## Canadian Manuscript Report of Fisheries and Aquatic Sciences 2594

## Canadian Manuscript Report of Fisheries and Aquatic Sciences

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-900 in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551.

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport manuscrit canadien des sciences halieutiques et aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques ques qui constituent une contribution aux connaissances actuelles, mais qui traitent de problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports manuscrits sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annual des publications scientifiques et techniques du Ministère.

Les numéros 1 à 900 de cette série ont été publiés à titre de manuscrits (série biologique) de l'Office de biologie du Canada, et après le changement de la désignation de cet organisme par décret du Parlement, en 1937, ont été classés comme manuscrits (série biologique) de l'Office des recherches sur les pêcheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de rapports manuscrits de l'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

Les rapports manuscrits sont produits a l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

#### Abstract

Boyce, I. 2002. Enumeration of adult chum salmon, Oncorhynchus keta, in the Fishing Branch River, Yukon Territory, 1996. Can. Manuscr. Rep. Fish. Aquat. Sci. 2594: 33 p.

A total of 77,200 migrating adult chum salmon (Oncorhynchus keta) were enumerated at a weir on the Fishing Branch River from August 19 through October 22, 1996. The run was estimated to be $52.2 \%$ female ( $n=77,200$ ), $0.3 \%$ age $-3_{1}, 67.8 \%$ age $-4_{1}, 29.3 \%$ age $-5_{1}, 2.5 \%$ age$6_{1}$ and $0.1 \%$ age $7_{1}(\mathrm{n}=690)$. Fork length $(\mathrm{mm})$ averaged 694 for males ( $\mathrm{n}=854$ ) and 648 for females ( $n=836$ ). Sixty-three spaghetti tags were observed. Six tagged fish were captured. These fish had been marked at Rampart Rapids; average time in transit and migration rates were 27.8 days (std. dev. $=6.7$ ) and $53.3 \mathrm{~km} /$ day (std. dev. $=16.4$ ), respectively. In a sample of fish that drifted downstream onto the weir the estimated expenditure of milt/eggs averaged $80.1 \%$ for males ( $\mathrm{n}=74$, std. dev. $=19.4 \%$ ) and $84.3 \%$ for females ( $\mathrm{n}=76$, std. dev. $=19.4 \%$ ). Four chinook and 12 coho salmon were observed. Water temperature ranged from $7.5^{\circ} \mathrm{C}$ to $0.5^{\circ} \mathrm{C}$; level fluctuated by 9 cm .

## RÉSUMÉ

Boyce, I. 2002. Enumeration of adult chum salmon, Oncorhynchus keta, in the Fishing Branch River, Yukon Territory, 1996. Can. Manuscr. Rep. Fish. Aquat. Sci. 2594: 33 p.

Entre le 19 août et le 22 octobre 1996, on a dénombré un total de 77200 adultes de saumon kéta (Oncorhynchus keta) en migration à une pêcherie fixe installée sur la rivière Fishing Branch. On a estimé que la remonte se composait à $52,2 \%$ de femelles ( $n=77$ 200), dont $0,3 \%$ d'âge $3_{1}, 67,8 \%$ d'âge $4_{1}, 29,3 \%$ d'âge $5_{1}, 2,5 \%$ d'âge $6_{1}$ et $0,1 \%$ d'âge $7_{1}(\mathrm{n}=690)$. La longueur à la fourche ( mm ) était en moyenne de 694 pour les mâles ( $\mathrm{n}=854$ ) et de 648 pour les femelles ( $\mathrm{n}=836$ ). On a observé 63 étiquettes spaghetti. Six poissons marqués ont été capturés; ils avaient été marqués aux rapides Rampart; le temps moyen de transit et la vitesse de migration étaient respectivement de 27,8 jours (écart-type=6,7) et de $53,3 \mathrm{~km} /$ jour (écart-type=16,4). Dans un échantillon de poissons récupérés à la pêcherie alors qu'ils dérivaient vers l'aval, on a estimé l'émission moyenne d'œufs et de laitance à $80,1 \%$ pour les mâles ( $n=74$, écart-type $=19,4 \%$ ) et à $84,3 \%$ pour les femelles ( $n=76$, écart-type $=19,4 \%$ ). Quatre quinnats et douze cohos ont été observés. La température de l'eau allait de $7,5^{\circ} \mathrm{C}$ à $0,5^{\circ} \mathrm{C}$; le niveau de l'eau a fluctué de 9 cm .

### 1.0 INTRODUCTION

Chum salmon (Oncorhynchus keta) native to the south fork of the Fishing Branch River have been enumerated annually since 1971. From 1972 to 1975,1985 to 1989 , and 1991 to 1996 a weir was used; in other years, escapement was estimated using aerial counts (JTC 1996b). Field operations and administration for the enumeration program have been conducted by Fisheries and Oceans Canada (DFO) in co-operation with the Vuntut Gwitchin First Nation (VGFN).

The 1996 Fishing Branch River weir project supported the Upper Yukon River fall chum salmon mark-recapture project, a co-operative study involving the U.S. National Marine Fisheries Service (U.S. NMFS), the U.S. Fish and Wildlife Service (U.S. FWS), the Alaska Department of Fish and Game (ADF\&G) and DFO. The objectives of the project were to estimate the number of chum salmon migrating past Rampart, Alaska and to study the distribution of fall chum salmon stocks throughout the upper Yukon River drainage basin. In 1996, approximately 18,000 spaghetti tags were applied at Rampart Rapids, approximately 50 km downstream of the village of Rampart. Two fishwheels were used to capture the fish for tagging - one adjacent to each bank of the river. Different coloured tags were used to identify capture fishwheel (Gordon et al 1998).

### 1.1 OBJECTIVES

The specific objectives of the 1996 Fishing Branch chum enumeration program were as follows:

1. to enumerate, by species and sex, all adult salmon passing the weir site;
2. to assess age/ length composition and spawning success of the adult chum salmon passing the weir site;
3. to document hydrological conditions (temperature and level); and
4. to collect data related to the spaghetti-tagging project at Rampart; specifically, the number of tags observed.

### 1.2 WATERSHED DESCRIPTION

Located in the northern Yukon Territory, the south fork of the Fishing Branch River is a headwater tributary of the Porcupine River, itself a major tributary to the Yukon River. The Fishing Branch River flows northeast out of the Ogilvie Mountains, draining an area of
approximately 1700 square kilometres (NTS 116 J.K E 1/2, Department of Mines and Technical Surveys 1959). The south fork joins the north fork near Bear Cave Mountain and flows into the Miner River, a tributary of the upper Porcupine River (Figure 1). The spawning area on the Fishing Branch River is approximately $2,600 \mathrm{~km}$ from the Bering Sea (Bergstrom 1991).

Figure 1. Map of the weir site on the fishing branch river.

The terrain in the Fishing Branch River watershed includes rolling hills with elevations generally below 450 m with some mountains up to 1000 m . Muskeg often extends to the riverbank. Trees include black and white spruce, willow and birch. There are ponds and thermokarst basins in the region, but no lakes (Oswald and Senyk 1977).

The closest climatological station to the Fishing Branch River is in Old Crow, approximately 120 km to the north of the weir site. Temperatures recorded at the station during the period $1968-1990$ averaged $-9.3^{\circ} \mathrm{C}$ and ranged from $-59^{\circ} \mathrm{C}$ to $32^{\circ} \mathrm{C}$. The mean annual precipitation during this period was 239.5 mm . (Environment Canada files).

The main channel of the Fishing Branch River is clear, swift, and meandering with riffles, large exposed gravel bars and pools up to 2.5 m deep. The streambed is made up of large cobble ( $50-250 \mathrm{~mm}$ ) and medium cobble ( $2-50 \mathrm{~mm}$ ) (Bryan 1973). Side channels are slow and have fine granular sediment over medium cobble (Bruce 1975).

Stream discharge fluctuates greatly due to regional precipitation and the spring snowmelt. Flood-like conditions in the summer and fall after rainfall are not uncommon. Available flow measurements at the weir site range from 11.3 cubic metres per second in March 1972 (Steigenberger 1972) to 56.6 cubic metres per second in September 1972 (Elson 1975). A 15 km stretch of groundwater discharge in the headwaters of the south fork of the Fishing Branch River maintains open water in winter many kilometres downstream. The weir site is in the open water area.

### 1.3 FISHERIES RESOURCE OVERVIEW

### 1.3.1 Species Present

The south fork of the Fishing Branch River is a major spawning ground for fall chum salmon ${ }^{1}$. Estimates of escapement have ranged from 15,150 to 353,282 chum salmon (JTC 1996b and Elson 1976). Spawning occurs from September to November. The groundwater flow provides a habitat suitable for spawning adults, incubating eggs and rearing juveniles when temperatures in the region are well below freezing (Steigenberger 1972).

Coho salmon ( $O$. kisutch) spawn in the same area in October and November. Bryan (1973) reported that 150 coho juveniles were seined in a 300 square metre shallow riffle area of the Fishing Branch River in March 1972 and 12 were caught in a seine in May 1972. Low numbers of adult coho salmon have been enumerated at the weir. However, total escapements are unknown since the weir is removed before the coho migration is believed to be complete, because of weather conditions.

In July and August, chinook salmon ( $O$. tshawytscha) also spawn in the groundwater area (Steigenberger, et al. 1973). Low numbers of adult chinook have been observed at the weir and it has been suggested that the majority of the escapement each year occurs prior to weir installation. However, this was not supported by observations made in 1998 (Doehle 1999, Boyce and Wilson 2001).

Non-salmon species present in the area include: slimy sculpin (Cottus cognatus), round whitefish (Prosopium cylindraceum), Arctic grayling (Thymallus arcticus), and burbot (Lota). Northern pike (Esox lucius), humpback whitefish (Coregonus clupeaformis) and broad whitefish (Coregonus nasus) have also been noted at the weir site, and in the lower limits of the Fishing Branch River (Steigenberger et al. 1973).

[^0]
### 1.3.2 Non-Human Utilisation

Grizzly bears, wolves and eagles, among other mammals and birds are known to be supported in part by the salmon stocks of the Fishing Branch River.

In a 6.5 km reach located in the vicinity of the weir site, the grayling population has been estimated to be 9,000 fish (Bruce 1973). In that study, stomach content analyses showed that the grayling diet included chum eggs and alevins. Other fish species native to the Fishing Branch River are believed to prey upon chum salmon eggs, alevins, and fry.

### 1.3.3 Human Utilisation

Fishing Branch River salmon are harvested in Canada by the VGFN on the Porcupine River near Old Crow, and in Alaskan subsistence and commercial fisheries along the length of the Yukon River in the United States. They may also be intercepted in the United States groundfish trawl fisheries in the Bering Sea-Aleutian Islands area and the Gulf of Alaska, in purse seine and salmon gillnet fisheries in the "False Pass" area near the south Alaska Peninsula, and in coastal gillnet fisheries in Norton Sound. Until 1992, Fishing Branch River salmon may have been harvested in other off-shore fisheries, namely:

1. the Japanese high-seas mothership and land-based salmon gillnet fisheries;
2. the high-seas squid gillnet fisheries in the North Pacific Ocean of Japan; the Republic of Korea, and the Republic of China (Taiwan);
3. the foreign groundfish fisheries of the Bering Sea and Gulf of Alaska;
4. the joint-venture groundfish fisheries of the Bering Sea and Gulf of Alaska; and
5. the groundfish trawl fishery by many nations in the "Doughnut Hole" international waters area of the Bering Sea.

These fisheries harvested large numbers of salmon some of which were likely of Yukon River origin, and therefore potentially of Fishing Branch River origin. However, several of the offshore fisheries have been phased out by international agreements (JTC 1993c).

### 2.0 METHODS

### 2.1 WEIR LOCATION AND CONSTRUCTION

The weir was installed on the south fork of the Fishing Branch River approximately 31 km west of the Miner River confluence (Figure 1). The location has not varied since a weir was first installed on the Fishing Branch River in 1972. Approximate co-ordinates are $66^{\circ} 32^{\prime}$ north and $139^{\circ} 15^{\prime}$ west (NTS map reference $116 \mathrm{JK} 1: 50,000$ ).

Materials and methods used to construct the weir were similar to those used since 1985. Photographs of the structure are presented in Boyce 2001. Components included approximately 15 iron tripods, plywood/angle-iron stringers, electrical conduit, $\mathrm{Vexar}^{\mathrm{TM}}{ }^{\text {2 }}$ (plastic screening) and sandbags. A sampling chamber constructed from rebar, angle-iron stringers, and conduit was placed where flow was the greatest (close to the middle of the river). This formed the apex of the weir. Tripods were placed out at a slight angle downstream from the sampling chamber to each bank of the river. The distance between tripods was 3 m ( 10 ft .). Tripods were interconnected by pairs of horizontal stringers that were bolted approximately one quarter and three quarters of the way up from the bottom of the upstream leg of each tripod. Conduit inserted at $5 \mathrm{~cm}\left(2^{\prime \prime}\right)$ centres through the stringers provided the actual barrier to fish migration. Conduit was also inserted into the sampling chamber frame at the upstream end and sides. There was no gate at the downstream end of the chamber. Fish passage through the weir was made possible by removal of two or three pieces of conduit from the upstream end of the chamber. (This opening is hereafter referred to as the "gate".) A platform, supported by the weir itself and rebar driven into the river bottom, was placed by the side of the sampling chamber to permit enumeration and sampling.
$\mathrm{Vexar}^{\top \mathrm{M}}$ mesh was laid out along the lower portions of the conduit to further stabilise and seal the weir. Approximately 120 burlap bags filled with gravel were used to hold the Vexar ${ }^{\text {TM }}$ in place and help anchor the structure.

Lighting consisted of approximately fourteen floodlights (100 and 150 watt) strung across the weir and within the camp, to facilitate night counting and to provide safe conditions for personnel. A gasoline-fuelled generator was used as the power source.

Weir construction was completed on August 18 at 2300 hrs.

[^1]
### 2.2 ENUMERATION

### 2.2.1 Weir

Enumeration commenced three hours after weir installation was complete.
Migrants were counted at the upstream end of the sampling chamber as they swam through the open gate, or were manually transported over the closed gate using a dip-net. Approximately $2 \%$ of the run was handled in order to estimate its age and length composition. When practicable, tagged fish were captured and stripped of their tags (Appendix 5).

Generally fish passage occurred 24 hours per day. Exceptions to this occurred shortly after weir installation when few fish were present, occasionally just prior to sampling in order to allow fish to congregate in the sampling chamber, and when staff were occupied with other duties such as sampling carcasses. This amounted to a total of 117 hours over the course of the season (Appendix 1).

Enumeration ceased at midnight on October 22. Demobilisation commenced the following morning.

### 2.2.2 Aerial survey

There was no aerial survey in 1996 (see Section 4.0).

### 2.3 BIOLOGICAL SAMPLING

The chum salmon escapement was sampled in order to estimate age and length composition by sex. Fish were retrieved from the sampling chamber with a dip-net and placed in an aluminium tub containing river water. Using forceps, three scales were removed from the preferred area (located above the lateral line on an imaginary line extending from the posterior end of the dorsal fin to the anterior end of the anal fin). Fork length was measured to the nearest five mm using a flexible plastic tape measure. Sex was recorded. After sampling, fish were placed in an in-river recovery pen on the upstream side of the weir, from which they could exit freely.

A total of 1,690 live fish were sampled for age-length data. The target sample was 750 fish; this target was based on the number of samples required to characterise a population of approximately 100,000 fish having three age classes, with $95 \%$ confidence and $+/-5 \%$ precision (DFO files; from Cochran 1977). It was assumed that approximately $30 \%$ of the scales would be uninterpretable due to resorption. Protocol dictated that sampling be conducted in proportion to run timing; the unexpected abundance meant that the earlier part of the run was over-sampled.

Age (scale) samples were sub-sampled in proportion to run timing; only 798 samples were processed.

Measurements and age structures were also collected from carcasses of chum salmon that had drifted downstream onto the weir, either deceased or in a moribund state. Sex, post-orbital hypural $(\mathrm{POH})$ length, and fork length were recorded. Ten scales were removed from each fish. This exceeded the number removed from live samples since handling time was not a concern, and it was expected that scale resorption would be a greater problem. Pectoral fins, otoliths and vertebrae were also collected. The gonads in each carcass were examined in order to assess spawning success. The amount of reproductive material observed was expressed as a percentage of what was estimated to have been present prior to spawning. Pre-spawn fish were not examined for comparison purposes.

The primary purpose of the carcass sample was to augment the live fish sample. Bony structures assisted in the interpretation of scale patterns by providing insight on resorption rates. On sexually mature fish that have migrated large distances without feeding, bony structures provide more reliable age data than scales, since they do not appear to be subject to the same degree of resorption. The two length measurements were taken in order to allow inference of POH length on live fish. POH length is more difficult to measure than fork length on living fish; however it is often a more useful estimator of length since it is not influenced by the changes in morphology that chum salmon exhibit as they approach sexual maturity (primarily kype development). A total of 150 carcasses were sampled in 1996.

### 2.4 HYDROLOGICAL DATA

Water temperature and level was recorded every four hours, with some interruptions. Temperature $\left({ }^{\circ} \mathrm{C}\right)$ was taken from the platform adjacent to the sampling chamber using a handheld alcohol thermometer. The temperature within the top six inches of the water column was measured.

A staff gauge was positioned close to the south bank of the river approximately five metres downstream from the weir. Placement may have varied slightly from other years of the study. The function of the gauge, which was not zeroed or placed in the deepest section of the river, was to track water level fluctuation throughout the 1996 enumeration period.

### 2.5 AGE ANALYSIS AND DATA STORAGE

Scales, pectoral fins, otoliths, and vertebrae were sent to the Fish Ageing Lab at the DFO Pacific Biological Station in Nanaimo, B.C. for age analysis.

Raw data were transcribed into Microsoft ${ }^{8}$ Excel and stored at the DFO office in Whitehorse, Y.T.

### 3.0 RESULTS

### 3.1 ENUMERATION

### 3.1.1 Weir Count

A total of 77,200 adult chum salmon were observed passing the weir site in 1996 (Appendix 2).

The run appeared to have four major peaks, increasing in magnitude over time (Figure 2). The highest daily count, 4,988 fish, was recorded on September 19. The run mid-point fell on September 16. A late pulse of fish was observed on October 18.

Hourly counts are presented in Appendix 3.0 and Appendix 3.1. (The count recorded for a given hour represents the number of migrants observed from the beginning to the end of that hour). Figure 3 depicts diel run timing averaged over the course of the observed run. (The numbers of fish that passed through the weir at a specific time each day were summed and divided by the number of days.) Certain days were censored, specifically those on which fish passage was completely halted for more than one hour ${ }^{3}$ or there was a count of fewer than 500 fish. (Variability in diel run timing appeared to increase substantially on days with very low weir passage rates.) The average hourly counts suggest that 1800 hrs and 2000 hrs to midnight were the favoured times for fish passage. However, variability was high (Appendix 3.2).

The number of upstream migrants identified as female was $40,269(n=77,200)$, comprising $52.2 \%$ of the total count. The contribution of females increased over time, ranging from $39.0 \%(n=3,732)$ in statistical week (SW) 35 , to $66.9 \%(n=281)$ in SW 43 (Table 1).

Four chinook salmon and 12 coho salmon were observed migrating through the weir in 1996 (Appendix 4). The chinook were observed between August 20 and September 23, inclusive. Sex composition was not determined. One post-spawn female chinook was recovered on the upstream side of the weir on October 19. The coho were observed from October 8 to October 21, inclusive. One was female; the gender of the others was not determined. Whitefish and arctic grayling were also observed at the weir site.

### 3.1.2 Tag Data

A total of 63 spaghetti tags were observed at the weir (Appendix 5). Forty of these were yellow; the rest were white. Six tags were recovered; these had been applied at Rampart Rapids, Alaska. On average, 27.8 days elapsed ( $n=4$; std. dev. $=6.7$ ) between the tag application and tag

[^2]recovery events. This translates to an average migration rate of $53.3 \mathrm{~km} / \mathrm{day}^{4}$ (std. dev.=16.4) assuming that each fish resumed its migration immediately after tag application and was captured immediately upon arrival at the weir.

### 3.2 BIOLOGICAL SAMPLING

### 3.2.1 Live Fish

Sampling effort in relation to run timing is presented in Table 2.
Fork length measurements taken from live male and female chum salmon are presented in Table 3. Post-orbital hypural lengths are also presented; these are inferred from fork lengths using the formula developed by regression analysis of lengths obtained from carcasses. The fork lengths taken from males averaged 694 mm (std. dev. $=37 \mathrm{~mm} ; \mathrm{n}=854$ ). The fork lengths obtained from females averaged 648 mm , (std. dev. $=31 \mathrm{~mm} ; \mathrm{n}=836$ ). The POH lengths calculated for males averaged 543 mm (std. dev. $=25 \mathrm{~mm}$ ). For females, POH length averaged 528 mm (std. dev. $=21 \mathrm{~mm}$ ).

Of the 798 scale samples taken from live fish and sent to the morphology lab for processing, $690(86.5 \%)$ yielded complete age data. Of the remaining samples, 61 ( $7.6 \%$ of total) were resorbed, $17(2.1 \%)$ were regenerated and $30(3.8 \%)$ had been mounted incorrectly on the scale cards. Age data for each week were expanded by the weir count, with each sex treated separately (Table 4). The estimated age composition for the run was as follows: $0.3 \%$ age- $3_{1}$, $67.8 \%$ age $-4_{1}, 29.3 \%$ age $-5_{1}, 2.5 \%$ age $-6_{1}$, and $0.1 \%$ age $-7_{1}$. Data by SW are presented in Appendix 6.

### 3.2.2 Carcasses

Age, sex and length data collected from the carcasses of fish that drifted downstream to the weir are presented in Appendix 7. Estimates of the expenditure of eggs or milt in individual carcass samples were somewhat variable, averaging $80.1 \%$ (std. dev. $=19.4 \% ; \mathrm{n}=74$ ) for males and $84.3 \%$ (std. dev. $=19.4 \% ; n=76$ ) for females. Minimum values were $40 \%$ and $10 \%$ for males and females respectively.

Linear regression was used to determine the relationship between fork length and POH length. Males and females were treated separately. The relationship for each gender was significant at $\mathrm{p}_{\text {critical }}=0.05$. The equation developed for males was $a=0.68 b+69.8(\mathrm{df}=69$; $\mathrm{r}-$ square $=0.83$ ), where $a=$ fork length and $b=P O H$ length. Likewise, the equation developed for females was $a=0.68 b+86.8(\mathrm{df}=72$; r -square $=0.79)$.

[^3]
### 3.3 HYDROLOGICAL DATA

Water temperature readings are presented in Appendix 8. The range observed over the course of the season was $7.0^{\circ} \mathrm{C}$. The maximum temperature recorded was $7.5^{\circ} \mathrm{C}$ (August 31 ); the minimum was $0.5^{\circ} \mathrm{C}$ (October 22). Readings taken at 2000 hrs each day are presented in Figure 4.

The highest water level reading, 0.65 m , was taken on August 19 at 2000 hrs (Appendix 9). Levels do not reflect the absolute depth of the river as the gauge was not zeroed or placed in the deepest section of the river. The lowest reading, 0.56 m , was taken after October 18. Fluctuation was slight after the first few days of measurement. Figure 5 depicts the water level readings at 2000 hrs each day.

### 4.0 DISCUSSION

The Fishing Branch River weir count was $83 \%$ higher than the 1992-1995 ${ }^{5}$ average of approximately 42,000 chum salmon (Appendix 10). It was well below the lower end of the interim escapement objective range of 50,000 to 120,000 chum salmon, which was established through the Canada/U.S Yukon River Salmon Negotiations.

Figures 6 and 7 illustrate 1996 counts relative to those averaged over the recent cycle (1992-1995). The mid-point of the migration past the weir, September 16, was slightly earlier than the average mid-point, September 21. In contrast, the date on which the peak count was observed, September 19, was four days later than average. This average was strongly influenced by an unusually early peak in 1992 (September 6).

The contribution of females to the run (52\%) approximated the recent cycle average ( $54 \%$ ). The slight predominance of females that is observed at the weir most years might be a factor of gear selectivity in downstream fisheries. Males may be more susceptible to capture in gillnets because of their more pronounced snouts and teeth, particularly as they approach maturity (Milligan et al, 1986). Since most fish were not handled to determine gender, there was potential for error due to observer bias, poor visibility of individual fish because of high densities, low water clarity, and low light levels. Comparisons were made with the sex composition in the group of fish sampled for age and length data. All fish in this sample were closely inspected for gender. The pooled sample ( $n=1,690$ ) was $53 \%$ female, almost identical to the estimated run sex composition.

The fact that on average the carcasses sampled contained only small amounts of reproductive material (eggs/ milt) suggests that most of the population spawned successfully.

[^4]No aerial enumeration was conducted in 1996, since the relationship between aerial (helicopter) survey counts and weir counts has been quite variable. It appears that an aerial count is a poor substitute for a weir count. Prior to 1990, for years when there was no weir installed, aerial survey results were expanded by a factor of 2.71 to estimate escapement. In 1990, an expansion factor of 3.57 was used (JTC 1993c). Variability in aerial survey results can be due to differences in observer efficiency, water depth, clarity, and spawner density, run timing, and environmental factors. The density of spawners, their colouration, and the low light levels often experienced in September/ October make aerial enumeration of Fishing Branch River chum salmon particularly challenging.

It was expected pre-season that an average number of Fishing Branch River chum salmon would return from the ocean to the mouth of the Yukon River in 1996. The expectation was based on an assumed productivity of 2.5 returns per spawner ( $\mathrm{r} / \mathrm{s}$ ) for the principle brood years (1991 and 1992, respectively), and an expected return age composition of $71 \%$ age-four and $27 \%$ age-five. The 1996 forecast was for a return (i.e. run size) of 67,000 fish. In comparison, the run size was estimated to have averaged approximately 60,000 chum salmon from 1992-1995 ${ }^{6}$ (JTC 1996a).

The harvest of 3,025 chum salmon by the VGFN in the vicinity of Old Crow was close to the 1992-1995 average of approximately 2,900 fish. The U.S. harvest of Fishing Branch River chum salmon, estimated using the footnoted assumptions, was 25,420 fish (DFO files). The number of Fishing Branch River chum (U.S. and Canadian harvest, plus escapement) that returned to the mouth of the Yukon River in 1996 is therefore estimated to have been 105,645 fish, significantly greater than the pre-season projection. The harvest rate is estimated at $27 \%$.

### 5.0 RECOMMENDATIONS

The weir should continue to be operated annually as it serves as the only index of chum salmon escapement in the Canadian portion of the Porcupine sub-basin of the Yukon River in Canada. The Fishing Branch River chum salmon stock is of substantial socio-economic value to the Vuntut Gwitchin First Nation. The international importance of the Fishing Branch River chum stock has also been recognised, and stock rebuilding options have been discussed (JTC 1993b).

[^5]
### 6.0 ACKNOWLEDGEMENTS

Marty Strachan, Derek Able-Chitze and Isaac Thomas of the VGFN conducted the project fieldwork. Pam Vust and Lesia Hnatiw assisted with data processing. Sandy Johnston provided comments on a draft of this report. Sean Stark assisted with proofreading. Personnel in the Fish Ageing Lab at the Pacific Biological Station in Nanaimo, including Shayne MacLellan and Darlene Gillespie, provided fish ages.

Days on which passage of fish was completely halted for more than one hour are not included.
(a) only days on which more than 500 fish were counted are included.
(b) only days on which fewer than 500 fish were counted are included.

(a) kilometres per day.
(b) assumes that each fish resumed its migration immediately after tag application and was captured immediately upon arrival at the weir.

Appendix 6. Age composition of Fishing Branch River chum salmon by statistical week, 1996.

Appendix 10. Annual counts of Fishing Branch River salmon, 1971-1996.

| Year | Chum | a,b | Chinook |
| :---: | :---: | :---: | :---: | :---: | :---: |${ }^{h}$ Coho ${ }^{h}{ }^{h}$

a Total escapement estimated using weir to aerial survey expansion factor of 2.72 , unless otherwise indicated.

- Aerial survey count unless otherwise indicated.
c Weir installed on September 22. Estimate consists of a weir count of 17,190 after September 22, and a tagging passage estimate of 17,935 prior to weir installation.
- Weir count.
e Initial aerial survey count was doubled before applying the weir/aerial expansion factor of 2.72 since only half of the spawning area was surveyed.
1 Weir was not operated. Although only 7,541 chum salmon were counted on a single survey flown October 26, a population estimate of approximately 27,000 fish was made through date of survey, based upon historic average aerial-to-weir expansion of $28 \%$. Actual population of spawners was reported by DFO as between 30,000-40,000 fish considering aerial survey timing.
${ }^{9}$ Incomplete count due to late installation and/or early removal of project or high water events.
${ }^{n}$ Weir counts unless otherwise indicated.

[^0]:    ${ }^{1}$ Chum salmon in the Yukon River system can be separated into two major groups: fall (or autumn), and summer. Fall chum can be distinguished from summer chum as adults by: (1) later entrance into freshwater, (2) less developed reproductive systems at the time of entry into freshwater, (3) a later spawning period, (4) larger size, and (5) greater fecundity (Groot and Margolis 1991).

[^1]:    ${ }^{2}$ Mention of trade names does not constitute endorsement.

[^2]:    ${ }^{3}$ i.e. when the gate was closed and no fish were manually transferred over the gate.

[^3]:    ${ }^{4}$ Rampart Rapids and the Fishing Branch River weir are approximately 1,176 and 2,575 kilometres, respectively, from the mouth of the Yukon River (Bergstrom et al 1991).

[^4]:    ${ }^{5}$ This period was chosen because it represents the most recent cycle; the predominant age of spawning Fishing Branch River chum salmon is four years.

[^5]:    ${ }^{6}$ The stock size is used here to mean the number of adult fish returning to the Yukon River from marine areas. Run size calculations are based on the following assumptions: (a) $30 \%$ of the U.S. catch is composed of Canadian-origin fish; (b) the U.S. harvests Canadian stocks in the same ratio as: upper Yukon River border escapement-to-Porcupine River border escapement; and (c) the Porcupine River border escapement consists of the Old Crow catch plus the Fishing Branch River escapement. A key assumption is that the Fishing Branch River upstream of the weir site is the only chum spawning area in the Canadian portion of the Porcupine River drainage.
