#### Abstract

Schubert, N.D., M.K. Farwell, and L.W. Kalnin. 1994. A coded wire tag assessment of Salmon River (Langley) coho salmon: 1992 tag application and 1993-1994 spawner enumeration. Can. Manuscr. Rep. Fish. Aquat. Sci. 2241: 33 p.

In 1986, the Department of Fisheries and Oceans implemented a plan to improve the assessment data for coho salmon (Oncortynchus kisutch) through the long term evaluation of key stocks. The Salmon River (Langley) was selected for the evaluation, with known precision, of annual escapement, marine survival, harvest distribution and exploitation rate. In the spring of 1992, an estimated 28,141 (corrected for $8.8 \%$ long term tag loss) coho smolts were released with coded wire tags at an average size of 91.5 mm and 7.8 g . The adult escapement was estimated in fall and winter of 1993-1994 using the Petersen mark-recapture method. Escapement was estimated at 5,913 coho adults of which 1,079 had coded wire tags and 105 had lost the coded wire tag. Smolt to adult escapement survival averaged 3.8\%.

Escapement progressively declined over the 1984-1989 brood years, from 11,947 in 1987 to 2,604 in 1992. In 1993, escapement increased to 5,913 but remained below the 1987-1992 average of 6,899.

Key Words: Coho salmon, Salmon River (Langley), key stream, coded wire tag, escapement, survival, exploitation rate.

## RÉSUMÉ

Schubert, N.D., M.K. Farwell, and L.W. Kalnin. 1994. A coded wire tag assessment of Salmon River (Langley) coho salmon: 1992 tag application and 1993-1994 spawner enumeration. Can. Manuscr. Rep. Fish. Aquat. Sci. 2241: 33 p.

En 1986, le ministère des Péches et Océans a entrepris une évaluation à long terme des stocks clés pour améliorer la base de données sur le saumon coho (Oncorhynchus kisutch). Il a choisi de faire cette évaluation dans la rivière Salmon (Langley) et d'établir des données précises sur l'échappée annuelle, la survie, la répartition des captures et le taux d'exploitation. Au printemps de 1992, environ 28141 (chiffre ajusté pour tenir compte des pertes à long terme de micromarques magnétisées codées, 8,8\%) jeunes saumons mesurant en moyenne $91,5 \mathrm{~mm}$, pesant en moyenne $7,8 \mathrm{~g}$, et pourvus d'une micromarque magnétisée codée ont été relâchés. L'échappée des adultes a été estimée à l'automne et au hiver de 1993-1994 au moyen de la technique Petersen de marquage-recapture. L'échappée a été estimée à 5913 poissons, dont 1079 avaient encore leur micromarque et 105 l'avaient perdue. Le taux de survie des jeunes saumons atteignant l'échappée des adultes de 3,8\%.

L'échappé a subit une baisse progressive de 1984 à 1989, de 11947 poissons en 1987 à 2604 poissons en 1992.

Mots clés: Saumon coho, rivière Salmon (Langley), cours d'eau important, micromarque magnétisée codée, échappée, survie, le taux d'exploitation.

## INTRODUCTION

In 1986, the Department of Fisheries and Oceans implemented a plan to improve coho salmon (Oncorhynchus kisutch) assessment data through the long term evaluation of key stocks. The Salmon River was selected for the evaluation, with known precision, of annual escapement, marine survival, harvest distribution, and exploitation rate. This stock was selected for three reasons. First, because recent escapements comprised 4\% of the Fraser River total (Farwell et al. 1987), the status of Salmon River coho was an important measure of the status of the Fraser River coho resource. Second, 1976-1978 brood year studies (Schubert 1982; Schubert and Fleming 1989) provided a time series of comparable escapement, survival and exploitation rate data. Third, manageable logistics limited project costs.

This report documents, for the 1990 brood, the 1992 smolt coded wire tag (CWT) application and the 1993-1994 aduft escapement estimation studies. Previous reports documented the evaluation of the 1984-1989 brood years (Schubert and Kalnin 1990; Farwell et al. 1991, 1992a, 1992b; Kalnin and Schubert 1991; Schubert et al. 1994). This report describes the field methods, analytic techniques and study results, including smolt timing, age and size as well as adult age, length, sex, adipose fin clip (AFC) incidence, escapement estimates and long term CWT loss. The study did not estimate the escapement of precocious males (jacks). The report includes a discussion of data limitations and a synthesis of study results for the 1984-1990 brood years.

## STUDY AREA

The Salmon River flows northwest for 33 km, entering the Fraser River west of Fort Langley, B.C. (Fig. 1). Coghlan Creek, the principal tributary, joins the mainstem 14 km upstream from the Fraser River. The system, with an average annual discharge of $1.41 \mathrm{~m}^{3} \cdot \mathrm{~s}^{-1}$ (Environment Canada 1980), drains $85 \mathrm{~km}^{2}$ of agricultural and residential land. During the Fraser River spring freshet, the Salmon River flows through a pumphouse located at the river mouth. Because no provisions were made for fish passage, up to $31 \%$ of the coho smolts are killed as they pass through the pumps (Russell MS 1981). The study area was divided into ten reaches, five in the Salmon River and five in

Coghlan Creek (Fig. 1). Reaches were established to accommodate statistical tests for bias rather than on the basis of homogeneity of physical characteristics. In most study reaches, the river flows across low gradient terrain in a shaded, meandering channel with a gravel substrate. The only exceptions are reaches C5 and S5 where the river is marshy and summer flows are low.

## FIELD METHODS

## SMOLT CAPTURE

Fence traps similar to those described by Schubert (1982) operated in the Salmon River ( 30 m above the Coghlan Creek confluence) and in Coghlan Creek ( 30 m above the Salmon River confluence) from April 16 to June 1, 1992. Captured fish were enumerated at least once daily. Coho smolts were transferred to holding boxes or to the tagging site for tagging and sampling. Coho fry were not enumerated because the 6 mm fence mesh did not fully restrict their passage. The remaining catch was identified to species and released below the fence. Steelhead ( $O$. mykiss) and cutthroat ( $O$. clark) trout were recorded as smolt or presmolt. Trout smolts had a silver coloration and nose-fork (NF) length greater than 110 mm . Presmolts had distinct parr marks and a length of less than 110 mm .

## CODED WIRE TAG APPLICATION

The CWT equipment and methods were described by Armstrong and Argue (1977). Coded wire tagging occurred from April 21 to June 1, 1992 at intervals of one to five days. On each day, smolts were sorted by size (NF length greater or less than 100 mm ) and separate nose moulds and implant depths were used for each group. Implant depth was checked by bisecting the skull of a tagged smolt along the medial plane. If the CWT was not in the preferred position in the cartilaginous wedge of the skull, the implant depth was adjusted and the procedure repeated until CWT placement was correct. The nose mould was then marked to ensure correct placement following nose mould changes. The smolts were anaesthetized with Tricaine Methane Sulfonate (TMS), marked by adipose fin removal, coded wire tagged and passed through a quality control device to ensure the CWT was present. Any diseased, damaged or undersize (NF length less than 55 mm ) smolts were released untag-

ged. A sample of approximately 200 smolts was removed from the recovery bucket and retained for 24 hours to assess AFC quality, delayed mortality and CWT loss. Any smolt without a CWT or with a poor AFC was retagged or reclipped.

## SMOLT TRANSPORT

To avoid pump mortality, the coho smolts were transported to and released at the river mouth, either immediately after tagging or in the moming when water temperatures were lower. The smolts were transported in a 180 litre plastic container supplied with air from a 12 volt air pump. Transport required less than 15 minutes.

## SMOLT SAMPLING

Fifty coho smolts per site were sampled twice weekly for scales, length and weight. The smolts were anaesthetized with TMS, a scale smear was removed with a scalpel from each side of the fish, NF length was measured to the nearest millimetre, and mean wet weight ( $\pm 0.1 \mathrm{~g}$ ) was determined in aggregate using a triple beam balance.

## ADULT CAPTURE

Coho adults were captured in reaches S1 to S5 and C1 to C5 (Fig. 1) from October 27 to December 20, 1993. Coho were attracted from log jams and cut banks with a Smith Root Model $12^{\circ} 24$-volt direct current electroshocker. Voltage, amperage, pulse with and frequency were adjusted daily to minimize visible damage (body bruising) while providing sufficient torpor to permit capture. Shocked coho adults (NF length greater than 30 cm ) were captured in a dip net, permitted to recover in a 60 litre container of water, marked and released.

Coho adults were marked with Petersen disk tags in a wooden tray ( $10 \mathrm{~cm} \times 10 \mathrm{~cm} \times 100$ cm ) constructed with a flexible plastic bottom and a metre stick recessed in one side. The tags consisted of two 22 mm diameter laminated cellulose acetate disks and one 7 mm diameter transparent plastic buffer disk threaded through centrally punched holes onto a 77 mm long nickel pin. The pin was inserted with pliers through the musculature and pterygiophore bones approximately 12 mm below the anterior portion of the dorsal fin insertion. The disk tags, arranged with
one on each side of the fish and with a buffer disk on the pin head side, were secured by twisting the pin into a double knot. One disk per pair was numbered with a unique code. Green tags were used to reduce colour contrast, thereby minimizing recovery and predation biases. Each tagged fish received a secondary mark, a 7 mm diameter hole punched through the right operculum using a single hole paper punch, to allow the estimation of tag loss. Males and females received one and two punches, respectively, to permit the estimation of sex identification error. Care was taken to avoid gill tissue damage. Date and location (reach) of capture, disk tag number, NF length ( $\pm 0.5 \mathrm{~cm}$ ), sex and adipose fin status were recorded for each fish released with a disk tag. Activity at release was recorded as 1 (swam away vigorously), 2 (swam away sluggishly) or 3 (required ventilation). Electroshocker bruising to the body was recorded as 0 (none), 1 (faint bruise), 2 (bruise up to 25 mm in diameter), 3 (bruise over 25 mm in diameter). Recovered disk tagged carcasses were enumerated and sampled (described below) to assess handling mortality.

## SPAWNING GROUND SURVEYS

The spawning grounds were surveyed weekly from November 10, 1993 to January 21, 1994. Complete surveys, conducted by a two to four person crew walking upstream, required up to two days. Live adults were counted and carcasses were recorded by date, reach, sex (confirmed by abdominal incision) and mark type (disk tag, secondary mark or AFC). Each marked carcass and every tenth unmarked carcass was sampled. All carcasses were then cut in two with a machete and returned to the river. Sample data, recorded by date and reach, included post-orbital-hypural plate (POH) length (to the nearest 0.1 cm ), sex, female spawning success ( $0 \%, 50 \%$ or $100 \%$ spawned), adipose fin and carcass condition, and scale samples. For AFC coho, the head was removed posterior to the eye orbit for later CWT identification. Adipose fin condition was recorded as unclipped, complete (flush with dorsal surface), partial (nub present) or questionable (appeared clipped but fungus or decomposition obscured the area). The condition of AFC carcasses was recorded as fresh (gills red or mottled), moderately fresh (gills white, body firm), moderately rotten (body intact, flesh soft) or rotten (skin and bones), and the absence of one or both eyes was noted.

## ANALYTIC PROCEDURES

## TESTS FOR SAMPLING SELECTIVITY

## Period

Temporal bias was assessed using a chisquare test (Sokal and Rohlf 1981). Application bias was examined by comparing between periods the mark incidence in the recovery sample, where mark incidence was the proportion of the coho adults marked with either a disk tag or a secondary mark. Recovery bias was examined by stratifying the application sample by period and comparing proportions recovered.

## Location

Spatial bias was similarly assessed in the application sample by comparing between sections the mark incidence in the recovery sample. Recovery bias was examined by stratifying the application sample by section and comparing the proportions recovered.

## Fish Size

Size related bias was assessed using the Kolmogorov-Smirnov two-sample test (Sokal and Rohlf 1981). Application bias was examined by comparing the POH length-frequency distributions of marked and unmarked spawning ground recoveries. Recovery bias was examined by partitioning the application sample into recovered and non-recovered components and comparing the NF length-frequency distributions of each.

## Fish Sex

Sex related bias was assessed using chisquare tests. Application bias was examined by comparing the sex ratio of the marked and unmarked spawning ground recoveries. Recovery bias was examined by partitioning the application sample into recovered and non-recovered components and comparing the sex composition in each.

## Other Tests

Bias resulting from tagging stress was also assessed using chi-square tests as above. The application sample was partitioned into those fish which required ventilation at release and those
which did not, and those with electroshocker bruising at release and those with none. Recovery rates were compared in each group. As well, spawning success was compared in marked and unmarked spawning ground recoveries.

## ESTIMATION OF SPAWNER POPULATION

## Total Escapement

The 1993-1994 escapement of Salmon River coho adults was calculated from the markrecapture data using the Petersen formula (Chapman modification) (Ricker 1975). Total escapement was the sum of escapement by sex:

1) Estimated Salmon River system coho escapement $\left(\mathrm{N}_{\mathrm{t}}\right)$ :

$$
N_{t}=N_{m}+N_{f}
$$

where:

$$
\begin{aligned}
& \mathrm{N}_{\mathrm{m}}= \text { estimated escapement of adult } \\
& \text { males; }
\end{aligned}
$$

$$
=\frac{\left(M_{m}+1\right)\left(C_{m}+1\right)}{\left(R_{m}+1\right)}
$$

$$
\begin{aligned}
\mathbf{N}_{\mathrm{f}}= & \text { estimated escapement of females, } \\
& \text { analogous to above. }
\end{aligned}
$$

2) Ninety-five percent confidence limits of $\mathrm{N}_{\mathrm{t}}$ :

$$
N_{t} \pm 1.96 \sqrt{V_{t}}
$$

where:

$$
\begin{aligned}
\mathbf{N}_{\mathrm{t}} & =\text { total escapement estimate; } \\
\mathrm{V}_{\mathrm{t}} & =\text { variance of the escapement esti- } \\
& \text { mate; } \\
& =\mathrm{V}_{\mathrm{m}}+\mathrm{V}_{f} \\
\mathrm{~V}_{\mathrm{m}} & =\begin{array}{l}
\text { variance of the adult male es- } \\
\text { capement estimate; }
\end{array} \\
& =\frac{\left(\mathrm{N}_{\mathrm{m}}^{2}\right)\left(\mathrm{C}_{\mathrm{m}}-\mathrm{R}_{\mathrm{m}}\right)}{\left(\mathrm{C}_{\mathrm{m}}+1\right)\left(\mathrm{R}_{\mathrm{m}}+2\right)} \\
& =\text { adult male escapement estimate; } \\
\mathrm{N}_{\mathrm{m}} & = \\
\mathrm{C}_{\mathrm{m}} & =\begin{array}{l}
\text { number of adult male carcasses } \\
\text { examined for disk tags; }
\end{array} \\
\mathrm{R}_{\mathrm{m}} & =\begin{array}{l}
\text { number of disk tagged or sec- } \\
\text { ondary marked males recovered; }
\end{array}
\end{aligned}
$$

$\begin{aligned} \mathrm{V}_{\mathrm{f}}= & \text { variance of female escapement } \\ & \text { estimate, analogous to above. }\end{aligned}$

## Sex Identification Correction

The tag application data were corrected for sex identification error. Error occurred because the development of sexually dimorphic traits was often not advanced and internal examinations could not be made. The correction of the recovery data was unnecessary because all carcasses were incised and examined internally. Sex identification error was corrected as described by Staley (1990):
3) Estimated true number of males released with disk tags and secondary marks ( $\mathrm{M}_{\mathrm{m}}$ ):

$$
M_{m}=\frac{M_{m}^{*}-\left(M_{t} R_{m f}\right) / R_{f}}{1-\left(R_{m f} / R_{f}\right)-\left(R_{f, m} / R_{m}\right)}
$$

where:

$$
\left.\left.\begin{array}{rl}
\mathrm{M}_{\mathrm{m}}^{*}= & \text { field estimate of the number of } \\
& \text { males released with disk tags and } \\
& \text { secondary marks; }
\end{array}\right\} \begin{array}{rl} 
\\
\mathrm{M}_{\mathrm{t}}= & \text { total number of coho adults re- } \\
& \text { leased with disk tags and secon- } \\
& \text { dary marks; }
\end{array}\right\}
$$

4) Estimated true number of females released with disk tags and secondary marks ( $\mathrm{M}_{\mathrm{f}}$ ):

$$
\mathbf{M}_{\mathbf{f}}=\mathbf{M}_{\mathbf{t}}-\mathbf{M}_{\mathbf{m}}
$$

## Adipose Fin Clipped Escapement

We estimated the AFC escapement from the AFC incidence in the carcass recovery sample, the largest of the two available samples. The AFC incidences in the Salmon River and Coghlan Creek were first tested for significant differences using a chi-square test. If no differ-
ence was noted, the AFC escapement was the product of the pooled AFC incidence and the mark-recapture escapement estimate. Ninety-five percent confidence limits were calculated from the respective upper and lower confidence limits of the AFC incidence and the escapement estimate. For example, the upper $95 \%$ confidence limit of the AFC escapement estimate was the product of the upper limit of the AFC incidence and the upper limit of the total mark-recapture estimate. The mathematical relationships are reported below (Cochran 1977):
5) Estimated AFC escapement $\left(\mathbf{N}_{\mathrm{a}}\right)$ :

$$
N_{a}=p\left(N_{t}\right)
$$

6) Ninety-five percent confidence limits for p:

$$
p \quad \pm \quad 1.96(s e+f p c)
$$

where:

$$
\begin{aligned}
\mathbf{p} & =\text { sample proportion with an AFC; } \\
\mathbf{s e} & =\text { standard error; } \\
& =(1-\mathrm{f}) \mathrm{pq} /(\mathrm{n}-1) \\
\mathbf{f p c} & =\text { finite population correction; } \\
& =\frac{1}{2 n} \\
\mathbf{n} & =\text { sample size; } \\
\mathbf{q} & =1-\mathrm{p} \\
\mathbf{f} & =\frac{\mathbf{n}}{\mathbf{N}_{\mathbf{t}}}
\end{aligned}
$$

If the Salmon River and Coghlan Creek AFC incidences differed, then the AFC escapement estimate was the product of the stream-specific total escapement, the stream-specific AFC incidence, and the pooled CWT retention level. Total escapement by stream was calculated by applying the ratio of the stream-specific Schaefer estimates to the Petersen estimate. Confidence limits, therefore could not be reported for the AFC escapement using this method.

## Coded WIre Tagged Escapement

Escapement by CWT code and long term CWT loss were calculated by applying the CWT composition in the carcass recovery sample to the estimated escapement of AFC adults. Apparent CWT loss was adjusted for post-mortality loss resulting from carcass decomposition and predator activity, where appropriate.

## HARVEST SAMPLING

This report provides estimates of total CWT harvest for the 1984-1989 brood years. The harvest data were obtained from the regional mark recovery program data base (Kuhn et al. 1988) and were treated for sampling problems as described by Schubert et al. (1994). Harvest estimates for the 1990 brood year are unavailable but will be provided in next year's report.

## RESULTS

## SMOLT CAPTURE

Catch of coho smolts totalled 34,707 in 1992, 17,396 in Salmon River and 17,311 in Coghlan Creek (Appendix 1). The 50\% migration and the peak daily catch occurred on May 6 and April 27, respectively, in the Salmon River and on May 7 and May 6, respectively, in Coghlan Creek. High discharges rendered the traps inoperable for seven days (April 29 to May 5) in the Salmon River and seven days (April 18 and April 29 to May 4) in Coghlan Creek. The reported timing of the 1992 smolt migration, therefore, may be somewhat biased.

## CODED WIRE TAG APPLICATION

AFC and CWT releases totalled 31,384 coho smolts in 1992 (Appendix 2). When adjusted for long term CWT loss (8.8\%) (Appendix 9) and short term (24-hour) post tagging mortality (Appendix 2), the number released with CWTs and identifiable AFCs was $\mathbf{2 8 , 1 4 1}$. Short term CWT loss averaged $1.1 \%$ (range $0.0 \%$ to $6.2 \%$ ) (Appendix 2). The incidence of disease, damage, or structural anomalies averaged $14.5 \%$ (Appendix 3). The most prevalent condition was 'fog eye' (14.1\%), a reversible condition associated with capture stress. Seven naturally missing adipose fins ( $0.02 \%$ ) were observed.

## COHO SMOLT AGE AND SIZE

Of the smolts sampled emigrating from the Salmon River system, $0.7 \%$ were age $0+$, $98.8 \%$ were age $1+$ and $0.5 \%$ were age $2+$. Smolt size averaged 90.0 mm and 7.5 g in the Salmon River and 93.0 mm and 8.1 g in Coghlan Creek (Appendix 4). Weighted mean smolt size was 91.5 mm and 7.8 g . Smolt size declined through the migration period.

## DISK TAG APPLICATION

Disk tags and secondary marks were applied to 490 coho adults in the Salmon River system from October 27 to December 20, 1993 (Appendix 5); 78 (15.9\%) had an AFC. Three hundred and forty-two tags ( $69.8 \%$ ) were applied in the Salmon River and 148 (30.2\%) in Coghlan Creek; most were released in reaches S1 (41\%), C1 (21\%) and S3 (16\%).

Sixty fish (12.2\%) required ventilation at release; however, the proportion of this group recovered ( $21.7 \%$ ) was not significantly different ( $p>0.05$; chi-square) from the remaining fish ( $16.5 \%$ ) (Table 2). Electrochocker bruising was noted in 270 fish (55.2\%) (Table 2); however, the proportion of this group recovered (17.4\%) was not significantly different ( $p>0.05$; chi-square) than the unbruised group ( $16.4 \%$ )(Table 2). Consequently, neither of these groups of fish were removed from the application sample.

An estimated $2.4 \%$ of the females and none of the males were misidentified at the time of tagging (Appendix 6). When adjusted for this error, an estimated 283 (57.8\%) males and 207 ( $42.2 \%$ ) females were released with disk tags and secondary marks (Table 1).

The mean NF length of females ( 54.0 cm ) was significantly larger ( $\mathrm{p}<0.05$; ANOVA) than males ( 51.8 cm ) and, in both sexes, fish with AFCs (males 50.5 cm , females 52.5 cm ) were smaller than unmarked fish (males 52.0 cm , females 54.3 cm ). This difference was significant ( $p<0.05$ ), however, only in females.

In 1993-1994, 11 previously tagged fish were recaptured in later capture efforts. Recaptures were not recorded after November 15; therefore, this figure is not representative of vulnerability of marked fish to repeated capture.

## SPAWNING GROUND RECOVERY

One thousand and forty-six adults and 1 jack were recovered on the spawning grounds from November 10, 1993 to January 21, 1994 (Table 1; Appendix 7). Of the adults identified to sex, 490 ( $47.0 \%$ ) were male and 553 ( $53.0 \%$ ) were female; 209 ( $20.0 \%$ ) of the adults had an AFC, 81 ( $7.7 \%$ ) had a disk tag and secondary mark, $3(0.3 \%)$ had no secondary mark and none

Table 1. Disk tag application, carcass examination and mark recovery, by sex, of Salmon River system coho adults, 1993-1994.

| Sex | Disk tags applied a | Carcasses examined | Marks recovered |  |  |  | Percent recovered |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Disk tag and secondary mark | Secondary mark only | $\begin{gathered} \text { Disk } \\ \text { tag only } \\ \hline \end{gathered}$ | Total |  |
| Male | 283 | 490 | 41 | 0 | 2 | 43 | 14.8\% |
| Female | 207 | 553 | 40 | 0 | 1 | 41 | 19.8\% |
| Total | 490 | $1,046 \mathrm{~b}$ | 81 | 0 | 3 | 84 | 17.1\% |

had lost a disk tag. The proportion of disk tagged fish which was recovered was significantly higher ( $p>0.05$; chi-square) in those with AFCs ( $29.5 \%$ ) than in those without an AFC (14.8\%).

The distribution of recoveries was 518 adults (49.4\%) in the Salmon River and 528 (50.5\%) in Coghlan Creek. Most were recovered in reaches C1 ( $21 \%$ ), S4 (19\%), S3 (13\%) and C2 (12\%).

## Age, Length and Sex

The age and length of the 1993-1994 spawning ground recoveries are reported in Appendix 8 . Age $3_{2}$ fish comprised $98.9 \%$ of the adult males and $96.5 \%$ of the females. No difference in age composition was noted between streams or by AFC status ( $p>0.05$; chi-square). The mean POH length of females ( 43.9 cm ) was significantly larger ( $p<0.05$; ANOVA) than that of males ( 41.4 cm ). In both sexes, fish with AFCs (males 41.0 cm , females 43.3 cm ) were smaller than unmarked fish (males 41.9 cm , females 44.8 cm ); however, the difference was significant ( $\mathrm{p}<$ 0.05 ; ANOVA) only in females.

## Coded Wire Tag Recoverles

Eighty-eight adult males and 120 females were recovered with an AFC, an incidence of $18.0 \%$ and $21.7 \%$, respectively. The AFC incidence was not significantly different ( $p>0.05$; chi-square) between streams or sexes (Appendix 9). CWTs were recovered from 71 adult males
and 69 adult females; all were 1990 brood Salmon River system coho. There was a significant difference ( $p<0.05$; chi-square) in the spatial distribution of the CWT codes released at a single site. Recoveries in the Salmon River were largely ( $77.5 \%$ ) of Salmon River origin, while those in Coghlan Creek were largely (91.7\%) of Coghlan Creek origin (Appendix 9). There was no difference ( $p>0.05$; chi-square) in the temporal pattern of recoveries between CWT codes.

CWT loss was lower in carcasses with both eyes ( $18.0 \%$ ) versus those missing one or both eyes (41.2\%) (p < 0.05; chi-square) (Appendix 10), indicating that predators biased the CWT loss estimate by removing CWTs embedded in the eye or surrounding tissue. A significant difference ( $p<0.05$ ) was also noted between fresh (19.0\%) and decomposed (44.7\%) carcasses, and between carcasses with complete or partial (12.7\%) and questionable (54.9\%) AFCs (Appendix 10). When carcasses in the rotten, eye missing and questionable AFC categories were removed from the sample, the adjusted long term CWT loss was $8.8 \%$. No difference ( $p>0.05$; chi-square) in CWT loss was noted between the study streams or between sexes (Appendix 9).

## SAMPLING SELECTIVITY

## Period

Temporal bias in the application sample was examined by comparing mark incidences in

three recovery periods (Table 3). Mark incidences ranged from $6.5 \%$ to $18.1 \%$, but the differences were significant ( $p<0.05$; chi-square) only in males. The highest mark incidences occurred in the early recovery period.

Recovery bias was examined by comparing the proportions recovered from three application periods (Table 4). The proportions ranged
from $4.8 \%$ to $27.8 \%$, but the differences were not significant ( $p>0.05$ ) in either sex.

## Location

Spatial bias in the application sample was examined by comparing the mark incidences in five recovery sections (Table 5). Mark incidence ranged from $0.9 \%$ to $\mathbf{2 4 . 1 \%}$; the differences were

Table 10. Escapement estimates and 95\% confidence limits, by sex and age, for Salmon River system coho adults, 1993-1994.

| Group | Escapement by age |  |  | 95\% confidence limits on escapement estimate |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 3/2 | 4/3 | Total | Lower | Upper |
| Male | 3,133 | 36 | 3,169 | 2,286 | 4,053 |
| Female | 2,648 | 96 | 2,744 | 1,955 | 3,532 |
| Total | 5,781 | 132 | 5,913 | 4,729 | 7,097 |

significant ( $p<0.05$; chi-square) in both sexes. The mark incidences were highest in the lower sections of Salmon River.

Recovery bias was examined by stratifying the application sample into five sections and comparing the proportions recovered (Table 6). The proportions ranged from $10.7 \%$ to $44.4 \%$; however, the differences were not significant (p $>0.05$ ) in either sex.

Fish Size
Size related bias in the application sample was examined by comparing POH lengthfrequency distributions of marked and unmarked spawning ground recoveries. No significant difference ( $p>0.05$; Kolmogorov-Smirnov twosample test) was noted in males or females.

Recovery bias was examined by partitioning the application sample into recovered and non-recovered components and comparing NF length-frequency distributions of each. No significant difference ( $p>0.05$ ) was noted; however, when the data were stratified by 10 cm increments of nose-fork length, larger females were recovered at a significantly higher rate (Table 7).

## Fish Sex

No significant difference ( $p>0.05$; chisquare) was noted in the sex ratio of marked and unmarked spawning ground recoveries (Table 8). The application sample, therefore, was relatively unbiased with respect to sex.

No significant difference ( $p>0.05$ ) was noted in the sex ratio of the recovered and nonrecovered components of the application sample Table 8). Furthermore, no difference was noted in the proportion of males ( $14.8 \%$ ) and females (19.8\%) released with disk tags and recovered on the spawning grounds (Table 1). We concluded, therefore, that the recovery sample was relatively unbiased with respect to sex.

## Spawning Success

Spawning success, estimated from the internal examination of female spawning ground recoveries, was estimated at 96.9\% (Appendix 11). Spawning success of marked ( $94.9 \%$ ) and unmarked ( $97.4 \%$ ) females was not significantly different ( $p>0.05$; difference in proportions test).

## ESTIMATION OF SPAWNER POPULATION

## Total Escapement

Because serious spatial and temporal biases were not identified in this study (Table 9; see Discussion), escapement was calculated using the simple Petersen estimator. The 19931994 escapement of Salmon River coho adults was 5,913 (Table 10), with lower and upper $95 \%$ confidence limits of 4,729 and 7,097, respectively. The escapement of male and female coho adults was 3,169 and 2,744 , respectively. Age $3_{2}$ fish dominated the adult escapement (97.8\%); only $2.2 \%$ were age $4_{3}$.

The total escapement was allocated between the Salmon River and Coghlan Creek by applying proportions calculated from the Schaefer

Table 11. Smolt releases, adult escapement and survival to adult escapement, by location and CWT code, of 1990 brood Salmon River sysiem coho salmon.

| Location |  | CWT code |  |  | Adult escapement with an AFC but without a CWT |
| :---: | :---: | :---: | :---: | :---: | :---: |

|  | Survival to escapement | 4.0\% | 3.1\% | 4.4\% | - |

a. Adjusted for long term CWT loss.
b. Product of the stream-specific escapement, pooled AFC incidence, pooled CWT retention, and proportion by code.
stratified estimate. The Salmon River accounted for $55.2 \%(3,363)$ of the total escapement, $57.2 \%$ $(1,813)$ of the adult male escapement and $52.8 \%$ $(1,449)$ of the female escapement.

## Adipose Fin Clips and Coded Wire Tags

The AFC incidences in the Salmon River (20.7\%) and Coghian Creek (19.4\%) were not significantly different ( $p>0.05$; chi-square). The AFC escapement, therefore, was derived from the pooled AFC incidence of $20.0 \%$. The AFC escapement was 1,184 adults, with lower and upper 95\% confidence limits of 942 and 1,427, respectively. The AFC escapement by stream was the product of the Petersen estimate for the entire system and the ratio of the stream specific Schaefer estimates. Of the estimated 1,184 coho adult AFC escapement, 654 returned to the Salmon River and 530 to Coghlan Creek (Table 11). Of that total, 371 returned with code 0209 19, 302 with code 020920,406 with code 0209 21 , and 105 (8.8\%) had lost the CWT. Survival from smolt release to adult escapement averaged $3.8 \%$. There was a significant difference ( $p<$ 0.5 ; chi-square) in survival between the single site releases in Salmon River (3.1\%) and Cogh-
lan Creek (4.0\%) and between the early (3.5\%) and late (4.4\%) mixed site releases.

DISCUSSION

## PROGRAM EFFECTIVENESS

The effectiveness of the 1990 brood juvenile program can be evaluated by examining the number of smolts trapped and the AFC incidence in the subsequent adult escapement. Both the 1990 brood release of coded wire tagged coho smolts $(28,141)$ and the subsequent adult AFC incidence ( $20.0 \%$ ) were considerably higher than the previous six year average of 21,547 and $14.7 \%$, respectively (Farwell et al. 1992b; Schubert et al. 1994). This suggests that the efficiency of the 1992 trapping program was high and that smolt production remained low. The former is surprising because the traps were inoperative for seven days during the peak of migration. The latter is supported by a smolt production index calculated for the 1984-1990 brood years (Table 12). The index represents simple Petersen estimates, scaled by a factor of $10^{-5}$, using fin clipped smolts as the mark application sample and the adult recovery as the census sa-

c. Includes 57 which were recovered in 1988 at age 4.
d. Recalculated from Farwell et al. (1991) to correct an error in the mark-recapture data.
e. Currently unavallable; will be provided in next year's report.
sample. The estimates are expressed as an index because capture and tagging probably reduced the smolt to adult survival, introducing an unquantifiable positive bias in the population estimates. Despite this bias, however, the data were useful as an index of gross changes in annual smolt production because survival impacts were unidirectional and likely to have been relatively consistent from year to year. The 1990 brood smolt index of 1.52 was above the the 1989 brood index of 1.15 but was well below the 1984-1989 brood average of 1.98 .

The effectiveness of the 1990 brood adult program was evaluated by calculating the proportion of the population which was handled during tag application and carcass recovery. Tags were applied to $8.3 \%$ of the population, slightly below the study period average of $8.5 \%$ (Table 13). The proportion of the escapement censused ( $17.7 \%$ ) and of the marks recovered (17.1\%) were also slightly below the study period averages of $19.4 \%$ and $20.0 \%$, respectively. These results indicate that the 1993-1994 program periormance was about average for this study.

## MARK-RECAPTURE STUDY

Population estimates derived from markrecapture studies are susceptible to bias from a
number of sources, including: tag loss; physiological stress which can induce the emigration of tagged fish from the population or atter recapture vulnerability; and nonrepresentative tag application or recovery resulting from samples which are selective by fish size, sex or spatial and temporal run component. We evaluated the effect of capture and tagging on subsequent catchability and concluded that this assumption was not seriously violated in 1993-1994. Electroshocker induced bruising did not significantly influence subsequent catchability or survival. This is in contrast to the results of the 1992-1993 study (Schubert et al.) where bruising was positively correlated with subsequent catchability. This result suggests that this year's field settings of electroshocker current were adequate to stun the fish without significantly influencing subsequent behaviour. The similar spawning success of marked and unmarked females further supports this conclusion.

It was not possible to definitively test the representativeness of the application and recovery samples because the true population parameters were not known. Instead, we examined the samples for four biases, temporal, spatial, fish size and fish sex, as indicators of weakness in the study design. Spatial, temporal and, potentially, size biases were identified in the current
study (Table 9); however, similar biases were not present in both the application and recovery samples. Junge (1963) noted that, when nonrepresentative sampling occurs, accurate results may still be achieved if one sample is representative. Because we had no reason to believe that the samples were similarly biased, we concluded that the identified biases were unlikely to have introduced bias in the escapement estimate. We tested this assumption by calculating population estimates which were spatially and temporally stratified using Schaefer's and Darroch's techniques. These estimates differed from the simple Petersen estimate by less than $3 \%$.

## STOCK STATUS

The status of the Salmon River system coho salmon stock can be inferred from trends in adult escapement, smolt production, exploitation rate and smolt to adult survival (Fig. 2). In an evaluation of stock status through the 1989 brood year, Schubert et al. (1994) noted that an escapement collapse had occurred during a period of reduced smolt production and smolt to adult survival. They concluded that exploitation rates must be reduced for this stock to rebuild. A full reassessment of stock status based on 1990 brood year data cannot be completed because harvest data are currently unavailable; however, inferences can be made based on additional escapement and smolt production data. Escapement increased for the first time following five consecutive years of declines, but remained well below the study period average escapement. Smolt production, as indicated by the smolt production index, also increased from the record low index for the 1989 brood year; however, the trend in erosion of smolt production noted by Schubert et al. (1994) does not appear to have been halted. Until harvest data become available, we are unable to identify the reason for the improved escapement in 1993-1994, whether increased smolt production, increased smolt to adult survival, or decreased exploitation rate. Based on the available data, however, we have no reason to revise the conclusions reached by the previous stock status assessment.

## SUMMARY

1. The Salmon River (Langley) supports one of a group of B.C. coho stocks being monitored for responses to management actions by measuring
annual escapement, marine survival, harvest distribution and exploitation rate. This report documents the 1990 brood year results.
2. Coded wire tags (CWTs) and adipose fin clips (AFCs) were applied to emigrant smolts at fence traps in Salmon River and Coghlan Creek, the principal tributary, from April 16 to June 1, 1992. Tagged smolts were transported and released below a pumphouse at the river mouth.
3. A total of 28,141 coho smolts were released with CWTs and AFCs. Size averaged 91.5 mm nose-fork length and 7.8 g wet weight.
4. Adult spawners were enumerated by a markrecapture study from October 27, 1993 to January 21,1994 . Coho adults were captured using an electroshocker and marked with disk tags and opercular punches. Escapement was censused by the recovery of carcasses following spawning.
5. The 1993-1994 coho adult escapement was estimated from a tag application sample of 490, a recovery sample of 1,046 , and a recovery of 84 tags or secondary marks. The escapement was estimated at 5,913 adults, of which 3,169 were male, 2,744 were female and 1,184 had AFCs. Long term CWT loss was 8.8\%.
6. The proportion of the smolt release which returned to the spawning grounds was $3.8 \%$. The proportion was higher in Coghlan Creek than in Salmon River, and higher among late releases.
7. Most ( $97.8 \%$ ) of the adult escapement was age $3_{2}$. Adult POH length averaged 43.9 cm for females and 41.4 cm for males.
8. Spatial and temporal biases in the application and recovery samples were identified during this study; however, they were considered unlikely to have biased the escapement estimate.
9. Increased escapement was observed for the first time in the seven year study period; however, the reasons for the increase will not be known until the harvest data are available for analysis.

## ACKNOWLEDGEMENTS

The field work was conducted by $J$. Echols, E. Humphrey, R. Redden, A. Walter and

a. Incorrect sex identification during disk tag application
d. See Appendix 5 for reach descriptions.
b. Required ventilation at release.
e. Recovered without secondary mark.
c. Brulsed at release.
f. Lengths excluded form regressions.

Appendix 7a. Daily coho carcass recoveries, by reach, mark status and sex, in the Salmon River, 1993-1994.

|  | Not recorded | 0 | 0 | 0 | - |

a. Either a carcass with no head or the head was lost during processing.

Appendix 11. Spawning success in female coho carcasses recovered on the Salmon River system spawning grounds, 1993-1994.

| Mark status |  | Percent spawned |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 0\% | 50\% | 100\% | Weighted mean |
| Disk tag or | Number | 2 | 0 | 37 |  |
| secondary mark | Percent | 5.1\% | 0.0\% | 94.9\% | 94.9\% |
| Unmarked | Number | 3 | 2 | 150 |  |
|  | Percent | 1.9\% | 1.3\% | 96.8\% | 97.4\% |
| Total | Number | 5 | 2 | 187 |  |
|  | Percent | 2.6\% | 1.0\% | 96.4\% | 96.9\% |

[^0]:    a. Weighted by proportion of smolt migration in time periods.

[^1]:    a. Included in 'Total' column.
    b. Includes 1 disk tag without a secondary mark.

[^2]:    a. Totats inctude unageable samples.
