#### Abstract

Hardie, D. C., D. A. Nagtegaal, J. Sturhahn, and K. Hein. 2002. Strait of Georgia and Northern Vancouver Island sport fishery creel survey statistics for salmon and groundfish, 2000. Can. Manuscr. Rep. Fish. Aquat. Sci. 2608: 112 p.

This report documents the 2000 catch and effort estimates for the Strait of Georgia and Northern Vancouver Island sport fishery creel surveys. Catch and effort statistics for the Strait of Georgia and Northern Vancouver Island tidal sport fishery are presented for each month, Statistical Area and by individual species. Strait of Georgia creel survey data collection began in 1980 and continues today. Historical data are presented from as far back as 1960 and comparisons are made between the current and these historical data to determine trends in catch and effort.

The 2000 Strait of Georgia statistics for Statistical Areas 13, 14, 15, 16, 17, 18, 19, 28 and 29 , were derived from 13,480 fishing interviews and 47 aerial surveys. For the entire year 2000 anglers conducted an estimated 170,798 boat trips and kept 32,750 chinook, 4,678 coho, 2,558 chum, 9,771 pink, 6,367 sockeye salmon, as well as 543 halibut, 6,127 lingcod and 54,881 rockfish. Catch and effort for 2000 shows a continuing downward trend, effort has decreased $1.8 \%(161,316$ to 158,404$)$ and total salmon catch decreased $31 \%(71,614$ to 49,752 ) from 1999. Historically effort has dropped from a high of 664,517 boat trips in 1988 and chinook catch has dropped from a high of 369,445 in 1984. Total salmon catch per boat trip has decreased from 0.47 in 1999 to 0.33 in 2000. Chinook catch also decreased $35 \%$ from 43,559 in 1999 to 28,226 for the same period in 2000. Among salmon examined for adipose-clips, $6.8 \%$ of chinook and $86 \%$ of coho had adipose fin clips. The chinook catch consisted of $2.2 \%$ age 2 fish, $56.6 \%$ age 3 fish, $35.0 \%$ age 4 and $6.2 \%$ age 5. The length frequency distributions of the chinook and coho are also given.

The 2000 Northern Vancouver Island statistics for Statistical Area 12, were derived from 1,862 fishing interviews and 10 aerial surveys. Anglers conducted an estimated 15,934 boat trips and kept 4,628 chinook, 125 coho, 103 chum, 23,519 pink, 744 sockeye salmon, as well as 1,524 halibut, 1,066 lingcod and 8,959 rockfish. The effort for 2000 showed an decrease of $51 \%$ from 32,443 boat trips in 1999. Total salmon catch also decreased $44 \%$ from 52,227 in 1999. Total salmon catch per boat trip has increased from 1.60 in 1999 to 1.83 in 2000. Among chinook salmon examined for adipose-clips, $2.1 \%$ had adipose fin clips. The age composition of chinook catch consisted of $28.0 \%$ age 3 fish, $57.1 \%$ age 4 and $14.8 \%$ age 5 and older fish. The length frequency distributions of the chinook and coho are also given.

## RÉSUMÉ

Hardie, D. C., D. A. Nagtegaal, J. Sturhahn, and K. Hein. 2002. Strait of Georgia and Northern Vancouver Island sport fishery creel survey statistics for salmon and groundfish, 2000. Can. Manuscr. Rep. Fish. Aquat. Sci. 2608: 112 p.

Ce rapport présente les captures et l'effort de pêche estimés à partir des relevés de la pêche sportive pour le détroit de Géorgie et le nord de l'île de Vancouver en 2000. Les statistiques sur la pêche sportive dans les eaux à marée de ces deux régions sont présentées par mois, par zone statistique et par espèce. La collecte de ces données pour le détroit de Géorgie a débuté en 1980 et se poursuit encore. Des données remontant jusqu'à 1960 sont présentées et comparées aux données actuelles pour déterminer l'évolution des captures et de l'effort de pêche.

Les statistiques de l'an 2000 pour les zones statistiques $13,14,15,16,17,18,19$, 28 et 29 du détroit de Géorgie ont été obtenues à partir de 13480 entrevues de pêcheurs et de 47 relevés aériens. On estime qu'au cours de l'année 2000, les pêcheurs sportifs ont effectué 170798 sorties en bateau et ont gardé 32750 saumons quinnats, 4678 saumons cohos, 2558 saumons kétas, 9771 saumons roses, 6367 saumons rouges, 543 flétans, 6127 morues-lingues et 54881 sébastes. Les données de captures et d'effort de pêche en 2000 montrent que la tendance à la baisse se poursuit : par rapport aux chiffres de 1999, l'effort de pêche a fléchi de $1,8 \%$ (de 161316 à 158404 ) et les prises totales de saumon ont diminué de $31 \%$ (de 71614 à 49752 ). L'effort de pêche avait atteint un sommet de 664517 sorties en bateau en 1988, tandis que le nombre de saumons quinnats capturés annuellement avait atteint un maximum de 369445 en 1984. Les prises totales de saumon par sortie en bateau ont baissé de 0,47 en 1999 à 0,33 en 2000. Les prises de saumon quinnat ont diminué de $35 \%$, soit de 43559 en 1999 à 28226 pour la même période en 2000. Quant aux saumons examinés pour voir s'ils étaient marqués, $6,8 \%$ des saumons quinnats et $86 \%$ des saumons cohos avaient la nageoire adipeuse coupée. Les prises de saumon quinnat était constituées de 2,2 \% de poissons de 2 ans, de $56,6 \%$ de poissons de 3 ans, de $35,0 \%$ de poissons de 4 ans et de $6,2 \%$ de poissons de 5 ans. La distribution de la fréquence des longueurs est également présentée pour les saumons quinnat et coho.

Les statistiques de l'an 2000 pour la zone statistique 12, qui couvre le nord de l'île de Vancouver, ont été obtenues à partir de 1862 entrevues de pêcheurs et de 10 relevés aériens. On estime qu'au cours de l'année 2000, les pêcheurs à la ligne ont effectué 15934 sorties en bateau et ont gardé 4628 saumons quinnats, 125 saumons cohos, 103 saumons kétas, 23519 saumons roses, 744 saumons rouges, 1524 flétans, 1066 morues-lingues et 8959 sébastes. En 2000, l'effort de pêche a baissé de $51 \%$ par rapport aux 32443 sorties en bateau effectuées en 1999. Les prises de saumon totales ont également baissé, de $44 \%$ par rapport aux 52227 saumons capturés en 1999. Par contre, les prises totales de saumon par sortie en bateau ont augmenté de 1,60 en 1999 à 1,83 en
2000. Des saumons quinnats examinés pour voir s'ils étaient marqués, $2,1 \%$ avaient la nageoire adipeuse coupée. Les prises de saumon quinnat était constituées de $28,0 \%$ de poissons de 3 ans, de $57,1 \%$ de poissons de 4 ans et de $14,8 \%$ de poissons de 5 ans ou plus. La distribution de la fréquence des longueurs est également présentée pour les saumons quinnat et coho.

## PART 1

STRAIT OF GEORGIA

## INTRODUCTION

Part 1 of this report documents the 2000 catch and effort statistics for the Strait of Georgia sport fishery and presents the methodology for collecting these data. Data are presented in tables and graphs with catch and effort dating back to 1960. The 2000 catch and effort are displayed in tables by month, Statistical Area and species. Graphs showing historical trends and comparisons in catch and effort for 93-97 average, 1998, 1999 and 2000 are also provided. The 2000 report is one of a series of annual reports documenting the activities of the creel survey and providing official Strait of Georgia tidal sport fishery catch statistics. A list of previous reports in this series may be found in Appendix A. In this report all tables, figures and appendices are located at the end of text.

## BACKGROUND

The Strait of Georgia fishery supports one of the most valuable recreational fisheries in British Columbia. Coded-wire tag recoveries indicate these fish stocks consist primarily of Fraser River, Puget Sound and East Coast Vancouver Island streams. There has been evidence of declining stocks since the 1970's (Argue et al. 1983). Various groups (Commercial, First Nation and Recreational) on both sides of the border depend on these stocks. There is also evidence from declining marine survival rates of salmon stocks (Cross et al. 1991; Beamish et al. 1994), that marine environmental factors may be involved.

The creel survey study area (Fig. 1, Appendix B) comprises over $5,900 \mathrm{~km}^{2}$ of water surface area and has in excess of $2,400 \mathrm{~km}$ of shoreline. From its southern end near Victoria, the area extends about 290 km northwest to Campbell River and at its greatest width is about 32 km wide. Two major population centres, Vancouver and Victoria, and many smaller centres such as Nanaimo and Campbell River are located within the study area. Over 500 boat launch ramps, marinas and public wharves as well as thousands of private boat launching facilities provide access.

The recreational fishery is active throughout the year but over $85 \%$ of the effort occurs in the summer months of May to September (Collicutt and Shardlow 1993). The most sought after species in the Strait of Georgia recreational fishery are the chinook (Oncorhynchus tshawytscha) and coho ( $O$. kisutch) salmon, but in recent years significant fisheries directed at pink (O. gorbuscha), sockeye (O. nerka), rockfish (Sebastes) and halibut (Hippoglossus stenolepis) have developed in certain areas.

The size of vessel, methods of fishing and terminal tackle vary widely depending on location and time of year. Vessels range from 4 m car-top boats to yachts more than 17 m in length, although most boats would be in the 5 m to 8 m range. Popular fishing methods include trolling, mooching, bucktailing and stripcasting.

Over the past three decades the recreational fishery in this area has undergone dramatic changes. Prior to 1960, the numbers of chinook and coho taken by the
commercial troll fleet was almost double that taken by sport fishermen. During the 1980's however, the situation reversed with the sport fishery taking more than triple the commercial harvest of chinook and coho. The recreational fishery is still the primary harvester of chinook and coho in the Strait of Georgia. Effort in the recreational fishery has fluctuated from about 200,000 boat trips in 1960 to peaks of 769,000 in 1980 and 600,000 in 1988 to an all time low of 162,000 boat trips in 1998.

The Creel Survey for 2000 ran from April to September in all Statistical Areas of the Strait of Georgia. Additional Creel Survey coverage was provided to Statistical Area 19 ( 12 months) and Areas 13 and 14 for October. For historical comparisons, the catch and effort statistics for April to September are used. The entire catch and effort statistics for the year 2000 are provided in the tables, figures and appendices.

The 2000 fishery showed a $2 \%$ decrease in effort to 158,000 boat trips from 161,000 in 1999. The chinook catch climbed through the 1960's with a peak in the mid 1970's of over 400,000 pieces and a second peak of 330,000 pieces in 1984. A steady decline has occurred since, to a low of 20,000 pieces in 1998. The chinook catch showed a significant improvement of $108 \%$ to 44,000 pieces in 1999. The 2000 catch however has declined once again by $35 \%$ to 28,000 pieces. Although annual coho catches have varied widely, an increase from about 200,000 pieces in 1960 to over one million pieces in 1988 was recorded. A gradual decline from 1988 levels to 98,000 pieces in 1997 has followed the general decline of stocks. The 1999 coho catch was an all time low of 315 pieces, this was due, however, to a majority of areas being closed to coho retention. The coho catch for 2000 has improved dramatically by $1200 \%$ to 4,200 pieces, primarily from retention of adipose-clipped only fisheries in selected areas.

From 1956 to 1976, estimates of catch and effort in the sport fishery published by the Department of Fisheries and Oceans (DFO) were based on subjective assessments completed by Fishery Officers and on small-scale creel surveys. The general lack of statistical rigor and consistency associated with these methods of catch estimation as well as the rapid growth of the recreational fishery led to the initiation of the Strait of Georgia Creel Survey Pilot Program in 1980 (DPA 1982). The survey has been run continuously (with minor interruptions) since then. Although many details such as sampling locations and times are regularly updated to reflect changes in the fishery, the basic design of the survey remains similar to the pilot project conducted in 1980.

Creel survey data are used for a variety of management and reporting purposes. Catch and effort information is also used by local people (both inside and outside DFO) to monitor the fishery in their area. In addition, creel survey information is used to predict the effect of regulation changes and to measure the success of conservation actions imposed. The adipose clip information collected during the survey is supplied to the Mark Recovery Program (Kuhn et al. 1988) and used in combination with other data for exploitation rate, marine survival and stock distribution analyses.

## OBJECTIVES

The specific objectives of the 2000 Strait of Georgia creel survey were:

1. To estimate the sport angler effort, catches and releases of chinook, coho, chum, pink, sockeye salmon, halibut, lingcod, rockfish and other finfish by month for Statistical Areas 13 through 19, 28 and 29.
2. To estimate the catch rate for adipose-clipped chinook and coho in the sport fishery.
3. To estimate the age composition and mean length-at-age for chinook, and the length frequency for chinook and coho.

## METHODS

## STUDY DESIGN

The design of the Strait of Georgia Creel Survey conducted in 2000 was similar to that used by DPA Consulting Ltd. (1982) with some modifications to the data analysed, sampling intensity, flight routes and data processing. It is comprised of two independent surveys: angler interviews and aerial overflights. Angler interviews provide data on sport fishing catch per unit effort (CPUE) and daily activity patterns. Aerial overflights provide estimates of the total sport fishing effort in the study area at the time of the aerial survey. These data are combined to provide monthly estimates of total sport fishing effort and total catch of salmon and groundfish in the sport fishery. In its simplest form, the estimated total catch is calculated by multiplying the estimated total effort by CPUE.

The fishery was stratified according to the following criteria:
1.- Month. The survey operated from April through to and including September for the entire geographic area. Statistical Area 19 received 12 months of survey coverage for 2000 and Statistical Areas 13 and 14 also received additional coverage for October.
2. Geographic area. Catch and effort estimates were produced for Statistical Areas 13 through 19, 28 and 29 (Fig. 1, Appendix B).
3. Day type. Weekend and mid-week days were considered independently because sport fishing activity is known to differ for the two types of days.
4. Time of day. Sampling shifts (one shift is a set number of consecutive hours of interviewing anglers at one site by one creel surveyor) were conducted during set time periods. From April to October sampling was conducted during either an
early shift (approximately 0700 to 1500 hours) or a late day shift (approximately 1500 to 2300 hours).
5. Guided versus unguided anglers. Certain sites are known to have considerable guided fishing effort. Unpublished data from previous surveys in this series indicate that the CPUE from guided boats differs markedly from unguided boats. Guided vs. unguided, was documented by the interviewer, however, at this time the catch estimate program does not generate catch and effort estimates differently for the two parties.

In each region, various landing sites were chosen as locations for surveyors to conduct interviews. Site selection was based on four criteria: representativeness, traffic volume, site accessibility and adequate observation points. Discussions with local fishers, marina operators and Fisheries Officers and data from previous surveys were used to choose sites that were representative of the local sport fishing activity (i.e. sites which were used by a wide cross-section of anglers). Sites with expected traffic volumes of more than 15 boats per day in the summer were considered as possible sampling locations. Expected traffic volumes for sites were compiled from previous surveys or from discussions with marina operators or local Fisheries Officers.

Site accessibility refers to whether an interviewer can easily reach a site by car or ferry during the defined shift hours. Only sites with good accessibility were selected. As a result, landing sites on most of the islands in the Strait of Georgia were excluded from the survey. This was not expected to be a major factor, however, since most of the fishing occurs from accessible sites. The final criterion, adequate observation points, was essential for interviewers to obtain an accurate count of all boats returning to a landing site. At some large marinas, two sampling sites were identified if it was impossible to see all boats returning.

Allocation of sampling effort among months followed the same general pattern as fishing effort, that is, more effort was allocated during the summer when fishing effort is at its highest. Allocation of sampling effort among regions (groups of Statistical Areas) also followed fishing effort patterns. Within each month, each chosen site was allocated between 6 and 10 shifts. These shifts were divided equally among weekend and midweek days and early and late daily time periods.

Fisheries and Oceans Canada conducted data collection, preliminary processing and conducted the estimation of catch and effort statistics.

## DATA COLLECTION

## Angler Interviews

Surveyors were stationed at access points for scheduled shifts to interview anglers as they returned from fishing. The number of boats returning to a site during a shift as
well as the number of interviews attempted and completed were recorded on a tally sheet. For each boating party landing, the following information was recorded on an interview form (Fig. 2):

1. Total number of licensed anglers in the boat.
2. Time of landing.
3. Whether the party had been sport fishing and whether guided or not guided.
4. Residency of anglers.
5. Time of departure and length of trip.
6. Time during which fishing lines were in the water.
7. Average number of lines in the water.
8. Catch Summary: -Total number and species of kept and released fish for each of the sub-Statistical Areas (possible to record for three separate sub-Statistical Areas).
-Number of hours spent fishing, type of fishing conducted and primary fishing location in each sub-Statistical Area.
9. Coded wire tag information for chinook and coho.
10. Number of hours directed at each species.
11. Loss of catch to seals or sea lions.
12. Shellfish catch summary (New for 2000)

Interviewers trained in fish identification inspected each boating party's catch. Landed chinook and coho were checked for a missing adipose fin, which indicates the presence of a coded-wire tag, embedded in the fish's nose cartilage. In addition, scale samples for age determination and measurements of nose-fork length were taken during every sampling shift. Five scales were removed from the INPFC (International North Pacific Fisheries Commission) preferred area of each biosampled chinook (Mosher 1968).

In 2000, interviews were conducted each month at a maximum of 38 of the 50 designated landing sites (boat ramps, marinas, or resorts, Fig. 1) representative of the sport fishing activity in the survey area. Targets of desired precision and number of surveyors available dictated the number of sites selected in each area. For each area - day type - work block stratum, sampling shifts at a site were chosen on a near random basis from the total number of shifts available. For definition of the above terms (day type, work block, shift) see Appendix C.

## Aerial Overflights and vessel counts

April through to and including October aerial surveys were conducted by J. O. Thomas in conjunction with Transport Canada from airplanes travelling along predefined routes (Fig. 3). This allowed observers to count vessels actively sport fishing throughout the Strait of Georgia. Planes flew at an altitude of 150-210 m (500-700 feet) to facilitate a broad range of vision and still allow easy identification of vessel type. Each plane carried one observer; the observer counted sport fishing boats in the flight
path. The counts of sport fishing boats for the Victoria (Statistical Area 19) creel survey for January, February, March, November and December were conducted by D. F. O. The counts were conducted from a boat travelling along a predefined route through Area 19.

The flight and boat path and time of departure were designed to cover major concentrations of sport fishing activity at peak periods. To maximise precision, the observers in the airplanes and boat avoided times during which fishing effort was rapidly changing. The number of overflights and boat runs each month was governed by budget constraints, targets of desired precision and by the expected number of interviews from a given number of sampling shifts (English et al. 1986). The days for overflights and boat runs during a month were randomly selected for each day type (weekday and weekend).

## DATA ANALYSIS

Data analysis included calculation of catch and effort statistics, calulation of variance of total fishing effort and catch, estimation of marked chinook and coho salmon, estimation of age and length composition of chinook catch and length frequency distribution of coho. See Appendix C for established methods and equations used to analyse the above data.

To provide more accurate catch and effort estimates the computer analysis program was altered in 2000.

The initial creel survey catch estimate analysis program was based on the landing site. A mean catch per effort (CPUE) estimate for a landing group was based on data from several nearby landing sites. The CPUE estimates were then matched to the subarea using information on the sub-areas fished by anglers returning to the landing sites within the landing group.

The new analysis program uses sub-area specific CPUE estimates to compute catch estimates for each sub-area. That is the actual catch and effort from fishing events with in the statistical sub-area are use to generate the estimates. The combination of subarea CPUE estimates and sub-area effort estimates is a more accurate and simpler analysis approach (English 2000).

An additional change to the analysis program is the removal of factors used to weight the CPUE estimates for each landing site to account for the portion of boat trips interviewed and the number of interview shifts per work block. The number of boat trips that include fishing activity for a specific sub-area, the similarity in CPUE between adjacent sub-areas, and obtaining a large representative sample from each of the major fishing areas are the most important factors of the new method. Some formulas used to estimate the standard errors for CPUE and total catch have changed (Appendix C, formulas $1,2,3$ and 4).

## RESULTS AND DISCUSSION

## DISTRIBUTION OF SAMPLING EFFORT

A total of 19,159 interviews, of which 13,480 involved actively fishing anglers, and 83 overflights were conducted in 2000 (Table 1). The monthly distribution of interviews generally reflected the monthly distribution of fishing effort (number of boat trips, Table 3,Fig. 4). The total interviews represent $11.2 \%$ of the estimated total fishing effort for the entire study area (170,798 boat trips, Table 3). The interviews involving actively fishing anglers represent $7.9 \%$ of the total fishing effort and ranged in each Statistical Area from lows of $0.9 \%$ in Area 15 and $3.8 \%$ in Area 18 to highs of $9.7 \%$ in Area 17 and $10.4 \%$ in Area 19 (Tables 1 and 4). For the 2000 Creel Survey Statistical Areas $13,14,15,16,17,28$ and 29 received coverage for April through to and including September while Statistical Area 19 received 12 months of coverage, and Statistical Areas 13 and 14 received additional coverage through October (Table 1).

## SPORT FISHING EFFORT AND CATCH

For comparisons to 1999 catch and effort estimates only the estimates from April to September will be discussed. The total 2000 Strait of Georgia sport fishing catch and effort statistics are summarised for each species by month (Tables 3, 5, 7, 9 and 11) and by Statistical Area (Tables 4, 6, 8, 10 and 12). Fishing effort and catch statistics by species are presented for each combination of month and Statistical Area (Appendices D1 to D-12).

Anglers made 158,404 boat trips during 2000; this is a $1.8 \%$ decrease in effort from $1999(161,316)$. The estimated effort in 2000 shows a continuing downward trend in angler effort (Fig. 5). The fishing effort followed the same general seasonal pattern as seen in previous years where effort levels climbed steadily from April, peaked in August and declined in September and October (Table 3, Fig. 6).

The total finfish sport catch in the Strait of Georgia was estimated at 142,932 pieces (including steelhead and cutthroat trout) and consisted of $35 \%$ salmon, $27 \%$ groundfish and $38 \%$ rockfish (Tables 3, 5, 7 and 11). Anglers released an additional 87,662 salmon of mixed species (Tables 3, Appendix D-8).

The major regulation change, which affected the 2000 sport fishery were the large area closures on the West Coast of Vancouver Island, July 15 and August 1, 2000. The closure areas changed from no fishing outside of one mile, to a conservation corridor for Areas 21 to 25 with no fishing from the surfline to one nautical mile offshore. This closure was in effect to conserve West Coast Vancouver chinook stocks. Regulation changes introduced in 1998 and which remain in affect are:

1. Only barbless hooks were to be used when fishing for salmon, throughout the coast.
2. Non-retention of coho in all B. C. tidal and non- tidal waters was enforced with the exceptions of a few selected terminal adipose-clipped (hatchery) fisheries such as the mouth of the Capilano River (Statistical Area 28), a portion of Sechelt Inlet (Area 16), the Big Qualicum River (Area 14) and Sooke (Area 19). Coho daily limits were two with a possession limit of four; minimum size was 41 cm .

General regulations included a minimum size limit for chinook of 62 cm , with a daily limit of two, possession of four, and an annual limit of 15 for the Strait of Georgia (Cape Sutil to Cadboro Bay). In a portion of Statistical Area 19 (Cadboro Bay to Sheringham Pt.), the minimum size limit for chinook was 45 cm , with a daily limit of two, possession of four, and an annual limit of 20. See Appendix $G$ for a historical synopsis of regulation changes.

## Salmon

Salmon sport catches for the Strait of Georgia in 2000 totalled 49,752 pieces (April to September) and 56,130 for the entire creel period (Tables 1 and 3). The catch consisted of $57 \%$ chinook, $9 \%$ coho, $2 \%$ chum, $20 \%$ pink and $13 \%$ sockeye.

In 2000, anglers kept 28,226 chinook (Tables 3 and 4), compared to 43,559 in 1999 and 20,536 in 1998 (Table 2, Fig. 5). Although the 1999 catch showed a significant increase from 1998, the 2000 Chinook catch decreased $35 \%$ from 1999. The 2000 monthly chinook catches rose steadily through June and July and peaked in August (Table 3, Fig. 7). The seasonal (April to September) average catch efficiency for chinook decreased from 0.27 in 1999 to 0.18 fish per boat trip overall and peaked in the summer months at 0.24 fish per boat trip (Table 13, Fig. 8). Catch patterns were similar to those in recent years. The catch success rate for salmon in Statistical Area 19 for January to March was 0.65 and for November to December it was 0.59 .

The spatial distribution of chinook catch followed a similar pattern to previous years. The highest catches were taken in Area 13 (36\% of total), Area 19 (23\%), and Area 14 (19\%) (Table 4, Appendix D-2, Fig. 9). The chinook catch per unit effort (CPUE) was 0.27 for Area 13, 0.24 for Area 14 and 0.27 for Area 15 (Table 4, Appendix D-2). Peak catches occurred during June, July and August.

A large increase in coho catch occurred in 2000. The total coho catch was 4,294 pieces (Tables 3 and 4, Appendix D-3). Monthly coho catches peaked in August, but were consistently high through the summer months (Table 3, Fig. 10 and 11). The increase in coho catch was due to and increase of terminal (adipose-clipped) retention fishieries in Statistical Areas 13, 14, 19, 28 and 29. Of the coho catch, $64 \%$ occurred in Area 28.

In 2000, Strait of Georgia anglers caught 1,099 chum (Table 3, Fig. 12), with almost the entire catch coming from Area 13 (Table 4). Also 9,761 pink (Table 3 and 4,

Fig. 13) of which $97 \%$ came from Area 13 and 6,367 sockeye (Table 3, Fig. 14), where the highest catches also were from Area 13 ( $80 \%$; Table 4).

The average number of salmon caught during each boat trip in 2000 decreased from 0.44 in 1999 to 0.31 .

| Year | CPUE |
| :--- | :--- |
| 1990 | 1.46 |
| 1991 | 1.18 |
| 1992 | 1.59 |
| 1993 | 2.30 |
| 1994 | 0.89 |
| 1995 | 1.07 |
| 1996 | 0.81 |
| 1997 | 1.09 |
| 1998 | 0.24 |
| 1999 | 0.44 |
| 2000 | 0.31 |

In 2000 , Areas $13(24 \%)$ and $19(22 \%)$ showed the highest effort expended with a total salmon CPUE of 0.71 and 0.22 , respectively (Table 4, Fig. 15). Area 13 recorded the highest CPUE at 0.71 fish per trip. July and August were the most successful summer months at 0.39 and 0.45 salmon per trip. Statistical Area 19 had a CPUE of 0.65 for January to March and 0.60 for November and December (Table 13).

There were also significant numbers of salmon caught and released in 2000. A total of 52,576 chinook and 35,086 coho were released. Area 14 recorded the greatest number of salmon hooked and released followed by Area 13 (Table 4, Appendix D-8).

## Groundfish

While salmon accounted for the majority of the total finfish sport catch historically, the 2000 Strait of Georgia catch consisted of 92,180 groundfish, which made up $65 \%$ of the overall catch (Tables 3 and 4).

Numbers within the "other" catch category declined dramatically, from 13,793 in 1999 to only 23 in 2000. The decline in numbers is attributed to more accurate species catch data in the field and estimates generated by the analysis program. The category of "other" catch has more accurately been placed into the total groundfish catch category.

Comparing catch estimate data from 1995 when the creel program was not as species specific to today's creel program catch estimates for 2000, total groundfish catch has increased $100 \%$ while "other" catch has decreased $99 \%$. Angler effort when compared for the same period, shows a decline of $48 \%$ and total rockfish catch also shows a $50 \%$ decline. The species composition of the groundfish catch, based on the Tables 5, 7 and 11 data, is as follows:

| Groundfish | Catch | \% of Total <br> Groundfish <br> Catch | Major <br> Catch <br> Area |
| :--- | ---: | :--- | :--- |
| Species |  | 496 | $0.5 \%$ |
| Halibut (Hippoglossus stenolepis) | 6,116 | $6 \%$ | 19 |
| Lingcod (Ophiodon elongatus) | 53,320 | $59 \%$ | 16 |
| Rockfish (Sebastes spp.) | 32,229 | $35 \%$ | 16 |
| Other Groundfish | 19 |  |  |
| Other Finfish | 92,180 | $100 \%$ |  |
| Total |  |  |  |

The majority of the groundfish catch was taken in the summer months, reflecting the high fishing effort in the summer (Tables 5, 7, 9 and 11; Fig. 6). Catch by Statistical Area for rockfish was highest in Area 16 ( $40 \%$ of total; Table 8). Lingcod were caught in greatest numbers in Area 16 ( $20 \%$ of total; Table 6), while the largest halibut catch came from Area 19 ( $91 \%$ of total; Table 6). Area 16 produced the largest catch of other groundfish (Table 12, Appendix G.).

Rockfish species were identified for the entire survey area in 2000, catch and release estimates were generated for nine species (Tables 7, 8, 9 and 10). The major catches are shown below. The "other" rockfish category consists of canary (Sebastes pinniger), china (S. nebulosus), redstripe (S. proriger), tiger (S. nigrocinctus), yellowtail (S. flavidus) and unidentified species.

| Rockfish <br> Species | Catch | \% of Total <br> Rockfish <br> Catch | Major <br> Catch <br> Area |
| :--- | ---: | :--- | :--- |
| Black (Sebastes melanops) | 237 | $0.4 \%$ | 19 |
| Copper (Sebastes caurinus) | 10,613 | $20 \%$ | 19 |
| Quillback (Sebastes maliger) | 32,455 | $61 \%$ | 16 |
| Yelloweye (Sebastes ruberrimus) | 4,372 | $8 \%$ | 16 |
| Other (Sebastes spp.) | 5,643 | $11 \%$ |  |
| Total | 53,320 |  |  |

Along with the 53,320 rockfish harvested in 2000, an additional 30,335 rockfish were released (Table 9). An additional catch of 40,261 shellfish were harvested (Table 11). The shellfish catch consisted of $60 \%$ oysters, $21 \%$ prawns, $13 \%$ clams and $6 \%$ crabs.

The CPUE for rockfish (Table 13, Fig. 16 and 17) was relatively constant throughout the creel survey period and averaged 0.33 fish per boat trip, while the CPUE for halibut was 0.003 and lingcod was 0.04 fish per boat trip (Table 13). The CPUE for all non-salmon species and for total finfish during 2000 was 0.58 and 0.90 , respectively (Table 13).

## BIOLOGICAL DATA

## Percentage and Catch of Adipose-clipped Chinook and Coho

In 2000, 2,517 chinook and 266 coho were examined for adipose-clips. Tables 14 and 16 show for chinook and coho respectively, the number of clips observed and the total fish inspected by month and region. The data were presented by Region since some Statistical Areas had insufficient numbers of fish examined for clips in some months, and those data were included with other Areas. Three Regions were defined: the Northern Gulf represented by Areas 13-16; the South Gulf represented by Areas 17, 18, 28 and 29 and the Victoria region represented by Area 19.

Among chinook examined for adipose-clips, $6.8 \%$ had clips. The observed proportion of chinook adipose-clips was $9.5 \%$ for Victoria region, $8.3 \%$ for South Gulf and $3.3 \%$ for the North Gulf (Table 14). Among coho examined, $86 \%$ had adipose clips. There was a large increase in coho catch in 2000 primarily from adipose-clipped only fisheries in select terminal areas, the high percent (86\%) of adipose-clips reflect the fishery. Monthly catch estimates of adipose-clipped chinook and coho are shown by Region in Tables 15 and 17.

From the Strait of Georgia fishery, a total of 525 chinook with adipose-clips were returned to the head recovery program for coded-wire tag (CWT) extraction and decoding. The CWT data show that the main contributing rivers from the United States were the Wallace River (70), Cascade River from Marblemount hatchery (38) and Kendall Creek (30; Table 18). Canada's main contributing rivers were the Nanaimo and Cowichan Rivers both at 34 recovered CWTs, the Chemainus River (31), Puntledge (25), Chehalis (21) and the Shuswap (19; Table 18).

## Catch-At-Age for Chinook

During 2000, 2,662 chinook were sampled for length, 909 of these chinook were also sampled for age analysis. Of this total, 767 fish were found to have accurate ages ( 142 samples lost to regenerated scales, marine annuli, etc.). Table 19 shows the monthly number and percent age composition of chinook sampled for age. All ages shown in this report represent the saltwater age. The age data are summarised graphically in Figure 18. The monthly age proportions were applied to the estimated monthly chinook catches to provide a breakdown by age group (Table 20).

In 2000, the chinook sport catch in the Strait of Georgia consisted primarily of age 3 fish ( $56.6 \%$ ), followed by age 4 fish ( $35.0 \%$ ), age 5 fish ( $6.2 \%$ ) and age 2 fish (2.2\%). The age composition and catch at age shifts from age 4 chinook (Jan to May) to age 3 chinook for the remainder of the year (Table 19, 20 and Figure 18).

| \% Age Composition of Chinook |  |  |  |  | Reference |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Catch Year | 2 | 3 | 4 | 5+ |  |
| 1983 | 57.1 | 25.5 | 14.2 | 3.1 | Shardlow et al. (1989a). |
| 1984 | 21.6 | 67.3 | 9.4 | 1.7 | Shardlow and Collicutt (1989a) |
| 1985 | 6.6 | 70.8 | 20.6 | 2.0 | Shardlow and Collicutt (1989b) |
| 1986 | 10.9 | 44.9 | 40.4 | 3.8 | Shardlow and Collicutt (1989c) |
| 1987 | 7.8 | 62.1 | 25.0 | 5.2 | Shardlow and Collicutt (1989d) |
| 1988 | 26.4 | 35.3 | 35.4 | 2.8 | Shardlow and Collicutt (1989e) |
| 1989 | 3.1 | 83.3 | 10.5 | 3.1 | Collicutt and Shardlow (1990) |
| 1990 | 4.0 | 37.0 | 53.0 | 6.0 | Hardie et al. 1999 |
| 1991 | 2.0 | 67.0 | 25.0 | 6.0 | Hardie et al. 1999 |
| 1992 | 7.0 | 58.0 | 28.0 | 7.0 | Hardie et al. 1999 |
| 1993 | 1.0 | 69.0 | 26.0 | 4.0 | Hardie et al. 1999 |
| 1994 | 2.0 | 50.0 | 40.0 | 8.0 | Hardie et al. 1999 |
| 1995 | 2.0 | 62.0 | 29.0 | 7.0 | Hardie et al. 1999 |
| 1996 | 1.0 | 70.0 | 26.0 | 3.0 | Hardie et al. 1999 |
| 1997 | 0.0 | 66.0 | 29.0 | 5.0 | Hardie et al. 1999 |

| 1999 | 0.3 | 73.4 | 21.4 | 4.9 | Hardie et al. 2001 |
| 2000 | 2.2 | 56.6 | 35.0 | 6.2 | * |

*Calculated from this report's yearly catch estimates

## Mean Length-At-Age for Chinook

Table 21 shows the monthly mean nose-fork length at age for the 767 chinook for which both length and age data were available. Figure 19 shows the length frequency distribution for all the measured chinook. The overall mean length for age 3 fish was 666.8 mm and age 4 fish was 736.9 mm (Table 21). The largest salmon sampled were two 107 cm chinook at Painters Marina (Area 13).

As shown below, there was a minimal increase in the percentage of sub-legal size chinook ( 45 cm in the Victoria area and 62 cm in the Strait of Georgia). This percentage (number of under size chinook divided by the total chinook sampled for the area) has dropped and remained low since it's highest level in 1989 when the 62 cm size limit was implemented.

| Sub-legal Chinook |  |  |  |
| :---: | :---: | :---: | :--- |
| Year | Victoria | Strait of Georgia | Reference |
| 1989 | $2 \%$ | $20 \%$ | Collicutt and Shardlow, 1990 |
| 1990 | 0.01 | $10 \%$ | Collicutt and Shardlow, 1992 |
| 1991 | $<1 \%$ | $7 \%$ | Collicutt and Shardlow, 1993 |
| 1992 | 0.02 | $2 \%$ | Hardie et al. 1999 |
| 1993 | $1 \%$ | $2 \%$ | Hardie et al. 1999 |
| 1994 | $0 \%$ | $2 \%$ | Hardie et al. 1999 |
| 1995 | $0 \%$ | $3 \%$ | Hardie et al. 1999 |
| 1996 | $0 \%$ | $1 \%$ | Hardie et al. 1999 |
| 1997 | $0 \%$ | $2 \%$ | Hardie et al. 1999 |
| 1998 | $1 \%$ | $6 \%$ | Hardie et al. 1999 |
| 1999 | $0 \%$ | $<1 \%$ | Hardie et al. 2001 |
| 2000 | $1 \%$ | $2 \%$ | This report |

## Length Frequency Distribution for Coho

Figure 20 shows the length frequency distribution for the 186 coho sampled in 2000. The mean size of coho in 2000 was 53.2 cm , which is a decrease in coho size from 1999; however 1999 had the lowest number of coho caught and biosampled in the history of the Strait of Georgia creel survey. In the 1989 report (Collicutt and Shardlow 1990), an overall decline from 1986 to 1989 in the size of landed coho was noted. A similar size reduction trend appeared to be occurring once again in 1996 to 1998, as shown below:

Coho mean annual length

| Year | Mean Length | Sample Size |
| :---: | :---: | :---: |
| 1986 | 53.4 | 5354 |
| 1987 | 50.5 | 4997 |
| 1988 | 50.0 | 13000 |
| 1989 | 49.6 | 6883 |
| 1990 | 51.4 | 8959 |
| 1991 | 54.2 | 2281 |
| 1992 | 53.2 | 1960292 to 97 Unpublished reports |
| 1993 | 51.0 | 22203 |
| 1994 | 53.7 | 5890 |
| 1995 | 56.3 | 1672 |
| 1996 | 53.0 | 2257 |
| 1997 | 49.7 | 1710 |
| 1998 | 49.0 | 60 Hardie et al. 1999 |
| 1999 | 58.7 | 51 Hardie et al. 20001 |
| 2000 | 53.2 | 186 This report |

## SUMMARY

A sport fishery creel survey was conducted in the Strait of Georgia in 2000 to estimate the catches of all the important recreational finfish species and the total sport fishing boat trips. In the report, data are presented by both month and Statistical Areas. Comparisons are made to previous data to determine trends in catch and effort. From the catch and effort estimates, CPUE could be calculated. These data also provide estimates of the number of chinook and coho salmon with adipose fin clips. Also the age composition of chinook and the length frequency distributions of chinook and coho are shown.

Fishing effort had dropped $76 \%$ from a high of 664,517 boat trips in 1988 to a low of 162,296 in 1998. The 2000 season has shown a minor decrease of $1.8 \%$ in effort from 1999 to 158,404 boat trips. Total salmon catch decreased $31 \%$ from 71,614 to 49,752 and chinook catch also decreased from 43,558 in 1999 to 28,226 in 2000. Total salmon CPUE decreased from 0.44 in 1999 to 0.31 in 2000.

For the entire year 2000 creel survey period (April to October plus an entire 12 months for Statistical Area 19), sport fishers made an estimated 170,798 boat trips in the Strait of Georgia. A total of 19,159 boating parties, of which 13,480 were actively fishing, were interviewed at a monthly maximum of 35 landing sites in the Strait of Georgia Creel Survey area. This sampling represents approximately $11.2 \%$ of the total number of boat trips conducted by sport fishers in the Strait of Georgia in 2000. A total of 47 overflights were also conducted to take "snapshot" counts of fishing effort.

Sport fishers in the Strait of Georgia landed an estimated total yearly finfish catch of 150,803 pieces of which $37 \%$ were salmon and $63 \%$ were groundfish. The 56,130 landed salmon consisted of 32,750 chinook, 4,678 coho, 2,558 chum, 9,771 pink salmon and 6,367 sockeye salmon. Anglers released an additional 148,224 salmon of mixed species. The 94,673 landed groundfish consisted of 543 halibut, 6,127 lingcod, 54,881 rockfish and 165 other finfish

During the creel comparison period of April to September, Sport fishers in the Strait of Georgia landed an estimated total finfish catch of 141,932 pieces. The 49,752 landed salmon consisted of 28,226 chinook, 4,294 coho, 1,099 chum, 9,761 pink salmon and 6,367 sockeye salmon. Anglers released an additional 136,661 salmon of mixed species. The 92,180 landed groundfish consisted of 496 halibut, 6,116 lingcod, 53,320 rockfish and 19 other finfish

Among salmon examined for adipose-clips, $6.8 \%$ of chinook and $86 \%$ of coho had adipose-clips. The majority of chinook sport catches in 2000 consisted of age 3 fish ( $56.6 \%$ ), followed by age 4 fish ( $35.0 \%$ ), age 5 fish ( $6.2 \%$ ) and age 2 fish ( $2.2 \%$ ). Of the total chinook measured in $2000,1 \%$ were sub-legal in size. The mean yearly size of coho was 53.2 cm .

## PART 2

NORTHERN VANCOUVER ISLAND

## INTRODUCTION

Part 2 of this report documents the 2000 catch and effort statistics for the Northern Vancouver Island sport fishery. The Northern Vancouver Island access point creel survey follows the methodology of the Strait of Georgia creel survey for objectives, study design, data collection and data analysis. The following text in Objectives and Methods contain only the differences between the two creel surveys. A list of previous reports in this series may be found in Appendix A. In this report all tables, figures and appendices are located at the end of the text.

## BACKGROUND

The study area is located on the north-eastern coast of Vancouver Island (Fig. 21), consisting of Queen Charlotte and Johnstone Straits. The area is approximately 80 km wide by 110 km long, the creel survey study area was divided into 5 sub areas, 12A to 12E. The major fishing areas include Gordon Channel, Hardy Bay, Broughton Strait, Blackfish Sound, Baronet Passage, Knight Inlet, Tribune Channel, and Sutlej Channel. Statistical Sub Area 12D was not covered in 2000 due to the cost of an isolated access point and extended float plane over flights for boat counts. In 1999, 12D contained only $1.8 \%$ of the total effort for Area 12 and $1.5 \%$ of the total salmon catch (Hardie et al. 2001).

The 2000 creel survey ran for July and August. The most sought after species in the Northern Vancouver Island recreational fishery were the chinook (Oncorhynchus tshawytscha) and coho (O. kisutch) salmon, but with the closure of coho (1998), pink salmon ( $O$. gorbuscha) has replaced coho as a primary target species. Significant fisheries are also directed at sockeye (O. nerka), rockfish (Sebastes spp.) and halibut (Hippoglossus stenolepis).

The 2000 creel survey showed a decrease in estimated fishing effort of $51 \%$. Fishing effort of 32,443 boat trips in July and August 1999 decreased to 15,934 boat trips in 2000 for the same period. The average aerial count of boats actively fishing in August 1999 was 304 and in 2000 the count was 154 . The catches also reflect the decrease in fishing effort, 4,628 chinook, 23,519 pink salmon and 1,524 halibut were caught and an additional 9,626 released coho (Table 22). The 1999 creel survey estimated (July and August only) 7,259 chinook, 42,398 pink, 6,117 halibut and 22,604 released coho (Hardie et al.2001).

## OBJECTIVES

The objectives of the 2000 Northern Vancouver Island creel survey are contained in Part 1 Strait of Georgia objectives.

## METHODS

## STUDY DESIGN

The design of the 2000 Northern Vancouver Island Creel Survey was similar to that used for the 2000 Strait of Georgia Creel Survey, with some modifications to the data analysed, sampling intensity, flight routes and data processing.

The fishery was stratified according to the following criteria:

1. Month. The survey operated for July and August.
2. Geographic area. Catch and effort estimates were produced for statistical subareas 12A, 12B, 12C and 12E (Fig. 21).
3. Day type. Weekend and mid-week days were considered independently because sport fishing activity is known to differ for the two types of days.
4. Time of day. Sampling shifts (one shift is a set number of consecutive hours of interviewing anglers at one site by one creel surveyor) were conducted during set time periods. From June to September sampling was conducted during either an early shift (approximately 0700 to 1500 hours) or a late day shift (approximately 1500 to 2300 hours).
5. Guided versus unguided anglers. Certain sites are known to have primarily guided fishing effort. Unpublished data from previous surveys in this series confirm that the CPUE from guided boats differs markedly from unguided boats. Effort was made to document guided vs. unguided; however the catch estimate program has no allowances for guided versus non-guided.

Allocation of sampling effort among months followed the same general pattern as fishing effort (Fig. 22), that is, more effort was allocated during August when fishing effort is at its highest. Shifts were divided equally among weekend and mid-week days and early and late daily time periods.
D.F.O. conducted data collection, data entry, preliminary processing and generated estimations of the catch and effort statistics.

## DATA COLLECTION

## Angler Interviews

Surveyors were stationed at access points for scheduled shifts to interview anglers as they returned from fishing. For each boating party landing, the following questions were asked and information was recorded (Fig. 2).

In 2000, interviews were conducted each month at six sites, Echo Bay, Telegraph Cove, Alder Bay, the public ramp and the Quarterdeck Marina in Port Hardy and the Port McNeill ramp. For each area - day type - work block stratum, sampling shifts at a site were chosen on a near random basis from the total number of shifts available. For definition of the above terms (day type, work block, shift) see Appendix C.

Two main sources of potential bias may exist for this survey: non-representative sampling and analytical method. All of the high volume access points were identified and sampled through this survey to minimise the potential of non-representative sampling bias. Some active remote resorts (Farewell Harbour Resort, Double Bay Resort) in the Blackfish Sound area were not sampled for logistical reasons, however, the fishery in this area was represented through data collected at Telegraph Cove and Alder Bay sites. Potential bias occurs through analytical methodology when access point data cannot be highly associated with a specific sub-area (or sub-area group). For this survey access point data and sub-areas were associated using mapping analysis which indicated a very high degree of association for each site sub-area used minimising the potential for bias from this source. Fishing interviews from landings to the Quarterdeck Marina and public ramp in Port Hardy showed that $100 \%$ of the fishing activity occurred in sub-area 12A. Landings at Telegraph Cove showed $63 \%$ activity in sub-area 12 C and $32 \%$ activity in sub-area 12B. Fishing activity in Alder Bay was split with $57 \%$ in sub-area 12C and $41 \%$ in sub-area 12B. Port McNeill showed $69 \%$ fishing activity from sub-area 12B and 24\% in sub-area 12C. Sub-area 12E showed $84 \%$ of the fishing activity for Echo Bay.

## Aerial Overflights

Aerial surveys, conducted from airplanes travelling along a pre-defined 440 km route (Fig. 23), allowed observers to count vessels actively sport fishing throughout the Northern Vancouver Island. During the creel survey period 11 flights were conducted in 2000.

## DATA ANALYSIS

Methods and equations are contained in Appendix C.

## RESULTS AND DISCUSSION

## DISTRIBUTION OF SAMPLING EFFORT

A total of 2,052 interviews, of which 1,861 involved actively fishing anglers, and 11 overflights were conducted in 2000 . The monthly distribution of interviews generally reflected the monthly distribution of fishing effort (Table 23, Fig. 22). The total interviews represent $12.9 \%$ of the estimated total fishing effort (15,934 boat trips) for the
entire study area (Table 22). The interviews involving actively fishing anglers represent $11.7 \%$ of the total fishing effort.

## SPORT FISHING EFFORT AND CATCH

The 2000 Northern Vancouver Island sport fishing catch and effort statistics are summarised for each species by month (Tables 23, 25, 27, 29 and 31) and by statistical area (Tables 24, 26, 28, 30, 32). Appendix I and J give catch and effort by month and statistical sub-area.

Angler effort decreased in 2000 by $51 \%$ from 32,443 boat trips in 1999, to 15,934 boat trips in 2000. The August 2000 aerial boat counts which aid in the creel survey estimation program also decreased by $50 \%$ when compared to the August 1999 counts.

The total finfish sport catch in the Northern Vancouver Island was estimated at 44,845 pieces, including steelhead and cutthroat trout (Table 22) and consisted of $65 \%$ salmon and $35 \%$ groundfish. Anglers released an additional 14,530 chinook and coho salmon.

The major regulation change, which affected the 2000 sport fishery was the large area closures on the West Coast of Vancouver Island, July 15 and August 1, 2000. The closure areas changed from no fishing outside of one mile, to a conservation corridor for Areas 21 to 25 with no fishing from the surfline to one nautical mile offshore. This closure was in effect to conserve west Coast Vancouver chinook stocks. Regulation changes introduced in 1998 and which remain in affect are:

1. Only barbless hooks were to be used when fishing for salmon, throughout the coast.
2. Non-retention of coho in all B. C. tidal and non- tidal waters was enforced with the exceptions of a few selected terminal fisheries such as the mouth of the Capilano River (Statistical Area 28), a portion of Sechelt Inlet (Area 16), the Big Qualicum River (Area 14) and Sooke (Area 19). Coho daily limits were two with a possession limit of four; minimum size was 41 cm .

General regulations included a minimum size limit for chinook of 62 cm , with a daily limit of two, possession of four, and an annual limit of 15 for the Strait of Georgia (Cape Sutil to Cadboro Bay). In a portion of Statistical Area 19 (Cadboro Bay to Sheringham Pt.), the minimum size limit for chinook was 45 cm , with a daily limit of two, possession of four, and an annual limit of 20. See appendix F for a historical synopsis of regulation changes.

## Salmon

Salmon sport catches for the Northern Vancouver Island decreased 44\% from 52,227 in 1999 to 29,172 pieces in 2000 (Table 22). The catch consisted of $16 \%$ chinook, $81 \%$ pink and $3 \%$ sockeye salmon.

In 2000, anglers kept 4,628 chinook, 103 chum, 23,519 pink and 744 sockeye salmon (Tables 23 and 24, and Fig. 25), coho remained closed to retention. The average catch efficiency varied, chinook at 0.29 , chum 0.01 , pink 1.48 and sockeye at 0.05 (Table 33). The average boat trip caught 1.83 salmon, as compared to 1.60 in 1999. August was the peak month for salmon fishing with a CPUE of 2.07 (Table 33, Figures 24 and 25).

The fishing effort was evenly distributed through Statistical Area 12 in 2000, SubArea 12 C had $31 \%$ of angler effort, Sub-Area 12 A had $30 \%$, 12B had $28 \%$ and the remaining $10 \%$ was in Sub-Area 12E (Table 24). Sub-Area 12C contained $53 \%$ of the total salmon catch and 12B and 12 A contained $21 \%$ and $20 \%$ respectively (Table 24). Appendix I shows salmon catch and effort by month and sub-area.

The non-retention of coho for the 2000 sport fishing season continues to alter the catch estimates. Previously a significant coho fishery occurred in the Northern Vancouver Island with 25,873 retained in 1993 (access point survey April to the end of August). In 2000, anglers released 9,626 coho as compared to 22,604 coho in 1999 and 27,247 coho in 1998. For the first time since the closure of the coho retention fishery, pink salmon released $(12,606)$ was greater than the number of released coho $(9,626$; Tables 23 and 24).

## Groundfish

The 2000 Northern Vancouver Island catch consisted of 15,673 groundfish, which made up $35 \%$ of the overall catch. The species composition of the groundfish catch, based on the Tables 25 and 27 data, is shown below. The category "other" groundfish consists of starry flounder (Platichthys stellatus), rock sole (Lepidopsetta bilineata), dogfish (Squalus acanthias), cabezon (Scorpaenichthys marmoratus), greenling (Hexagrammos spp.) and other unidentfied sole and groundfish.

| Groundfish Species | Catch | \% of Total Groundfish Catch | Major <br> Catch <br> Area |
| :---: | :---: | :---: | :---: |
| Halibut (Hippoglossus stenolepis) | 1,524 | 10\% | 12B |
| Lingcod (Ophiodon elongatus) | 1,066 | 7\% | 12B |
| Other Groundfish | 4,124 | 26\% | 12B |
| Rockfish (Sebastes spp.) | 8,959 | 57\% | 12B |
|  | 15,673 |  |  |

The groundfish catch was evenly distributed between July and August (Tables 25 and 27). Catch by Statistical Sub-Area for all groundfish was highest in 12B (Tables 26 and 28). Appendix J shows groundfish catch and effort by month and Sub-Area.

Rockfish species were identified for the entire survey area in 2000, catch and release estimates were generated for nine species (Tables 27, 28, 29 and 30). The major catches are shown below. The "other" rockfish category consists of canary (Sebastes pinniger), china (S. nebulosus), redstripe (S. proriger), tiger ( $S$. nigrocinctus) and unidentified species.

| Rockfish Species | Catch | \% of Total <br> Rockfish <br> Catch | Major <br> Catch <br> Area |
| :---: | :---: | :---: | :---: |
| Black | 1,232 | 13.8\% | 12A |
| Copper | 733 | 8.2\% | 12B |
| Quillback | 4,351 | 48.6\% | 12B |
| Yelloweye | 1,486 | 16.6\% | 12B |
| Other | 1,157 | 12.9\% | 12B |
|  | 8,959 |  |  |

The CPUE for rockfish was relatively constant throughout the creel survey period and averaged 0.56 , while the CPUE for halibut was 0.10 and lingcod was 0.07 (Table 33). The CPUE for all total finfish during was 2.81 (Table 33).

## BIOLOGICAL DATA

## Percentage and Catch of Adipose-clipped Chinook and Coho

In 2000, 524 chinook were examined for adipose-clips (Table 34). Among chinook examined, $2.1 \%$ had adipose clips. A total catch of 101 clipped chinook was estimated for Northern Vancouver Island in 2000 (Table 35).

## Catch-At-Age for Chinook

During 2000, 392 chinook biological samples were collected for age and length analysis. Table 36 shows the monthly number and percent age composition of chinook sampled for age. All ages shown in this report represent the saltwater age. The age data are summarised graphically in Figure 26. The monthly age percentages were applied to the estimated monthly chinook catches to provide a breakdown by age group (Table 37).

In 2000, the chinook sport catch in Northern Vancouver Island consisted primarily of age 4 fish (57.1\%), followed by age 3 fish ( $28.0 \%$ ) and age $5+(14.3 \%)$ (Table 37). Age 4 fish were the dominant component of the catch throughout the year with age 3 fish primarily making up the remainder of the catch (Tables 36 and 37).

## Mean Length-At-Age for Chinook

Table 38 shows the monthly mean nose-fork length at age for the 392 chinook for which both length and age data were available. Figure 27 shows the length frequency distribution for all the measured chinook. The overall mean length for age 3 fish was 74.0 cm , age 4 fish was 83.0 cm and age 5 fish was 95.1 cm (Table 38). Two age 6 fish were sampled in 2000, their average size was 100.0 cm (Table 38).

## SUMMARY

A sport fishery creel survey was conducted in the Northern Vancouver Island in 2000 to estimate the catches of all the important recreational finfish species and the total sport fishing boat trips. In the report, data are presented by both month and Statistical Sub-Area. From the catch and effort estimates CPUE could be calculated.

The downward trend in fishing effort and catch of the main target species was evident again in 2000. Fishing effort decreased $51 \%$ from 32,443 (1999) to 15,934 (2000). Total salmon catch also decreased by $44 \%$ from 52,227 (1999) to 29,172 in 2000.

Sport fishers made an estimated 15,934 boat trips in the Northern Vancouver Island. A total of 2,052 boating parties, of which 1,862 were actively fishing, were interviewed at six landing sites in the Northern Vancouver Island creel survey area. This sampling represents approximately $12.9 \%$ of the total number of boat trips conducted by sport fishers in the Northern Vancouver Island. A total of 11 overflights were also conducted during the creel survey period.

Sport fishers in the Northern Vancouver Island landed an estimated total finfish catch of 44,845 pieces of which $65 \%$ were salmon and $35 \%$ were groundfish. The 29,172 landed salmon consisted of 4,628 chinook, 103 chum, 23,519 pink salmon and 744 sockeye salmon. Anglers released an additional 4,904 chinook and 9,626 coho salmon. CPUE averaged 1.83 for salmon (all species), 0.42 for groundfish and 2.81 for total finfish. The 15,673 landed groundfish consisted of 1,524 halibut, 1,066 lingcod, 8,959 rockfish and 4,124 other finfish.

Among chinook salmon examined $2.1 \%$ had adipose clips. The majority of chinook sport catches in 2000 consisted of age 4 fish ( $57.1 \%$ ), followed by age 3 fish ( $28.0 \%$ ) and age $5+(14.8 \%)$. The mean annual length of chinook at age 3 was 74.0 cm , age 4 was 83.0 cm and age 5 was 95.1 cm .

## ACKNOWLEDGMENTS

We would like to thank the staff of J. O. Thomas and Associates, particularly Doug Tallman for co-ordinating and providing the Strait of Georgia overflight information, and to Leslie Fell for co-ordinating the decoding of the coded-wire tag recoveries. Thanks to the Pisces Research crew who assisted with the Northern Vancouver Island overflights. Thanks to the ageing lab at the Pacific Biological Station for scale analysis and compiling the age data. Special thanks also to Ted Carter for his assistance on various parts of this report. Also we would like to thank the private marina and boat ramp owners for their valuable assistance and co-operation and to the many thousands of anglers who voluntarily participated in the survey.

*Catch and effort estimates: 1983 to 1992 from prior annual reports (see Appendix A), 1993 to 1997 from unpublished creel survey data.
** A zero in a species column indicates that no catch estimates were generated for that species for that year.
***Other catch has dropped because of more accurate catch recording in the creel survey and more inclusive species catch estimates, other catch has been more accurately put into total groundfish, rockfish and shellfish categories.

## APPENDIX B. STRAIT OF GEORGIA CREEL SURVEY STUDY AREA.

The Strait of Georgia Creel Survey study area and landing site locations used in 1998 are shown in Appendix B-2. The study area includes those waters of Juan de Fuca Strait and the Strait of Georgia bounded in the south by a line from Sheringham Pt. on Vancouver Island due south to an intersection with the International Boundary and along the International Boundary to the B.C, Mainland coast at Blaine (Boundary Bay) and in the northern by the following 3 boundary lines:

1) Discovery Passage from Granite Pt. on Quadra Island to the stream mouth west of Moriarty Pt. on Vancouver Island.
2) Okisollo Channel from Granite Pt. on Quadra Island due northern to Sonora Island.
3) Cordero Channel from Burnt Bluff on the mainland $214^{\circ}$ passing west of Dent Island to Sonora Island.

The area for which the Strait of Georgia Creel Survey statistics apply includes the above listed administrative area with the exception of the following areas:

1) Bute Inlet above a line from Lawrence Pt. running across the inlet. This area coincides with management units 13-21 and 13-22.
2) Waters of Pryce Channel, Waddington Channel, Pendrell Sound, Homfray Channel and Toba Inlet bounded by a line drawn from Horace Head on East Redonda Island at the south end of Waddington Channel to the northern point of Roscoe Bay on West Redonda Island and a line drawn within Homfray Channel from Price Pt. on the eastern shore of the channel by a line drawn from George Head at the easterly entrance of Ramsay Arm to Sutil Pt. on Cortes Island.
3) Hotham Sound above a line drawn from Elephant Pt. on the western shore of the Sound to the southern point of Granville Bay on the eastern shore of the Sound.
4) Jervis Inlet above a line drawn within Prince of Whales Reach from the mouth of Treat Creek on the east shore across the Reach to the Summit (1625') at the head of Goliath Bay.
5) Sechelt Inlet including Narrows Inlet and Salmon Inlet above a line drawn within Skookumchuck Narrows from the "dog-leg" point south-east of the Egmont Pt. $224^{\circ}$ across the Narrows to Sechelt Peninsula.

# APPENDIX C. METHODS AND EQUATIONS USED IN ANALYSIS OF CATCH AND EFFORT STATISTICS FOR THE STRAIT OF GEORGIA AND NORTHERN VANCOUVER ISLAND SPORT FISHERY CREEL SURVEY. 

Description of terms, variables and subscripts used in this report.

## DESCRIPTION OF TERMS

Shift/Stint
a single day. i.e. one
Work block - Represents one of four possible periods at a particular site of a given day type.
Work Block 1 is before 11 am
Work Block 2 is 11 am- 3 pm
Work Block 3 is $3 \mathrm{pm}-7 \mathrm{pm}$
Work Block 4 is after 7 pm

Day type There are two possible day types: weekdays and weekends; holidays are considered to be weekend days.

Time block - Each day is divided into 16 time blocks which are:

1) before 7 am
2) $7: 00-7: 59 \mathrm{am}$
3) $8: 00-8: 59 \mathrm{am}$
4) $8: 00-8: 59 \mathrm{pm}$
5) after 9 pm

## DESCRIPTION OF VARIABLES

| A | - | Number of boats actively fishing |
| :--- | :--- | :--- |
| B | - | Number of boats observed on a flight |
| C | - | Catch |
| C $^{\prime}$ | - | Catch of marked salmon |
| CPE | - | Catch per boat trip |
| E | - | Effort (estimated total number of boat trips) |
| I | - | Number of boats interviewed and fo $19 \mathrm{~A} \rightarrow$ been fishing |
| L | - | Number of boats landing |
| n | - | Number sampled |
| N | - | Population size from which n samples were observed |
| P | - | Proportion |
| T | - | Number of boat trips |
| V | - | Number found to be marked |
| W1 | - | Weighting factor to expand for all possiblllab it each site |
| W2 | - | Weighting factor to expand for all boats that landed in each work |

DESCRIPTION OF SUBSCRIPTS

| a | - | age |
| :--- | :--- | :--- |
| g | - | a set of landing sites |
| d | - | day type |
| i | - | site |
| j | - | work block |
| k | - | stint |
| l | - | landing time block |
| m | - | month |

the next boat landing at site $i$ and upon interviewing, found to have been fishing ( q ranges from 1 to n )
r - species
s - sub-Statistical Area
t - time block
$\begin{array}{lll}\mathrm{u} & - & \text { flight } \\ \mathrm{x} & - & \text { region }\end{array}$
y - annual

The description of terms, variables and subscripts used in the data analysis is given in Table C-1.

## Calculation of Catch and Effort Statistics

To estimate the monthly catch and effort, three components had to be calculated from a month's data:
(1) the weighted mean daily fishing pattern from interview data, (2) the weighted mean catch per unit effort from interview data and (3) the mean sport count from overflight data.

The equations used to estimate the means and variances for all catch and effort statistics are shown below.

Weighting factors used to estimate the daily fishing activity were calculated using the equations derived from DPA Consulting Ltd. (1982).

The data obtained from each shift were multiplied by the following weighting factor (W1) to expand for all possible stints at each site. The formula reads:

$$
\begin{equation*}
W 1_{d i j}=\frac{N_{d}}{n_{d i j}} \tag{1}
\end{equation*}
$$

where $N_{d}$ is the total number of days of type $d$ in that month and $n_{d i j}$ is the number of times the jth work block at the ith site was sampled on type d days.

The interviews aggregated by work block were multiplied by the weighting factor W2 to expand for all boats that landed in each work block. The formula reads:

$$
\begin{equation*}
W 2_{\text {dijk }}=\frac{L_{d i j k}}{I_{\text {dijk }}} \tag{2}
\end{equation*}
$$

where $L_{\mathrm{dijk}}$ is the number of boats landed and $\mathrm{I}_{\mathrm{dijk}}$ is the number of boats interviewed on the kth stint in the jth work block at the ith site on a day type d .

Therefore, the following equations can be used to calculate an unbiased estimate of the total monthly catch ( $\hat{C}_{d g r}$ ), fishing trips ( $\hat{T}_{d g}$ ) and fishing activity in time block $\hat{A}_{d g t}$ for each day type (d) where g is a set of landing sites (i). These formulas read:

$$
\begin{align*}
\hat{C}_{d g r} & =\sum_{i} \sum_{j}\left[W 1_{d i j} \sum_{k} \sum_{q}\left(W 2_{d i j k} C_{d i j k l q r}\right)\right]  \tag{3}\\
\hat{T}_{d g} & =\sum_{i} \sum_{j}\left[W 1_{d i j} \sum_{k} \sum_{q}\left(W 2_{d i j k}\right)\right]  \tag{4}\\
\hat{A}_{d g t} & =\sum_{i} \sum_{j}\left[W\left[1_{d i j} \sum_{k} \sum_{q}\left(W 2_{d i j k} A_{d i j k q t}\right)\right]\right. \tag{5}
\end{align*}
$$

where $\mathrm{C}_{\mathrm{dijkqr}}$ is the catch of species $r$ by the qth fishing party, and $\mathrm{A}_{\mathrm{dijkqt}}$ can equal 0 or 1 , thereby indicating whether the qth fishing party was actively fishing in time block $t$. Thus, the mean monthly catch per unit effort $\left(\mathrm{CPE}_{\mathrm{dgr}}\right)$ measured in terms of numbers of fish kept per completed boat trip, and proportion of daily fishing effort active during the hour of the aerial survey $\left(\mathrm{P}_{\mathrm{dgt}}\right)$ can be calculated with the following equations:

$$
\begin{gather*}
C P E_{d g r}=\frac{\hat{C}_{d g r}}{\hat{T}_{d g}}  \tag{6}\\
P_{d g t}=\frac{\hat{A}_{d g t}}{\hat{T}_{d g}}
\end{gather*}
$$

where CPE $_{\mathrm{dgr}}$ and $\mathrm{P}_{\mathrm{dgt}}$ are calculated for each day type (d) and group of landing sites (g).

The groups of landing sites reflect geographic areas with similar catch rates and/or activity patterns.

The estimated mean number of boats fishing during the hour of the sport boat count by overflight was calculated for each sub-Statistical Area using the following equation:

$$
\begin{equation*}
\bar{B}_{d s t}=\frac{\sum_{u} B_{s d t u}}{n_{d s}} \tag{8}
\end{equation*}
$$

where $B_{\text {sdtu }}$ is the number of boats observed fishing on flight $u$ at time $t$, in subStatistical Area s for day type d.

The mean sport boat count at the time of the overflight ( $\bar{B}_{d s t}$ ) and proportion of daily fishing effort active during the hour of the overflight ( $\mathrm{P}_{\mathrm{dgt}}$ ) were used in the following equation to calculate the total fishing effort for sub-Statistical Area s on day type d:

$$
\begin{equation*}
E_{d s}=\bar{B}_{d s t} \frac{1}{P_{d g t}} N_{d} \tag{9}
\end{equation*}
$$

where $\mathrm{N}_{\mathrm{d}}$ is the number of type d days in the month. Interview data for the subStatistical Areas fished (s) by anglers landing at each of the sites (i) within a landing group (g) were used to select the proportions ( $\mathrm{P}_{\mathrm{dgt}}$ ) that are appropriate for each mean boat count ( $\bar{B} d s t$ ).

The estimate for total effort by sub-Statistical Area and day type ( $\mathrm{E}_{\mathrm{ds}}$ ) and the weighted catch per boat trip for a group of landing sites by day type, area and species $\left(\mathrm{CPE}_{\mathrm{dgr}}\right)$ were used to calculate total catch for each species (r) and each sub-Statistical Area (s):

$$
\begin{equation*}
C_{s r}=\sum_{d}\left(E_{d s} C P E_{d g r}\right) \tag{10}
\end{equation*}
$$

The interview data were also used to select the catch per effort estimates $\left(\mathrm{CPE}_{d g r}\right)$ that should be applied to the effort estimates $\left(\mathrm{E}_{\mathrm{ds}}\right)$ for a specific sub-Statistical Area (s).

## Variance of Total Fishing Effort

The variance estimate for the number of boat trips in each sub-area was:

$$
\begin{equation*}
\operatorname{Var}\left(\left(_{d s u}\right)=\frac{\left(N_{d}-n_{d s}\right)}{\left(N_{d}-1\right)} \times \frac{\sum_{n=1}^{n} b_{d s u}^{2}-\frac{\left(\sum_{u=1}^{n} b_{d s u}\right)^{2}}{n_{d s}}}{\left(n_{d s}-1\right)}\right. \tag{11}
\end{equation*}
$$

where $b_{d s u}$ is the estimated number of boat trips on aerial survey $u$, in sub-area $s$, on day type $d$ and $n$ is the number of days when boat counts were conducted in sub-area $s$ on type $d$ days; and $N_{d}$ is the total number of type $d$ days in the month.

The variance estimate for the total number of boat trips in a given month for each day type and sub area was:

$$
\begin{equation*}
\operatorname{Var}\left(E_{b_{d s}}\right)=N_{d}^{2} \times \operatorname{Var}\left(b_{d s}\right) \tag{12}
\end{equation*}
$$

## Variance of Total Catch

The variance estimate for mean catch per effort was:

$$
\begin{equation*}
\operatorname{Var}\left(C P E_{d s i}\right)=\frac{\sum_{i=1}^{n i} c p e_{d s i}^{2}-\frac{\left(\sum_{i=1}^{n i} \times c p e_{d s i}\right)^{2}}{n i_{d s}}}{\left(n i_{d s}-1\right)} \tag{13}
\end{equation*}
$$

where $c p e_{d s i}$ is the catch per effort reported in interview $i$, for the sub-area or group of sub-areas $s$, on the day type $d$; and $n i_{d s}$ is the number of interviews for that stratum.

The variance for the total catch in each stratum was estimated by combining the variance for fishing effort and variance for catch per effort using the significant terms of a Taylor series expansion (Cochran 1963):

$$
\begin{equation*}
\operatorname{Var}\left(C_{s}\right)=\sum_{d=1}^{2}\left(E_{d s}^{2} \times \operatorname{Var}(C P E)_{d s}+C P E_{d s}^{2} \times \operatorname{Var}(E)_{d s}+\operatorname{Var}\left(E_{d s}\right) \times \operatorname{Var}(C P E)_{d s}\right) \tag{14}
\end{equation*}
$$

## Estimation of Marked Chinook and Coho Salmon

The incidence of marked (adipose-clipped) chinook and coho was recorded in each interview. The proportion of marks observed for each region, month and species ( $\mathrm{P}_{\mathrm{xmr}}$ ) was calculated as:

$$
\begin{equation*}
P_{x m r}=\frac{V_{x m r}}{n_{x m r}} \tag{15}
\end{equation*}
$$

where V is the number of marked fish observed and n is the number of fish inspected by region (x), month (m) and species (r).

The variance of each proportion was calculated as:

$$
\begin{equation*}
S_{P_{x m r}}^{2}=\frac{P_{x m r}\left(1-P_{x m r}\right)}{n_{x m r}} \tag{16}
\end{equation*}
$$

Monthly catch estimates of marked salmon were calculated as:

$$
\begin{equation*}
C_{x m r}^{\prime}=P_{x m r} C_{x m r} \tag{17}
\end{equation*}
$$

where $\mathrm{C}_{\mathrm{xmr}}$ is the estimated catch of species r in region x and month m .
The variance of the marked catch estimates was calculated as:

$$
\begin{equation*}
S^{2} C_{x m r}^{\prime}=P_{x m r}^{2} S^{2} C_{x m r}+C_{x m r}^{2} S^{2} P_{x m r}+S^{2} C_{x m r} S^{2} P_{x m r} \tag{18}
\end{equation*}
$$

where $S^{2} C_{x r r}$ is the variance of the catch estimates of species r in region x and month m .

The estimate annual proportions of marked salmon caught in each region (weighted by the corresponding regional annual catch estimates) were calculated as:

$$
\begin{equation*}
P_{x r y}=\frac{C_{x r y}^{\prime}}{C_{x r y}} \tag{19}
\end{equation*}
$$

where

$$
\begin{equation*}
C_{x r y}^{\prime}=\sum_{m} C_{x m r}^{\prime} \quad \text { and } \quad C_{x r y}=\sum_{m} C_{x m r} \tag{20}
\end{equation*}
$$

The variance of the annual proportions was calculated as:

$$
\begin{equation*}
S_{P x r y}^{2}=\left(\frac{C_{x r y}^{\prime}}{C_{x r y}}\right)^{2}\left[\frac{S_{C_{x r y}}^{2}}{\left(C_{x r y}^{\prime}\right)^{2}}+\frac{S_{C_{x r y}}^{2}}{\left(C_{x r y}\right)^{2}}\right] \tag{21}
\end{equation*}
$$

where $S^{2} C_{x y}$ is the variance of the annual estimated catch of species $r$ in region $x$.

## Estimation of Age Composition of Chinook Catch

Scale samples and length measurements were taken in a sub-sampling program during the interview process. Ages used in this report represent saltwater age of the fish.

The proportion of chinook at each age and month ( $\mathrm{P}_{\mathrm{am}}$ ) was calculated as:

$$
\begin{equation*}
P_{a m}=\frac{a_{m}}{n_{m}} \tag{22}
\end{equation*}
$$

where $a_{m}$ represents the number of fish observed at age a during month $m$, and $n_{m}$ is the total number of fish bio-sampled in that month.

The variance of each proportion was calculated as:

$$
\begin{equation*}
S_{a m}^{2}=\frac{P_{a m}\left(1-P_{a m}\right)}{n_{m}} \tag{23}
\end{equation*}
$$

The catch at age of chinook in each month was calculated as:

$$
\begin{equation*}
C_{a m}=P_{a m} C_{m} \tag{24}
\end{equation*}
$$

where $C_{m}$ is the estimated catch of chinook salmon in a given month $m$.
The variance of the catch at age estimate was calculated as:

$$
\begin{equation*}
S^{2} C_{a m}=P^{2}{ }_{a m} S^{2} C_{m}+C_{m}^{2} S^{2} P_{a m}+S^{2} C_{m} S^{2} P_{a m} \tag{25}
\end{equation*}
$$

where $S^{2} C_{m}$ is the variance of the month catch estimate $\mathrm{C}_{\mathrm{m}}$.
The annual catch at age was calculated as:

$$
\begin{equation*}
C_{a y}=\sum_{m} C_{a m} \tag{26}
\end{equation*}
$$

with a variance:

$$
\begin{equation*}
S^{2} c_{a y}=\sum_{m} S^{2} c a m \tag{27}
\end{equation*}
$$

The annual proportion at age (weighted by monthly catch) was calculated as:

$$
\begin{equation*}
P_{a y}=\frac{C_{a y}}{C_{y}} \tag{28}
\end{equation*}
$$

with a variance:

$$
\begin{equation*}
S_{P a y}^{2}=\left(\frac{C_{a y}}{C_{y}}\right)^{2}\left[\frac{S^{2} C_{a y}}{\left(C_{a y}\right)^{2}}+\frac{S^{2} C_{y}}{\left(C_{y}\right)^{2}}\right] \tag{29}
\end{equation*}
$$

*SOURCE: Coho catch statistics: 1960-1978 from Argue et al. (1983); 1979 from R. Kadowaki (Fisheries and Oceans Canada, Pacific Bio. Stn. Nanaimo, B.C. pers. comm.); 1980-1982 from unpublished creel survey data.

Chinook catch statistics: 1960-1977 from Argue et al. (1983); 1978 and 1979 from B. Riddell (Fisheries and Oceans Canada, Pacific Bio. Stn. Nanaimo, B.C. pers. comm.) following the methods of Argue et al . (1983); 1980-1982 from unpublished creel survey data.

Effort statistics: 1960-1979 from published and unpublished Fisheries Officer statistics; 1980-1982 from unpublished creel survey data.
**Effort prior to 1980 (the start of the creel survey) may not represent boat trips.

APPENDIX E-3. STRAIT OF GEORGIA HISTORICAL CATCH* AND EFFORT** GRAPH, 1960 TO 1982.

Historical Catch and Effort

*SOURCE: Coho catch statistics: 1960-1978 from Argue et al. (1983); 1979 from R. Kadowaki (Fisheries and Oceans Canada, Pacific Bio. Stn. Nanaimo, B.C. pers. comm.); 1980-1982 from unpublished creel survey data.
Chinook catch statistics: 1960-1977 from Argue et al. (1983); 1978 and 1979 from B. Riddell (Fisheries and Oceans Canada, Pacific Bio. Stn. Nanaimo, B.C. pers. comm.)
following the methods of Argue et al . (1983); 1980-1982 from unpublished creel survey data.
Effort statistics: 1960-1979 from published and unpublished Fisheries Officer statistics; 1980-1982 from unpublished creel survey data.
**Effort prior to 1980 (the start of the creel survey) may not represent boat trips.

## APPENDIX F. HISTORICAL REGULATION CHANGES AFFECTING THE STRAIT OF GEORGIA AND NORTHERN VANCOUVER ISLAND SPORT FISHERY*.

1981 July 1, chinook minimum size limit changed from 30 cm to 45 cm . Minor spot closures, E.g. River mouths only.

Annual bag limit established at 30 chinook.
1985 May 15, daily limit reduced from 4 to 2 chinook. June 5, annual limit reduced from 30 to 20 chinook. Spot closure plan implemented ( 32 closures), similar program continues to present day.

1988 April 1, annual bag limit reduced to 8 chinook. A proposed chinook minimum size limit of 62 cm (not enforced).

The Strait of Georgia has been divided into 2 areas: 1. Victoria area, Cadboro Bay to Sheringham Point. 2. The rest of the Strait of Georgia.

1989

Feb $1,62 \mathrm{~cm}$ minimum size limit for chinook.
Aug 16, Victoria area, minimum size limit for chinook reduced to 45 cm and the annual limit increased to 20 fish. Strait of Georgia, chinook size limit of 62 cm and an increase in annual limit to 15 fish.

Feb 6, daily limit for lingcod reduced to 1 and minimum size limit of 65 cm established.

Daily possession limit for coho reduced from 4 to 2 , minimum size limit increased from 30 cm to 41 cm .
Annual limit of 10 lingcod.
July 1, barbless hooks in tidal waters.
May 4, non-retention of coho in all tidal and non-tidal waters (some exceptions).
Creation of Red zones (no fishing) and Yellow zones (fishing allowed). Spot closures for sockeye.
*SOURCE: regulation changes 1981 and 1982, English et al. (1986); 1985 T. F. Shardlow, et al. (1989); 1988 T. F. Shardlow, et al. (1989); 1989 L. D. Collicutt et al. (1990); 1992, 1994 Wendy Grider (Fisheries and Oceans Canada, Vancouver, B.C. pers. comm).
APPENDIX G. SPECIES BREAK DOWN OF FISH COMMONLY INCLUDED WITH OTHER GROUNDFISH.

## Common Names

Pacific Cod
Pacific Tomcod
Walleye Pollock
Pacific Hake
Perch (all species)
Greenlings (all species)
gadus macrocephalus
Microgadus proximus
Theragra chalcogramma
Merluccius productus
Family Scorpaenidae
Family Hexagrammidae
APPENDIX H. TOTAL ESTIMATED EFFORT AND SPORT CATCHES FOR NORTHERN VANCOUVER ISLAND ( totals include data for all months sampled).
