rates ranged from $1.08 \%$ to $2.52 \%$.

The 1989 fisheries were successful in attracting anglers primarily interested in harvesting chinook salmon; the proportion of lower Fraser River anglers fishing for anything probably reflects interviewer error. The average angler fished for 2.0 to 7.0 hours per day using bait, lures or a combination of the two; few fished with flies. The average angler expended 11 to 162 hours to harvest one chinook adult. Results by study area are detailed below.

## FRASER RIVER

## Effort Distribution

One thousand, eight hundred and fifty-five anglers were interviewed at Queen's Island during the two month study period, 810 in June and 1,045 in July (Appendix 1). Weekday and weekend rod counts averaged 54 and 132 , respectively, in June and 115 and 284 , respectively, in July (Appendix 2). In June, $59 \%$ and $52 \%$ of the weekday and weekend anglers, respectively, were observed on Queen's Island, declining to $41 \%$ and 38\%, respectively, in July.

## Angler Effort

Daily Profile: Anglers fished from 1 a.m. to 10 p.m., with $80 \%$ of the effort occurring between 9 a.m. and 9 p.m. (Appendix 3; Fig. 6). Angler effort was relatively static between $10 \mathrm{a} . \mathrm{m}$. and $6 \mathrm{p} . \mathrm{m}$.

Total Angler Effort: Study period angler effort totalled 90,678

Table 2. Harvest, release and angler effort in the 1989 Fraser River study areas ( $95 \%$ confidence limits in parentheses).

Figure 6 Hourly Angler Effort Protiles in the 1989 Study Area Spont Fisheries.
hours or 14,143 days (Table 2). Fifty-five percent of the angler effort occurred on weekend or holiday days, and 44\% occurred on Queen's Island.

## Catch Per Unit Effort

Harvest: Weighted chinook adult HPUE, expressed as fish per hour, was estimated at 0.0229 in June and 0.0106 in July (Appendix 4). HPUE was highest from late June through mid July. No significant difference ( $p<0.05$ ) was noted in HPUE estimated from complete trip and all interviews (Table 5), nor was a consistent difference noted between weekday and weekend HPUE.

Release: Weighted chinook adult RPUE was estimated at 0.0028 in June and 0.0007 in July (Appendix 4).

## Harvest

Harvest was estimated at 1,282 chinook adults and 76 chinook jacks (Table 2). Forty-seven percent of the chinook adult harvest occurred in June, with the remainder in July. Seventy-two of the chinook adults had an adipose fin clip, with 11 (15.3\%) coded wire tags recovered from mainly Thompson system stocks: Nicola (3), Coldwater (1), Deadman (1), Bonaparte (1), middle Shuswap (2), Salmon (1), Raft (1) and Chilliwack (1).

## Release

An estimated 116 chinook adults, 11 chinook jacks and 3 sockeye were intentionally released in 1989 (Table 2).

## Angler Characteristics

Angler day Length: Anglers fished and average 7.0 and 6.2 hours per trip in June and July, respectively (Table 3). Angler day length averaged $6.9,6.9$ and 7.3 hours on clear, overcast and rainy days, res-
pectively.
Target speciea: Anglers expressed no species preference in 1989 (Table 3); however, because chinook were the dominant harvestable species, it is likely that most were fishing for chinook.

Gear Type: All anglers used lures in 1989 (Table 3).

Previous Trip: In June and July, $54.6 \%$ and $75.0 \%$, respectively, of the anglers interviewed had fished for chinook in the lower Fraser River within the last two weeks (Appendix 1). Unweighed chinook adult HPUE on the most recent trip was 0.0307 and 0.0173 in June and July, respectively (Table 5).

Angler Response Verification: Accuracy in recalling trip length was evaluated for 40 anglers (Appendix 5). Recall error ranged from under and over estimates of up to one and three hours, respectively; however, $93 \%$ of the anglers estimated trip length to within one hour, with a mean error of +0.2 hours.

Accuracy in projecting subsequent trip length when contacted during the trip was evaluated for 40 anglers (Appendix 5). Error ranged from under and over estimates of up to 2 and 12 hours, respectively. Only $30 \%$ of the anglers predicted subsequent trip length within one hour, and the distribution of responses was skewed with a mean error of +3.2 hours.

## QUESNEL RIVER

## Effort Digtribution

One hundred and twenty-six anglers were interviewed during the 12 day study period (Appendix 6). Two instantaneous rod counts were conducted at random times each open
day (Appendix 7). Angling occurred primarily at road access points, with most anglers observed near the Quesnel Lake outlet (the Narrows) (29\%) and downstream from Likely (66\%). Few (5\%) were observed between Likely and the Narrows.

## Angler Effort

Daily Profile: Anglers fished from before 7 a.m. to 9 p.m., with $80 \%$ of the effort occurring from 10 a.m. to 7 p.m. (Appendix 3; Fig. 6). Effort peaked at 3 p.m.

Total Angler Effort: Study period angler effort totalled 1,832 hours or 916 days (Table 2).

## Catch Per Unit Effort

Harvest: Chinook adult HPUE was estimated at 0.0218 , with most of the harvest occurring on the last weekend (Appendix 8). No significant difference ( $p<0.05$ ) was noted in HPUE estimated from complete trip and all interviews (Table 5), probably reflecting the small sample size of the former.

Release: No fish of any species were released in 1989.

## Harvest

Harvest was estimated at 40 chinook adults, 8 sockeye, 79 rainbow trout and 8 whitefish (Table 2).

## Release

No fish were release in 1989.

## Angler Characteristics

Angler Day Length: Anglers fished an average 2.0 hours per trip (Table 3). Angler day length averaged 1.7 and 2.0 hours on clear and overcast days, respectively. There were was no rain during the 1989 study period.

Target species: Anglers attempted to harvest chinook (57\%), trout (38\%) or anything (5\%) (Table 3).

Gear Type: Bait/Lure combinations were the most commonly used gear (44\%), followed by lures (29\%), bait (18\%) and flies (10\%) (Table 3).

Previoue Trip: Twenty percent of the anglers interviewed had fished for chinook in the Quesnel River within the last two weeks (Appendix 6). Chinook adult HPUE on the most recent trip was 0.0265 (Table 5).

## SHOSWAP RIVER

## Effort Distribution

One thousand, one hundred and thirty-six anglers were interviewed during the 22 day study period (Table 2), 336 at Chuck's Pool, 183 at Log Dump Pool, 247 at Enderby Bridge, 97 at Grinrod Bridge and 273 in the remaining areas (Appendix 9).

Weekday rod counts averaged 55 and 73 in the morning and evening, respectively, while weekend rod counts averaged 66 and 83 , respectively (Appendix 10). Angling occurred near road access points throughout the lower Shuswap River. On weekdays and weekends, respectively, $27 \%$ and $36 \%$ of the anglers were observed between Mable Lake and skookumchuck, $23 \%$ and $20 \%$ between Fall and Cooke creeks and $15 \%$ and $12 \%$ between Grinrod and Enderby bridges. Few (less than 3\%) were observed between Cooke Creek and Skookumchuck (Appendix 10).

## Angler Effort

Daily Profile: Anglers fished the lower Shuswap River 24 hours per day (Appendix 3; Fig. 6). Effort was bimodal, with peaks at 7 a.m. and 7 p.m. on weekdays and 7 a.m. and 8 p.m. on weekends.

Total Angler Effort: Study period angler effort totalled 19,449 hours or 6,483 days (Table 2). Fifteen percent of the effort occurred at Chuck's Pool, 10\% at Log Dump Pool, $15 \%$ at Enderby Bridge, $8 \%$ at Grinrod Bridge and $51 \%$ in the remaining areas.

## Catch Per Unit Effort

Harvest: Weighted chinook adult HPUE was estimated at 0.0062 . No significant difference ( $\mathrm{p}<0.05$ ) was noted in HPUE estimated from complete trip and all interviews (Table 5); however, a significant difference ( $\mathrm{p}>0.05$ ) was noted between sites. Chinook adult HPUE ranged from 0.0012 at Enderby Bridge to 0.0186 at Chuck's Pool (Appendix 11).

Release: Weighted chinook jack RPUE was estimated at 0.0007 .

## Harvest

Harvest was estimated at 120 chinook adults, 40 chinook jacks and 45 rainbow trout (Table 2). Ten of the chinook adults had an adipose fin clip, with coded wire tags recovered from 2 (20.0\%) heads. Both were lower Shuswap River chinook.

Harvest Sampling: Sample results from the 1989 lower Shuswap River sport fishery are detailed in Appendix 12. The sample consisted entirely of red fleshed chinook, with males comprising $40 \%$ of the total. Overall size averaged 73.2 cm nosefork length and 6.2 kg round weight. The harvest consisted of ages $5_{1}$ (24\%) , $4_{2}$ (12\%), $4_{1}$ (24\%), $3_{1}$ (18\%) and $2_{1}$ (24\%).

## Release

Release was estimated at 13 chinook jacks (Table 2).

## Angler Characteristics

Angler Day Length: Anglers fished an average 3.0 hours per trip (Table 3). Angler day length averaged 3.5, 3.4 and 3.6 hours on clear, overcast and rainy days, respectively.

Target Species: Anglers attempted to harvest chinook (97\%), trout (2\%) or anything (1\%) (Table 3).

Gear Type: Lures (71\%) were the most commonly used gear, followed by bait/lure combinations (15\%), bait (14\%) and flies (1\%) (Table 3).

Previous Trip: Fifty-six percent of the anglers interviewed had fished for chinook in the lower Shuswap River within the last two weeks (Appendix 9). Chinook adult HPUE on the most recent trip averaged 0.0082 (Table 5).

Angler Responge Verification: Accuracy in recalling trip length was evaluated for 81 anglers (Appendix 5). Recall error ranged from under and over estimates of up to four and two hours, respectively; however, $83 \%$ of the anglers estimated trip length to within one hour of the correct time, and the mean error was 0.0 hours.

Accuracy in projecting subsequent trip length when contacted during the fishing trip was evaluated for 51 anglers (Appendix 5). Error ranged from under and over estimates of up to 1 and 15 hour, respectively. Although $73 \%$ of the anglers predicted trip length to within one hour of the actual time, the distribution of responses was skewed with a mean error of +0.8 hours.

## SOUTH THOMPSON RIVER

## gffort Digtribution

Five hundred and eighty-one
anglers were interviewed during the 15 day study period (Table 2), 76 at Banana Island and 505 in the remaining areas (Appendix 13).

Weekday and weekend rod counts averaged 39 and 65, respectively (Appendix 14). Angling occurred throughout the study area, with a significant number of anglers accessing the fishery by boat. On weekdays and weekends, respectively, $47 \%$ and $37 \%$ of the anglers were observed in the area near Banana Island, $31 \%$ and $36 \%$ near Prichard, and $19 \%$ and $22 \%$ near Chase.

## Angler Effort

Daily Profile: Because of surveyor unreliability, the hourly angler effort profile was not evaluated in 1989. The 1987 effort profile was used in the analysis (Schubert 1989).

Total Angler Effort: Study period angler effort totalled 12,118 hours or 3,107 days (Table 2).

Catch per Unit Effort
Harvest: Weighted chinook adult HPUE was estimated at 0.0214; HPUE was similar between sites (Appendix 15). No significant difference ( $\mathrm{p}<0.05$ ) was noted in HPUE estimated from complete trip and all interview (Table 5)

Release: Weighted chinook adult RPUE was estimated at 0.0002 .

## Harvest

Harvest was estimated at 259 chinook adults and 42 chinook jacks (Table 2).

## Release

Release was estimated at 3 chinook adults and 33 chinook jacks (Table 2).

## Angler Characteristica

Angler Day Length: Anglers fished an average 4.4 hours per day (Table 3). Angler day length averagged $3.1,4.2$ and 3.0 hours on clear, overcast and rainy days, respectively.

Target Species: Anglers attempted to harvest chinook (99\%), trout (less than 18 ) or anything (less than 18) (Table 3).

Gear Type: Lures were the most commonly used gear ( $90 \%$ ), followed by bait/lure combinations (78) and bait (3\%) (Table 3).

Previous Trip: Previous trip information was not collected in 1989 due to surveyor error.

## THOMPSON RIVER

## Effort Distribution

Three hundred and forty-six anglers were interviewed during the 12 day study period (Table 2), 295 near the Nicola River mouth and 51 at Martel (Appendix 16). Effort was censused, with complete angler counts each hour.

## Angler Effort

Daily Profile: The 1989 fishery was open from 6 a.m. to 2 p.m. during July $8-30$ and from 6 a.m. to 9 p.m. during August 6-27. Angler effort peaked at 8 a.m. (Appendix 3; Fig. 6).

Total Angler Effort: Study period angler effort totalled 1,174 hours or 301 days (Table 2). Ninetytwo percent of the effort (1,079 angler hours) occurred near the Nicola River mouth.

## Catch Per Unit Effort

Harvest: Chinook adult HPUE
was 0.0964 at the Nicola river mouth and 0.0000 at Martel (Appendix 17).

Release: Chinook adult RPUE was 0.0371 at the Nicola River mouth and 0.0000 at Martel (Appendix 17).

## Harvest

Harvest totalled 104 chinook adults (19 without an adipose fin), 1 chinook jack and 1 rainbow trout (Table 2). All of the chinook were harvested at the Nicola River mouth; 1 rainbow trout was harvested at Martel.

Harvest Sampling: Sample results from the 1989 Thompson river sport fishery are detailed in Appendix 18. The harvest, which consisted entirely of red fleshed chinook, consisted $62.5 \%$ of males and $37.5 \%$ females. Overall size averaged 74.4 cm nose-fork length and 4.6 kg . The harvest consisted of ages $5_{2}$ (11\%), $\mathbf{4}_{2}$ ( $83 \%$ ), $4_{1}$ (2\%) and $3_{1}$ (5\%). All of the 19 chinook without adipose fins had CWTs; 18 were Spius Creek Hatchery releases of Nicola River chinook and 1 was a 1986 brood Deadman River chinook.

## Release

Release totalled 40 chinook adults and 3 rainbow trout (Table 2).

## Angler Characteristica

Angler Day Length: Anglers fished and average 3.9 hours per trip (Table 3). Angler day length averaged 3.9 and 4.3 hours on clear and overcast days, respectively. There were no rainy days during the 1989 study period.

Target Speciea: Anglers attempted to harvest chinook (95\%), trout (3\%) or anything (2\%).

Gear Type: Bait was the most commonly used gear (76\%), followed by
bait/lure combinations (14\%), lures (8\%) and flies (2\%) (Table 3).

Previous Trip: Previous trip information was not collected in 1989 due to surveyor error.

## DISCUSSION

## GENERAL

Fraser River
The lower Fraser River fishery was the largest of those surveyed, with over $70 \%$ of the angler effort and chinook adult harvest (Table 4). Fishery dynamics reflected chinook abundance, which peaked in late June (DFO unpublished), and Fraser River flows, which declined through the study period. Initial angler effort was low and occurred primarily on Queen's Island, one of the few high water angling sites. Subsequent effort increased with increasing chinook abundance and HPUE (Appendix 4) and dispersed to new sites as they emerged from the water; the proportion of total effort which occurred on Queen's Island declined from $60 \%$ in early June to $36 \%$ in late July (Appendix 2). After early July, declining chinook abundance had two effects: reduced total effort (Appendix 2) and a more pronounced effort dispersion due to reduced HPUE on Queen's Island (Appendix 4).

An assumption underlying the study methodology was that either the interview site was representative of the study area or the proportion of effort occurring at the site was sufficient to make the HPUE estimate insensitive to differences in other areas. In June, over $50 \%$ of the study area angler effort occurred at the survey site; therefore, the HPUE estimate was likely insensitive to differences in other areas. With effort dispersion in July, however, violation of the assumption of

Table 4. Harvest rate, catchability and harvest per unit effort (HPUE) in the 1989 Fraser River study areas. a

a. 1986-88 Quesnel, Shuswap, South Thompson and Thompson data from Schubert (1988, 1989, 1990).
b. 1986-88 effort and harvest estimated using 1989 procedures and unpublished data; catchability coefficient and harvest rate could not be calculated because stock-specific timing at the fishery site was not known.
c. First year of chinook adult retention since 1980.
d. Assumes fishery harvest was entirely from main Thompson River stocks, i.e. of Bonaparte, Deadman and Nicola chinook.
representativeness became more important. In July 1988, HPUE was estimated at three study area sites, Queen's Island, Wing Dam and Englebrich bars (DFO unpublished). Although between site differences were noted, only Wing Dam Bar was significantly different ( $\mathrm{p}<0.05$ ). While study area HPUE was not homogeneous, effort at Wing Dam Bar was low in both years. The potential impact on study results, therefore, may have been minor.

The June chinook adult sport fishery in the lower Fraser River was reopened in 1989 for the first time since 1980. June angler effort increased over sevenfold relative to 1988 (Table 4), with mean angler counts increasing from 8 to 54 on weekdays and from 20 to 132 on weekends. In contrast, angler effort in the July fishery, where chinook retention has been permitted since 1987, remained relatively static over the same years but increased almost fourfold in 1987. Retention of chinook salmon, therefore, was a major determinate in the decision to participate in this fishery. Evaluations of future regulations should anticipate such responses.

## Quennel River

The 1989 upper Quesnel River sport fishery attracted minimal angler effort and harvested few chinook adults (Table 4). While chinook adult harvest, catchability, harvest rate and HPUE increased in 1989, the fishery remained a minor one. Further intensive monitoring is not warranted unless the fishery expands.

Evaluation of the upper Quesnel fishery was difficult due to the low effort and the short fishing period of 12 days. In 1989, only 126 angler interviews were collected, of which 27 were complete trip interviews. In testing for incomplete trip interview bias, sample size influenced the con-
clusion that no difference existed between the two interview types despite a large difference in HPUE (Table 5). Error in this conclusion would result in an underestimate of harvest.

## Shuswap River

The lower Shuswap River fishery was one of the most intensive in the upper Fraser River system, with considerably greater angler effort than the Quesnel River, South Thompson River and Thompson River fisheries (Table 4). Effort increased by $36 \%$ over 1988 due to an increase in days open from 15 to 22; however, mean daily angler effort actually declined by 7\%. Chinook adult catchability was similar to 1988 and below the 1986-87 level (Table 4). The 1988 decline was coincident with a change in fishing time from 2 to 7 days per week. It was hypothesized that, after exposure to angling, Shuswap River chinook exhibited a refractory period in which they were relatively unresponsive to angling. The expansion of the fishery from 2 to 7 days per week would have reduced catchability by eliminating the recovery period. If this was the case, catchability would be higher in the more remote, less crowded areas. In 1989, effort was more dispersed as anglers apparently searched for more effective fishing sites. For example, the proportion of annual angler effort at the two largest sites (Chuck's and Log Dump pools) declined from $68 \%$ in 1988 (Schubert 1990) to 258 in 1989. While angler behavior may be evolving in this fishery, the study was designed to contact all but a very small proportion of the anglers. These changes, therefore, were unlikely to have biased study results.

## South Thompson River

The South Thompson River fishery expanded from 1987, the last year it was assessed (Table 4). Angler
effort doubled, chinook adult harvest increased eightfold and HPUE increased almost fourfold. These results, however, should be interpreted with caution. The 1989 study was unable to estimate the daily angler effort profile and, instead, used one generated in 1987. Error in the assumption that profiles were similar could generate considerable error in the estimate. For example, assessment data from the 1986-89 lower Shuswap River fishery (Schubert 1988, 1989, 1990) show up to a fourfold error in the effort estimate had the profile from a single year been used. While the South Thompson River estimates should be interpreted with caution, two factors suggest that harvest was considerably higher in 1989. First, daily rod counts recorded in the same time blocks were similar in 1987 and 1989. Because the fishery expanded from 5 days in 1987 to 15 days in 1989, total angler effort was almost certainly higher in 1989. Second, HPUE increased over threefold in 1989. While the the 1989 estimates of harvest and effort are not known with certainty, both effort and harvest increased substantially since 1987.

## Thompson River

The Thompson River (Spences Bridge) fishery was an effective harvestor of chinook salmon, with one of the highest harvest rates and by far the highest HPUE and catchability coefficient in 1989 (Table 4). An average of only 11 hours was required to harvest one chinook adult.

In calculating the 1989 fishery harvest rate, two assumptions were made: first, that passing chinook from North and South Thompson River stocks were not vulnerable; and second, that Thompson River stocks (Bonaparte, Deadman and Nicola) were equally vulnerable. The 1988 study concluded that the first assumption was reasonable because: a) all CWTs
recovered in the fishery were from main Thompson River stocks; b) fish size and age were consistent with main Thompson stocks; and c) timing in the lower Fraser River was consistent with a stock which would be differentially vulnerable while holding in the Thompson River near the tributary of origin (Schubert 1990). The second assumption, however, may be invalid. Harvest rate calculated from the Nicola River CWTs observed in the catch (18) and estimated in the escapement (778; C. Cross, pers. comm.) was $2.3 \%$, higher than the $2.0 \%$ estimated in this study. Further, based on the estimated proportion of the Nicola River stock which returned with CWTs, an estimated $88 \%$ of the catch was of Nicola River origin, while Nicola River chinook comprised only $73 \%$ of the main Thompson River chinook escapement. It was concluded, therefore, that Nicola River chinook were differentially vulnerable to this fishery.

The 1989 sport fishery was further restricted from 1988 due to the decline of Nicola River Chinook escapements. The 1989 regulations were relatively successful in constraining the fishery within the 100 harvest ceiling due primarily to the inseason catch monitoring program which provided a complete census of the fishery. The status of this stock, however, remains a concern. Although the 1989 escapement increased, it was below the brood year level and, without enhancement, the declining trend which began in 1986 would not have been halted. Given the effectiveness of this fishery, restrictive management should continue until the stock shows a clear rebuilding trend.

## INCOMPLETE TRIP INTERVIEN BIAS

[^3]Table 5. Estimated chinook adult harvest per unit effort (HPUE), by interview type, in the 1989 Fraser River study areas.

|  | Interview <br> type | Number <br> of <br> interviews | Angler <br> hours | Chinook <br> adult <br> harvest | Chinook <br> adult <br> HPUE |
| :--- | :--- | ---: | ---: | ---: | ---: |
| Location |  | 339 | 2,382 | 56 | 0.0235 |
| Lower Fraser | Complete trip | 810 | 5,690 | 128 | 0.0225 |
| River, June | Combined | Previous Trip | 442 | 3,162 | 97 |

[^4]incomplete trip interviews, i.e. interviews from anglers contacted during their trip (Schubert 1989). In 1988-89, this bias was addressed by increasing the maximum daily angler harvest limit from one to two chinook adults per day (Schubert 1990). In both years, no significant difference ( $p>0.05$ ) was noted in complete versus combined trip interview HPUE (Table 5), suggesting the change corrected this bias. Other indicators support this conclusion in certain 1989 study areas. HPUE was clearly independent of trip length (Fig. 7) in the Quesnel, lower Shuswap and South Thompson fisheries, and

HPUE generated from angler estimates of harvest and angling time on their most recent trip were more similar to those generated from combined interviews in the Shuswap and Quesnel River fisheries (Table 5).

## ANGLER RESPONSE VERIFICATION

The ability of anglers to recall trip length and to predict subsequent trip length was evaluated in the lower Fraser River and lower Shuswap River sport fisheries. The studies had similar results and will be pooled for the purpose of this discussion.

Figure 7 Harvest Per Unit Effort of Chinook Adults, by Angler Trip Duration, the 1989 Study Area Sport Fisheries.

Figure 7 cont'd. Harvest Per Unit Effort of Chinook Adults, by Angler Trip Duration, in the 1989 Study Area Sport Fisheries.

Figure 8 Angler Recall of Trip Duration at Trip's End and
Prediction of Subsequent Trip Duration During the Trip.

Anglers were able to accurately recall trip length. For example, the average and maximum deviation between estimated and actual trip length was +0.1 and -4 hours, respectively, with $86 \%$ of the estimates within one hour of the true trip length (Fig. 8; Appendix 5). In contrast, anglers estimated subsequent trip length with both bias and error. The average and maximum deviation between the estimated and actual subsequent fishing time was +2 and +15 hours, respectively, with only $56 \%$ of the estimates within one hour of the true fishing time (Fig. 8; Appendix 5). Inaccuracy likely reflects a variety of factors, such as post-interview changes in weather, angling success, hunger, etc. which would affect an angler's decision to continue fishing. In contrast, the ability to recall trip length is constrained only by short term memory.

## RECOMMENDATIONS

1. The 1989 sport fishery regulations were successful in constraining harvest to ceiling levels. Contingent upon stock strength, regulations could be further relaxed in the Quesnel and lower Shuswap fisheries. Changes cannot be recommended for the South Thompson River fishery until problems encountered in study implementation are corrected.
2. The Thompson River (Spences Bridge) sport fishery was an extremely effective harvester of chinook salmon. Because this fishery harvests primarily Nicola River chinook salmon, restrictive regulations should continue until the decline of Nicola River chinook escapements is halted and a rebuilding trend is established.
3. Structured fishery assessment
studies should occur in the following areas: lower Fraser and lower Shuswap rivers, due to the high effort and chinook harvest levels; South Thompson River, to provide a proper evaluation of a fishery which has apparently expanded substantially since it was opened in 1986; and Thompson River, an effective fishery which targets on a stock of concern. Further evaluation is also required on the Clearwater River, which has not been monitored since 1986. Further monitoring is not required on the Quesnel River.

## SUMMARY

1. Sport fishery assessment studies were conducted in the lower Fraser, upper Quesnel, lower Shuswap, South Thompson and Thompson (Spences Bridge) rivers in 1989. In general, each fishery was managed through restrictions in fishing time, daily and annual angler harvest limits and fishery-specific harvest ceilings. Each fishery was managed in a manner similar to the previous year, except the number of days open increased in the Shuswap (from 15 to 22 days), South Thompson (from 10 to 15 days) and Thompson (from 6 to 12 days) rivers. The lower Fraser River fishery opened on June 1 , one month earlier than in 1988. The Thompson River harvest ceiling was reduced from 150 to 100 chinook adults.
2. The fisheries were assessed using a complete census (Thompson River), roving (upper Quesnel River), hybrid (lower Shuswap and South Thompson) or access point-overflight (lower Fraser River) survey.
3. Each fishery was assessed by one to five surveyors, depending on the extent of the open area, expected angler effort and available resources. The surveyors recorded the following information during 4,044 angler interviews: length of time angling, preferred species, number and species of fish harvested or released, identifying marks on harvested fish and gear type. In addition, if the angler had fished the river in the last two weeks, the interviewer recorded the number of previous trips in 1989 and, on the most recent trip, the harvest and length of time angling. In the lower Shuswap River and Thompson River fisheries, observed catch was sampled for size, flesh colour, sex, adipose fin status and scales. In the lower Fraser River and lower Shuswap River fisheries, the surveyor evaluated the angler's ability to recall trip duration at trip's end and to predict subsequent duration when contacted during the trip.
4. Study area angler effort was estimated at 125,251 angler hours or 24,949 angler days. Of that total, 90,678 occurred on lower Fraser River, 1,832 on upper Quesnel River, 19,449 on lower Shuswap River, 12,118 on South Thompson River, and 1,174 on Thompson River. Most anglers targeted on chinook salmon.
5. Study area harvest was estimated at 1,805 chinook adults, 159 chinook jacks, 8 sockeye salmon, 125 rainbow trout and 8 whitefish. Of the chinook adult harvest, 1,282 were from lower Fraser River, 40 from upper Quesnel River, 120 from lower Shuswap River, 259 from South Thompson River and 104
from Thompson River. A total of 101 chinook adults had adipose fin clips, 72 in lower Fraser River, 10 in lower Shuswap River and 19 in Thompson River.
6. Study area release was estimated at 159 chinook adults, 57 chinook jacks, 3 sockeye salmon and 3 rainbow trout. Chinook adults were released in lower Fraser (116), South Thompson (3) and Thompson (40) rivers.
7. Chinook adult harvest rates ranged from $1.1 \%$ to $2.5 \%$. The highest harvest rates were recorded in the South Thompson and Thompson rivers.

## ACKNOWLEDGENENTS

Field work was conducted by $N$. Brooks, W. Dale, A. Dickinson, D. Edmonds, I. Fortin, T. Hobbs, L. Hughes, H. Lackoe, T. Madden, P. Mathew, D. Moore, D. O'Reilly, J. Pierce, S. Ratcliffe, L. Samaha, H. Spiers, J. Stepp, G. Stevens, B. Williams and L. Young. Figures were drafted by $S$. Gramchuk. The manuscript was prepared for publication by M. Winkelmans.

The assistance of the following organizations is gratefully acknowledged: the Quesnel River Hatchery, especially R. Dickson, for assistance with the Quesnel River study; the Kingfisher Fish and Game Club for assistance with the Shuswap River study; the Shuswap Nation Tribal Council for assistance with the South Thompson River study; and the Spences Bridge residents and Spius Creek Hatchery staff, especially N. Todd, for assistance with the Thompson River survey. Special thanks are extended to the anglers of the lower Fraser, Quesnel, Shuswap, South Thompson and Thompson rivers for providing the information which formed the basis for this study.

a. Nicola River Mouth only.

Appendix 20. Variance estimation procedure for acess point surveys (adapted from DPA Group Inc. (MS 1985a)).

CATCH (C)

$$
\begin{equation*}
\operatorname{Var}(C)=\bar{C}^{2} E^{2}\left[\frac{\operatorname{Var}(E)}{E^{2}}+\frac{\operatorname{Var}(\bar{C})}{\bar{C}^{2}}+\frac{\operatorname{Var}(E) \operatorname{Var}(\bar{C})}{\bar{C}^{2} E^{2}}\right] \tag{1}
\end{equation*}
$$

where: $E \quad=$ estimate study period effort (hours);
$\operatorname{Var}(E) \quad=$ variance of the estimated study period effort (Equation 2)
$\overline{\boldsymbol{c}} \quad=$ estimated study period catch per angler hour;
$\operatorname{Var}(\bar{C})=$ variance of the estimated study period catch per angler hour (Equation 3).

EFFORT (E)

$$
\begin{equation*}
\operatorname{Var}(E)=N^{2}\left[\frac{\bar{y}_{j}^{\star}}{\bar{p}_{j}^{\star}}\right]^{2}\left[\frac{\operatorname{Var}\left(\bar{y}_{j}^{\star}\right)}{\bar{y}_{j}^{\star^{2}}}+\frac{\operatorname{Var}\left(\bar{p}_{j}^{\star}\right)}{{\overline{p_{j}}}^{\star^{2}}}-\frac{2 \operatorname{Cov}\left(\bar{y}_{j}^{*}, \bar{p}_{j}^{*}\right)}{\left(\bar{y}_{j}^{*}\right)\left(\bar{p}_{j}^{\star}\right)}\right] \tag{2}
\end{equation*}
$$

where: $N=$ total days in the study period;
$\bar{y}_{j}{ }^{*} \quad=$ mean instantanous rod count (hour $j^{*}$ );
Var $\bar{y}_{j}^{*}=$ variance of the mean rod count at hour $j^{*}$ (Equation 4);
$\bar{p}_{\boldsymbol{j}}{ }^{*} \quad=$ proportion of daily angler hours occurring at the time of the instantaneous rod count;
Var $\bar{p}_{j}^{*} \quad=$ variance of the proportion of daily angler hours occurring at the time of the instantaneous rod count (Equation 5).

## CATCH PER UNIT EPFORT ( $\bar{C}$ )

Beacause $\bar{C}$ is a ratio of catch to time of interview ( $\hat{X}$ ) and time fished to time of interview ( $\hat{\mathrm{T}}$, a Taylor series approximation to the variance of the ratio of random variables was used. Because we expected to interview a relatively large proportion of the anglers, especially at the access point sites, the greatest variance was expected to occur at the stint level; consequently, the following estimate embodies only that sampling stage.

$$
\begin{equation*}
\operatorname{Var}(\bar{C})=\left[\frac{\hat{X}}{\hat{T}}\right]^{2}\left[\frac{\operatorname{Var}(\hat{X})}{\hat{X}^{2}}+\frac{\operatorname{Var}(\hat{n})}{f^{2}}-\frac{2 \operatorname{Cov}(\hat{X}, \hat{i})}{(\hat{X})(\hat{X})}\right] \tag{3}
\end{equation*}
$$

$$
\operatorname{Var}(\hat{X})=\sum_{i} \sum_{1} N^{2}\left(1 / n_{i j}-1 / N\right) \sum_{f} \quad\left[\frac{\left(\hat{X}_{11 f}-\left(1 / n_{1 f} \sum_{f} \hat{X}_{11 f}\right)\right)^{2}}{n_{1 j}-1}\right]
$$

$\operatorname{Var}(\hat{T})$ is analogous to above.

$$
\hat{X}_{11 f} \quad=\text { estimated total catch for the } f^{\text {th }} \text { stint of the } 1^{\text {th }} \text { stint type }
$$ at the $i^{\text {th }}$ site;

```
finf}== estimated total angler hours for the fith stint of the 1 1 %
    stint type at the i }\mp@subsup{i}{}{\mathrm{ th }}\mathrm{ site;
nij = number of interview sample days at site i on hour j.
```

MEAN INSTANTANEOUS ROD COUNT ( $\bar{y}_{j}{ }^{*}$ )

$$
\begin{equation*}
\operatorname{Var}\left(\bar{y}_{j}^{\star}\right)=\left(1 / n_{j}^{\star}-1 / N\right) \sum_{k}\left[\frac{\left(y_{j}^{\star} k-\bar{y}^{\star}\right)^{2}}{n_{y}^{\star}-1}\right] \tag{4}
\end{equation*}
$$

where:

$$
\begin{array}{ll}
\bar{n}_{y}^{*} & \text { number of instantaneous rod counts at hour } j^{*} ; \\
y_{y}^{*} k & =\text { instantaneous rod count (all sites) on day } k ; \\
\bar{y}_{y}^{*} k & =\text { estimated mean rod count at hour } j^{*} .
\end{array}
$$

PROPORTION OF DAILY EFFORT AT TIME OF INSTANTANEOUS ROD COUNT ( $\bar{p}_{j}^{*}$ ).
Because $\bar{p}_{j}{ }^{*}$ is a ratio of $\hat{R}_{j}$ and $\mathcal{\sum} R_{j}$ the following Taylor series approximation to the variance of the ratio of random variables was used:

$$
\begin{equation*}
\operatorname{Var}\left(\bar{R}_{j}^{\star}\right)=\left[\frac{\hat{R}_{j}^{*}}{\sum_{j} \hat{R}_{j}}\right]^{2}\left[\frac{\operatorname{Var}\left(\hat{R}_{j}^{*}\right)}{\hat{R_{j}{ }^{2}}}+\frac{\operatorname{Var} \sum_{j} \hat{R}_{j}}{\sum_{j} \hat{R}_{j}^{2}}-\frac{2 \operatorname{Cov}\left(\hat{R}_{j}{ }^{2}, \sum_{j} \hat{R}_{j}\right)}{\left(\hat{R}_{j}^{\star}\right)\left(\sum_{j} \hat{R}_{j}\right)}\right] \tag{5}
\end{equation*}
$$

where:

$$
\begin{aligned}
& \operatorname{Var}\left(\hat{R}_{j}^{\star}\right)=\sum_{1} N^{2}\left(1 / n_{i j}^{*}-1 / N\right) \sum_{k}\left[\frac{\left(n_{i j_{k}}-\left(1 / n_{i j}{ }^{*} \sum_{k} r_{y_{k}{ }_{k}}\right)^{2}\right.}{n_{i j}^{*}-1}\right]
\end{aligned}
$$

$\operatorname{Var} \sum_{\boldsymbol{j}} \hat{R}_{\boldsymbol{j}}$ is analagous to above.

| $N$ | umber of days in stratum; |
| :---: | :---: |
| $n_{11}{ }^{*}$ | $=$ number of interview sample days at site $i$; |
| $r_{1 j k}$ | $=$ rod count at site $i$ at hour $j$ on day $k$; |
| $r_{1 j}{ }^{*} k$ | $=$ rod count at site $i$ on day $k$ at the hour of the |
| $\hat{R}_{j}{ }^{*}$ | ```instantaneous effort count; = estimated total effort (hours) during the instantaneous rod count time block;``` |
| $\sum_{j} \hat{R}_{j}$ | = estimated total effort over all hours and days at the site surveyed. |

[^0]:    a. Assessed in June and July (61 days) only.
    b. Martel fishery closed on July 30.
    c. Reduced to 1 day per week after July 30 ; daily fishing time increased by 7 hours (from 6 a.m. - 2 p.m. to 6 a.m. - 9 p.m.).

[^1]:    a. Includes 42 with adipose fin clips. c. Includes 10 with adipose fin clips
    b. Includes 30 with adipose fin clips. d. Includes 19 with adipose fin clips

[^2]:    a. Angler day length is weighted by site; all other data are unweighted.
    b. Includes rainbow, whitefish or Dolly Varden.

[^3]:    The 1987 upper Fraser River sport fishery study identified a negative bias in HPUE estimated from

[^4]:    a. Combined indicates complete and incomplete trip interviews
    b. Not weighted by day type or site.
    c. Previous trip data unavailable.

[^5]:    a. Weighted; see Methods.

[^6]:    a. C - clear; 0 - overcast; R - rain.
