## Canadian Manuscript Report of Fisheries and Aquatic Sciences

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers $1-900$ in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551.

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport manuscrit canadien des sciences halieutiques et aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui traitent des problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. II n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports manuscrits sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annual des publications scientifiques et techniques du Ministère.

Les numéros 1 à 900 de cette série ont été publiés à titre de manuscrits (série biologique) de l'Office de biologie du Canada, et après le changement de la désignation de cet organisme par décret du Parement, en 1937, ont été classés comme manuscrits (série biologique) de l'Office des recherches sur les pécheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de rapports manuscrits de l'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

Les rapports manuscrits sont produits a l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

# ADULT CHINOOK ESCAPEMENT ASSESSMENT CONDUCTED ON THE COWICHAN RIVER DURING 2001

ABSTRACT<br>Hop-Wo, N.K., D.A. Nagtegaal, E.W. Carter, and K. Jones. 2003. Adult chinook escapement assessment conducted on the Cowichan River during 2001. Can. Manuscr. Rep. Fish. Aquat. Sci. 2645: 45 p.

In 2001, the Biological Sciences Branch, Pacific Biological Station, continued a study of chinook salmon (Oncorhynchus tshawytscha) productivity in the Cowichan River. This in-depth escapement assessment project has been in place since 1988. Major components of this study included: i) enumerating spawners and total return, ii) estimating Native food fish catch, iii) recording hatchery broodstock removals, and iv) collecting biological, environmental and codedwire tag data. Population estimates for adult and jack chinook were determined based on the fence count data since this was considered to be the most accurate enumeration method. A carcass markrecapture study was conducted on the spawning grounds to augment the collection of biological data and to supplement the fence count population estimate. The total return of adult chinook to the Cowichan River was estimated to be 5,998 fish of which 3,282 spawned naturally in the river. A total of 1,732 adult chinook were collected for hatchery broodstock and 918 adults were reported as captured in the Native food fishery.

## RÉSUMÉ

Hop-Wo, N.K., D.A. Nagtegaal, E.W. Carter, and K. Jones. 2003. Adult chinook escapement assessment conducted on the Cowichan River during 2001. Can. Manuscr. Rep. Fish. Aquat. Sci. 2645: 45 p.

En 2001, la Direction des sciences biologiques, a la Station biologique du Pacifique, a poursuivi son etude sur la productivite du saumon quinnat (Oncorhynchus tshawytscha) dans la riviere Cowichan. Ce Projet de d'evaluation approfondie des echappees est en cours depuis 1988. Ses principaux volets sont les suivants: I) denombrement des geniteurs et des remontes totales, ii) e stimation des captures a des fins alimentaires par les Autochtones, iii) consignation du nombre de geniteurs preleves pour les ecloseries et iv) vollecte de donnees sur la biologie, l'environnement et les micromargues codees. On a estime la population d'adultes et de saumons d'un an enmer a partir des donnees sur le denombrement a la barriere, cette methode etant consideree commee la plus exacte. On a procede a la recuperation des micromarques sur les carcasses dans la frayere afin d'enrichir les donnees biologiques recueillies et de completer l'estimation de la population denombree a la barriere. La remonte totale de quinnats adultes dans la riviere Cowichan a ete estimee a 5998 unites, don't 3232 qui s'y sont reproduites naturellement. Au total, 1732 adultes on ete recueillis pour servir de geniteurs dans des ecloseries, tandis que 918 adults auraient ete captures dans le cadre de la peche a des fins alimentaires par les Autochtones.

## INTRODUCTION

Chinook stocks are invaluable to both commercial and recreational fisheries of the Pacific Northwest (Collicut and Shardlow 1995). In spite of protective measures, chinook salmon abundance has continued to decline. This trend has resulted in the recent addition of chinook to the list of threatened and endangered species in the United States (Waples 1991). The problem of declining stocks is similarly serious on the West Coast of Canada, and has potential ramifications regarding the sustainability of British Columbia's fishing industry (Argue et al 1983). Over the past several years, considerable interest has been focused on the chinook stocks of the southern portion of the Strait of Georgia due to the decline in these stocks and their importance to local fisheries (Farlinger et al. 1990). The Stock Assessment Division, Pacific Biological Station, initiated a study of chinook productivity to assess rebuilding strategies and to evaluate the effects of harvest management policies for these stocks. In the fall of 1988, a study was implemented on Cowichan River chinook with additional information collected from the Squamish and Nanaimo River stocks. These three stocks were identified as exploitation and escapement indicators and deemed to represent the status of all lower Georgia Strait chinook stocks. Since then, due to logistical reasons the Squamish River system was dropped as an indicator.

Major hatchery production of chinook on the Cowichan River began in 1980 (Cross et al. 1991). Chinook fry releases have increased from 64,681 in 1980 to 2.41 million in 2001. Coded wire tag releases also began in 1980 and by 2000 approximately $9 \%$ of the chinook released carried coded wire tags.

This report presents the results of the study completed during 2001. The objectives included:

1. enumerating chinook, coho and chum salmon migrating past the counting fence,
2. estimating the Native food fishery catch,
3. recording hatchery broodstock removals,
4. collecting biological data and sampling coded-wire tag (CWT) recoveries, and
5. implementing a carcass mark-recapture study for both adult and jack chinook.

## METHODOLOGY

A detailed description of the methodology is presented in Nagtegaal et al. (1994b). A summary of the methods is presented below along with any changes that were incorporated during 2001.

## STUDY AREA

The Cowichan River watershed is located on the Southeast coast of Vancouver Island and drains an area totalling $826 \mathrm{~km}^{2}$. The Cowichan River system includes Cowichan, Bear, Mesachie, Somenos, and Quamichan lakes. Cowichan Lake ( $62 \mathrm{~km}^{2}$ ), the largest of the five lakes, is situated approximately 50 km west of the Cowichan Bay estuary. Discharge from a flow
control dam situated at the outlet of Cowichan Lake ranges from 7 to $326 \mathrm{~m}^{3} \cdot \mathrm{~s}^{-1}$, and averages $44.9 \mathrm{~m}^{3} \cdot \mathrm{~s}^{-1}$ (Feilden and Holtby 1987). A total of 26 tributaries drain into the Cowichan River. The largest of these is the Koksilah River, which intersects the mainstem of the Cowichan River approximately 2.5 km upstream of the estuary. The Cowichan River watershed system is a typical Vancouver Island and coastal British Columbia stream in which maximum flows occur during winter months due to heavy rainfall (McDougall 1985).

The Cowichan River supports many salmonid species including chinook (Oncorhynchus tshawytscha), coho (Oncorhynchus kisutch), chum (Oncorhynchus keta), sockeye (Oncorhynchus nerka), and pink (Oncorhynchus gorbuscha) salmon; as well as cutthroat trout (Salmo clarkii), steelhead trout (Salmo gairdnerii), kokanee salmon (Oncorhynchus nerka), and dolly varden char (Salvelinus malma). Attempts have been made to introduce several other species including: atlantic salmon (Salmo salar), brown trout (Salmo trutta), and speckled char (Salvelinus fontinalis) (Perrin et al. 1988). The salmonids of the Cowichan River support several vital fisheries, which include a Native food fishery, tidal sport fishery, and a large commercial ocean fishery.

## ENUMERATION FENCE

The counting fence was placed upstream of the city of Duncan, in the same location as in previous years (Figure 1). The design incorporated a resistance board weir with a counting raceway (adjustable flashboard) and trap box adjacent to a counting tower equipped with floodlights. Counts were continuously recorded by 15 -minute interval for adult and jack chinook, adult and jack coho, and chum salmon. If identification was in doubt fish were recorded as unknown. Water depth, temperature, and clarity, and weather condition were recorded three times per day. The fence was checked daily for any breeches and cleaned of leaves and other debris. Any removals of broodstock at the fence site by hatchery staff were recorded.

## SWIM SURVEYS

In an effort to maintain consistency with historical data sets, swim surveys were conducted, in conjunction with Cowichan Tribes Aboriginal Fisheries Management (CTAF), to estimate the spawning population of chinook. Swims were generally made in the upper section of the river (Figure 1) with counts extrapolated to the total system. Each survey was conducted by three experienced swimmers while one person in a canoe recorded the data. Each swimmer (one in the middle and one on each side of the river) counted the fish seen within their range of visibility. The three swimmers attempted to keep abreast as they approached each pool while the person in the canoe lagged behind within hailing distance. Counts were recorded by pool/riffle and then compiled by river section. To maintain consistency in counting procedures the same swim team was used for each survey whenever possible. Based on the historical distribution of spawners, swim counts were expanded by a factor of 3.4 to derive an estimate of total escapement (Nagtegaal et al. 1994a). This expansion factor was consistently applied to swim counts with no adjustments made for run timing or changes to spawner distribution. A final escapement estimate was then
determined based on consultation with Fishery Officers using the swim counts in conjunction with other anecdotal information.

It was intended that the swim survey estimates remain independent of the fence count. However, even though fence counts were not passed on to the swim teams during the season, general trends in escapement numbers were known.

## NATIVE FOOD FISHERY

In 1990, a systematic approach was developed by the Cowichan Tribes Aboriginal Fisheries Management (CTAF) program to monitor the fishery more closely and to better estimate the Native food fish catch (Paige 1992, 1997). This approach involved recording catch and effort by management zone within the Native fishing boundaries (Figure 2). A crew of four observers patrolled the fishery on a daily basis and interviewed fishermen for numbers caught by area and total time spent fishing. In this way, weekly estimates of catch per unit effort (CPUE) were obtained. CPUE was adjusted for daily changes in fishing effort and differences in effort among fishing zones. These data were then extrapolated over time and area to estimate total catch by week and summed over all weeks to estimate the total catch for 2001.

$$
C A T C H \equiv \sum_{n}^{w=1} C P U E_{w} \times E F F O R T_{d}
$$

where $w$ refers to the time interval for catch (week), and $d$ refers to the time interval for effort (day). No confidence limits were calculated (Paige 1997).

For some years since 1988, an observer was employed to independently collect catch and biological data from the in-river Native fishery. Due to budget constraints no observers were employed from 1999-2001 and CTAF catch estimates could not be independently verified.

## BIOLOGICAL DATA

Biological data for chinook were collected from hatchery broodstock samples and from carcasses recovered on the spawning grounds. Data collected included sex, post-orbital hypural $(\mathrm{POH})$ length, and adipose fin status (present/absent). Scales were also taken for age analysis and the heads were removed from all adipose fin clipped fish for recovery and decoding of coded-wire tags (CWT). Hatchery staff randomly collected biological data from approximately $25 \%$ of the chinook broodstock and from all chinook identified as carrying a CWT. All chinook recovered on the spawning grounds were sampled and spawning condition was noted.

## MARK-RECAPTURE

A mark-recapture program involving the tagging and subsequent recovery of chinook jack and adult carcasses was conducted on the spawning grounds. Crews consisting of two or three individuals surveyed the upper section of the river each day using an inflatable boat (Figure 1). All
chinook carcasses encountered were individually tagged with a Ketchum ${ }^{1}$ aluminum sheep ear tag on the left operculum and immediately released in the same area as captured. Location of capture and release, tag number, spawning condition, POH length, sex, and adipose fin status (present or absent) were recorded for each carcass. Tag number and recovery location were recorded for all previously marked carcasses, which were then returned to the river at the capture site.

The section of the river selected for the mark recapture study is located above Skutz Falls and represents the area where the majority of chinook spawning has typically occurred. A 4.2 m pole with a gaff hook attached to the end was used to recover carcasses. Carcasses that ended up in deep pools were occasionally unable to be retrieved.

## POPULATION ESTIMATE

Adult chinook salmon escapement estimates were generated from the carcass markrecapture data using the Petersen model (Chapman modification) stratified by sex (Ricker 1975). Data was stratified to minimize the effects of differential tagging and tag recovery between sexes. This study follows the estimation procedure as outlined in previous reports (Nagtegaal et al. 1994a, 1994b, 1994c).

To determine the validity of the mark recapture estimate, potential biases were assessed to test for violations of the assumptions inherent in the Petersen mark recapture method (Ricker 1975; Seber 1982; Krebs 1989). Sex related bias in the application sample was examined by comparing the sex ratio of the marked versus the unmarked recoveries. Sex related bias in the recovery sample was assessed by comparing the sex ratio of recovered samples with unrecovered samples. Size bias in the application sample was examined by comparing the lengths of marked versus unmarked recoveries. Size bias in the recovery sample was examined by comparing the lengths of the recovered and unrecovered tag samples. Statistical comparisons of the length data were carried out using pooled variance Student's t-test. Temporal bias in the application samples was assessed by stratifying sampling dates into approximately equal periods and comparing mark incidence among strata. Similarly, temporal bias in recovery samples was stratified by dates and the ratio of tagged recoveries to tags applied was compared. Statistical assessments of sex and period biases were carried out using Chi-square tests.

## RESULTS

## ENUMERATION FENCE

The enumeration fence was installed upstream from the City of Duncan at the traditional site (Figure 1) and was operational from September 4th to November 1st. Water conditions were clear for most of the study with only two days noted as cloudy and nine days as partially cloudy (Table 1). As a result, conditions were ideal for viewing fish migration past the counting tower

[^0]and all counts are deemed to be reliable. A total of 3,361 chinook adults, 1,454 chinook jacks, 15,436 coho adults and 1,296 coho jacks were counted migrating past the enumeration fence. In addition, 7,859 chum and 243 unidentified fish were enumerated at the fence site (Table 1). Since there were no breeches of the fence during the project it was assumed that all fish migrating past the fence during the study period were enumerated.

In past years, chinook jacks have been prominent during the early segment of the return migration often matching adult chinook counts. In 2001, the proportion of jack chinook mirrored the overall temporal pattern of adult chinook migration past the fence (Table 1, Figures 3a, 3b).

The pattern of daily migration past the fence was examined by summarizing hourly counts throughout the program (Table 2). A major peak in migration for both adult and jack chinook occurred between 0700 and 1000 hrs. During this period, $32.9 \%$ of adult chinook and $42.0 \%$ of jack chinook moved past the fence site (Table 2).

In past years, tower counts and species identification were verified on several occasions throughout the run by capturing all fish migrating past the fence during one counting segment in the upstream trap box. For logistical reasons, this practise was not carried out in 2001.

## SWIM SURVEYS

A summary of all visual surveys conducted by DFO Fishery Officers and by the Cowichan Tribes Aboriginal Fisheries Management group from 1981 to 2001 is presented in Table 3. Total escapement estimates for each year include adult chinook only. In 2001, two swim surveys were conducted in the upper section of the river (Figure 1) and one survey conducted in the lower section of the river (Figure 2).

## NATIVE FOOD FISHERY

Historical estimates of the number of chinook captured in the in-river Native food fishery are presented in Table 4 and Figure 4. The 2001 catch estimate of 918 adults and 120 jacks was determined by the Cowichan Tribes Aboriginal Fisheries Management group (Figure 2). While it is difficult to assess the quality of the data collected, the catch estimate is considered to be a minimum. Also, if non-catch mortality (fish that escaped capture but died before spawning due to fishery induced injuries) were included, the impact of the fishery would likely be much more significant.

## HATCHERY COMPONENT

Between September 18 and October 3, Cowichan River hatchery staff collected 680 male and 818 female chinook from the river downstream of the fence. In addition, 108 male and 126 female chinook were collected upstream of the fence (Table 5). The total number of chinook removed from the river for hatchery broodstock was within the range required for hatchery
production (Table 6). Age analysis of scale samples revealed that the majority of adult fish ( $95.6 \%$ ) used in broodstock were either three or four years old (Table 7).

## BIOLOGICAL DATA

A total of 229 male, 463 female and 182 jack chinook carcasses were recovered on the spawning grounds and measured for post orbital-hypural length (Table 8). Conditions for the recovery of carcasses were ideal with discharge levels below the long-term average during October and November (Figure 5). The length of adult male chinook carcasses ranged from 40.9 to 82.5 cm and averaged 63.0 cm , while female carcasses ranged from 40.9 to 82.5 cm and averaged 65.2 cm . Jack chinook carcasses ranged in length from 28.6 to 55.5 cm and averaged 38.6 cm . A total of 11 male, 15 female and three jack chinook carcasses recovered from the spawning grounds were missing an adipose fin indicating the presence of a coded-wire tag (Table 8). These values represent $4.8 \%, 3.2 \%$ and $1.6 \%$ of the total male, female and jack carcasses recovered. The majority of adult chinook were three or four years old ( $54.1 \%$ and $41.4 \%$, respectively) while most fish identified as jacks ( $98.9 \%$ ) were two years old (Table 9).

A total of 178 male, 217 female and seven jack chinook were randomly collected for broodstock sampling (Table 10). Post orbital-hypural length measurements of male chinook ranged from 48.0 to 78.5 cm and averaged 59.3 cm , female chinook ranged from 49.5 to 83.3 cm and averaged 64.6 cm , and jack chinook ranged in length from 38.0 to 51.0 cm and averaged 44.4 cm . A total of zero male, 16 female (representing $7.4 \%$ ) and zero jack chinook were missing an adipose fin indicating the presence of a coded wire tag (Table 10).

There was a statistically significant difference between the length of both male and jack chinook carcasses recovered on the spawning grounds and those sampled for hatchery broodstock (Student's t -test: $\mathrm{t}=4.948 ; \mathrm{p}<0.01$ and $\mathrm{t}=3.832 ; \mathrm{p}<0.01$, for males and jacks respectively). In both cases, the broodstock sample was significantly larger than the samples collected on the spawning ground. However, there was no significant difference between the lengths of female chinook sampled on the spawning grounds or sampled at the hatchery (Student's t -test: $\mathrm{t}=1.235$; $\mathrm{p}<0.01$ ).

A significant difference is evident when comparing the rate of adipose fin clips of chinook sampled from the spawning grounds and chinook sample from hatchery broodstock (Chi-square 8.788; $\mathrm{p}=0.05$ for males and Chi-square $=5.802 ; \mathrm{p}=0.05$, for females). Adult male chinook have a higher rate of clipped adipose fins while female chinook have a lower rate of clipped adipose fins when sampled on the spawning grounds compared to broodstock sampling (Table 8,10). The broodstock sampling size of jack chinook was too small for statistical comparison.

Coded wire tags were recovered from 26 chinook carcasses sampled on the spawning grounds. The majority of these fish ( $84.6 \%$ ) were adults from the 1998 brood, of which $59.1 \%$ were released as part of the upper Cowichan River (late) release strategy (Table 11). Three CWT recoveries ( $11.5 \%$ ) were jack chinook from the 1999 brood year. A summary of all chinook releases from the Cowichan hatchery since 1979 is presented in Table 12.

## ENVIRONMENTAL INFORMATION

Environmental data collected at the fence site included water temperature, visibility and river depth (Table 1). Water temperature was generally higher at the start of the study and decreased discontinuously to the end of October. Water temperature over this period ranged from 9.0 to $18.9^{\circ} \mathrm{C}$ and averaged $15.3^{\circ} \mathrm{C}$. Water depth at the fence site was consistently low until the last week of September where water levels rose and fell throughout the first three weeks of October. During the last week of October the water level continued to rise until fence removal (Figure 3b). Water depth over the study period ranged from 42.7 to 89.0 cm and averaged 55.0 cm . Water clarity was recorded in the form of a visibility code. For the majority of the study, visibility at the fence site was clear. Only nine days were recorded as moderately cloudy (code 1 2 ) and two day as cloudy (Table 1).

River discharge was recorded at the Water Survey Canada station below the Island Highway Bridge in the City of Duncan (Table 13, Figure 1). River discharge during the course of the 2001 study was lower then the 30 -year average during the September and October but above average during November and December (Figure 5).

## CARCASS MARK-RECAPTURE

Between November 5 and December 7 a total of 227 male, 465 female and 181 jack chinook carcasses were tagged and released in the upper Cowichan River (Table 14a, 14b). Of the 163 carcasses recovered with tags, 41 ( $25.2 \%$ ) were male, 109 ( $66.9 \%$ ) were female, and 13 ( $8.0 \%$ ) were jack. Using the Petersen estimator, the adult chinook spawning ground population size was determined to be 3,869 fish ( $95 \%$ CI: 3,311 to 4,427 ), while the jack population was estimated to be 2,535 fish ( $95 \% \mathrm{CI}$ : 1,299 to 3,771 ) (Table 15).

## Potential Biases

The assessment of sampling selectivity had several potential biases in the carcass mark recapture study.

1. Temporal bias: Temporal bias in the tagging sample was examined by stratifying the mark incident rate into four recovery periods (Table 16). There was a significant temporal bias in the application sample for both male and female adult chinook when the data was stratified into four equal recovery periods (Chi-square $=14.86 ; p=0.05$ and Chi-square $=21.13 ; p=0.05$, for males and females, respectively). Mark incidence increased during each recovery period.

Temporal bias in the recovery sample was analysed by stratifying the recovery rates into four application periods (Table 17). A statistical difference in the recovery sample for both male and female adult chinook was observed (Chi-square $=24.19 ; p=0.05$ and Chi-square $=15.77$; $\mathrm{p}=0.05$, males and females, respectively). The recovery rate increased during each successive application period.
2. Fish Sex: Sex related bias was examined by comparing the sex ratio of the marked and unmarked spawning ground recoveries by application sample and by recovery sample. No sex related bias was evident when comparing male and female chinook populations (Chi-square $=2.60 ; \mathrm{p}=0.05$ and Chi-square $=1.85 ; \mathrm{p}=0.05$, application sample and recovery sample, respectively) (Table 18). However, when jack chinook were included in the assessment both the application and recovery samples showed significant bias (Chi-square $=22.76 ; \mathrm{p}=0.05$, and Chisquare $=16.61 ; p=0.05$, application sample and recovery sample, respectively) (Table 19).
3. Size bias: Size related bias was examined by comparing the POH mean lengths of unrecovered marked chinook and recaptured chinook by sex. No size bias was evident in the recovery sample for adult males and jack chinook (Student's $t$-test: $t=1.481 ; p<0.01$ and $t$ test $=1.771 ; \mathrm{p}<0.01$ for males and jacks respectively). However, there was a significant size difference in the recovery sample of adult females (Student's t -test: $\mathrm{t}=2.658 ; \mathrm{p}<0.01$ ).

## POPULATION ESTIMATE

Escapement and total return estimates for 2001 were determined using fence count data since this is considered to be the most accurate enumeration method. However, after reviewing both spawning ground carcass recovery and hatchery broodstock collection data, it became evident that the chinook fence count did not accurately reflect the true jack to adult ratio. Analyzing the lengths of jack and adult chinook with the traditionally accepted jack designated length of 450 mm revealed an overlapping of age groups (Figure 6). As a result, the spawning ground carcass recovery data was utilized to apportion the total chinook fence count with a more reflective ratio of jack and adult chinook populations. This was accomplished by comparing age data with length data to calculated the proportion of 2 years old jack chinook with lengths greater then $450 \mathrm{~mm}(9.2 \%)$ and the proportion of 3 years old or greater adult chinook with lengths of 450 mm or less $(0.6 \%)$. The fence count data was then adjusted by these proportions yielding total chinook fence counts of 3,057 adults and 1,758 jacks. Since previous studies have indicated that approximately $15 \%$ of the chinook run arrives after late October (Nagtegaal and Carter 1998), the total fence count was expanded by this value and the final estimate of adult chinook migration past the fence site was 3,516 fish.

The number of natural spawning adult chinook in the Cowichan River during 2001 was determined to be the fence count, plus an additional $15 \%$ estimate for chinook arrival after fence removal (Nagtegaal and Carter 1998), minus any broodstock removals from areas above the fence. Following this methodology, the total number of adult chinook spawning in the Cowichan River was estimated to be 3,282 fish (Table 20).

The total return of adult chinook to the Cowichan River was determined to be the sum of the total fence count with the addition of broodstock removals and the Native fishery catch. A further 300 fish were added to this total to account for chinook lost to seal predation in the Cowichan estuary (see discussion for details). Following this methodology, the total return of adult chinook to the Cowichan River was estimated to be 5,197 fish (Table 20).

## DISCUSSION

## ENUMERATION FENCE

The floating fence design functioned well in the flow conditions that existed in the lower Cowichan River during the fall of 2001. While the fence was intended to be self-cleaning, field staff were required to regularly remove leafy debris from the fence panels during periods of heavy rain and related high flows. During such periods, fence panels became over burdened and could not remain afloat without the removal of debris. While this difficulty has been observed in other fence studies (Cousens et al. 1982, Johnston et al. 1986) it is likely that the intensity of the problem varies by year and location.

During many of the past monitoring studies, high flows have caused fence damage or forced early removal resulting in incomplete fence counts. During the current study, the enumeration fence was operational throughout the monitoring period and a complete count of all fish passing the site was attained. However, since the fence was removed on November 1 there was likely a portion of the chinook run that arrived after fence removal. Past studies have indicated that approximately $15 \%$ of the chinook run arrives after October 30 (Nagtegaal and Carter 1998). Based on this observation, the adult chinook fence count was expanded by $15 \%$ to account for unassessed spawners.

Several of the past fence enumeration studies conducted on the Cowichan River have noted the mis-identification of jack versus adult chinook by observers monitoring the migration of chinook past the fence (Nagtegaal and Carter 1998, 2000). While trap box verifications of observer counts were not carried out in 2001, it became clear from both spawning ground and hatchery broodstock data that the adult to jack ratio recorded at the fence was not reflective of the true population parameters. Since there were a large number of jack chinook at the upper end of the size distribution, it appears as if many of these fish were counted as adults. This seems likely as it would be very difficult to determine the size of a moving fish to within a few centimetres when viewing them from a counting tower well above the river. As a result, the total chinook fence count was adjusted by the ratio of adult and jack chinook sampled during the spawning ground carcass recovery.

## SWIM SURVEYS

Among the biases typically associated with swim surveys, the extrapolation of actual swim counts to total estimates warrants some consideration (Burns unpubl.). Assumptions concerning the distribution of chinook in the river at the time of the survey are the basis for expanding these counts to estimate total escapement (T. Fields, 230 Underwood St., Duncan, B.C. V9L-3X3: pers. comm.). In 1991, it became apparent that during high water flow conditions in early fall, expansions based on the swim survey results overestimated total escapement (Nagtegaal et al. 1994b, 1994c). The results of the 1992 swim surveys support the hypothesis that during low water flow conditions in late fall, expansions based on swim survey results underestimate the number of spawners. Low flow conditions lead to an underestimation of spawners because the distribution of fish in the river
is affected by water flow. Generally, in low water years, not as many fish make it to the traditional spawning areas above Skutz Falls. The expansion of swim surveys conducted in the upper area alone tends to underestimate the number of fish. Conversely, during high water years most of the fish make it above Skutz Falls so the expansion factor tends to overestimate the number of fish.

## NATIVE FOOD FISHERY

Catch estimation procedures developed by the Cowichan Tribes Aboriginal Fisheries Management unit have not been assessed by stock assessment staff. As a result, no comments can be made regarding the methodologies used. The 2001 estimate of 918 adult chinook was a considerable increase over 1999, and 2000 years (Table 4). In past years, independent observer estimates of adult chinook catch have been 2 to 3.5 times higher than the CTAF estimate. Since no observers were employed during 2001, CTAF catch estimates could not be independently verified.

## BIOLOGICAL DATA

Male and female chinook collected by the hatchery for broodstock were significantly larger than the carcasses recovered on the spawning ground. This suggests that either one or both sampling methods were size selective or that different size components of the returning chinook population were available for sampling at each site. Since deadpitch carcass recovery is generally selective for larger fish (Tschaplinski and Hyatt 1991) and carcass sampling occurred throughout the spawning period, it seems unlikely that selectivity in this sampling method could explain the result. Also, since broodstock collection occurred over an extended period and beach seines were employed in the capture of fish (a relatively non-selective gear), selectivity seems unlikely. However, since not all chinook captured in each set were taken for broodstock, it may be that the smaller fish were released back into the river. This would result in larger than average fish being included in the broodstock sample while smaller than average fish were returned to the river to contribute to the spawning ground carcass recovery sample. The selective retention of larger broodstock could explain the observed result.

## MARK RECAPTURE

The carcass mark-recapture portion of the Cowichan River chinook stock assessment project was implemented many years ago for several reasons. First, since handling fish at the fence site caused significant migration delays this practice was abandoned to ensure chinook reached the spawning grounds without undue stress. As a result, no representative biological samples were available for assessment. While length and age data were collected by hatchery staff during broodstock capture, this data was not consistently representative of the spawning population. The sampling of carcasses from the spawning ground provided an additional source of biological data, which when pooled with the hatchery sample was more representative of the true population. Second, the recovery of coded-wire tags from hatchery broodstock did not provide an adequate sample size for a rigorous assessment. Spawning ground carcass recoveries supplemented the hatchery sample and strengthened the coded-wire tag analysis. Finally, since
high flows in past years have caused fence damage that resulted in incomplete enumeration of spawners, an additional method of providing a population estimate was required.

Population estimates for adult and jack chinook were determined using the pooled Petersen estimator. Since the true population size was not known, a direct measure of the accuracy of the estimates was not possible. However, an assessment of the underlying assumptions of equal probability of capture, simple random recovery sampling and complete mixing can usually be made by testing recovery and application samples for temporal, spatial, sex and size related biases (Schubert 2000). To carry out most of the bias assessments, different gear types must be utilized for capturing the tag application and the recovery samples. In the current study, spawning ground carcass recovery was used to attain both samples thus limiting the ability to assess sample biases.

The assessment of sampling selectivity revealed several biases in the carcass markrecapture study. First, there was a significant temporal bias in the application sample for both male and female chinook. The assessment revealed that tag incidence was very low during the early period and extremely high during the last period. This is likely due to the nature of the carcass recovery study, since tagging and recovery were concurrent activities. As a result, there were very few tagged carcasses available for recovery in the early period and as the number of tags in the population accumulated towards the end of the study, the tag incidence in the later periods was much higher. There was also a temporal bias in the recovery sample for males and females. Once again this bias was primarily due to the nature of the study since tags applied in later periods were less likely to be recovered as they were only available for recovery for a short period.

No sex related bias was evident in the application or recovery samples for adult chinook; however, when jacks were included in the assessment both samples showed significant bias. This is likely due to the size difference between adult and jack chinook, which effects the way carcasses behave in the river. Since jack carcasses are much smaller, they are more easily flushed out of the recovery area by small increases in river flow. As a result, they are less likely to be recovered than adult chinook carcasses.

Size bias testing did not provide an assessment of the size selectivity of the sampling method since both application and recovery samples were attained using the same method. Rather, the size bias assessment provided an evaluation of the recoverability, based on size, of tagged carcasses that were redistributed back into the river after tagging. Testing revealed that there was no size bias for male or jack chinook, yet statistically longer female chinook were recaptured after being tagged. However, length distributions of tagged female chinook and recaptured female chinook are similar and bias to the mark-recapture estimate would be minimal.

The detection of sampling biases usually results in the use of a stratified estimator; however, Schubert (2000) compared the performance of several mark-recapture population estimators for a sockeye salmon population of known abundance and concluded that the pooled Petersen estimator was less biased and preferred over stratified estimators. In that study, the Schaeffer estimator would not improve accuracy and it was recommended that the method be abandoned for use in population estimation. Also, it was determined that while the maximum
likelihood Darroch estimator could potentially improve accuracy there was no obvious way of selecting between accurate and highly biased estimates. Parken and Atagi (2000) found that pooled and stratified estimators of Nass River summer steelhead produced similar escapement estimates but that the pooled estimator was more precise and had less statistical bias than the stratified estimator. These findings indicate the robust nature of the pooled Petersen estimator and suggest that its use to determine population abundance from mark-recapture data is generally appropriate under a wide range of circumstances.

## SEAL PREDATION

Although seal predation was not directly assessed in this study, it is worthwhile to examine the impact seals have on chinook in Cowichan Bay. In 1988, the number of seals gradually increased from a low of 30 in April to a peak of about 100 in December. According to Olesiuk et al. (1990) harbour seals consume an estimated 9 tonnes of salmon annually in Cowichan Bay. An estimated 23\% (Sept.) to $48 \%$ (Nov.) of the harbour seals' diet in Cowichan Bay was comprised of salmon (Bigg et al. 1990). Based on these data, consumption of chinook salmon could potentially range from 100 to 500 adults. These data were collected in 1988 when low flows in the Cowichan River persisted until the end of October. Predation likely increases the longer chinook salmon remain in the estuary waiting for high water to allow upstream migration. While low flow conditions occurred during September and October, 2001, Fishery Officers observations indicated that seal and sea lion populations have remained constant for the last couple of years in Cowichan Bay. As a result, predation on chinook was estimated to be approximately 300 adults.

## POPULATION ESTIMATE

The 2001 Cowichan River chinook population estimate was based on the enumeration fence count. Moderate river flows allowed the fence to remain in place without significant breeches for the duration of the study and it was felt that a near complete census was attained. The estimate of the number of natural spawning adult chinook migrating past the fence site of 3,282 was just below the $95 \%$ confidence limits of the 3,311-4427 adult chinook mark-recapture estimate. This over-estimation by the mark-recapture estimate may be due to higher than average water flow during the mark-recapture sampling period (Figure 5). Higher than normal water flow would decrease the number of carcasses recaptured resulting in an over-estimation of the actual chinook population.

The estimated number of adult spawners was the third lowest since 1975, below the period average of 5,651 and well below the escapement goal (Table 20, Figure 7). This could partially be due to low hatchery contribution in 1997, which would have decreased the return of four year old hatchery chinook (Figure 8). Natural and enhanced contributions to Cowichan River chinook escapement from 1982 to the present can be found in Table 9.

## ACKNOWLEDGEMENTS

We would like to thank Ron Zenner, James Patterson, Michael Folkes, Candace Boyle, Phillip Joe, Dave Key, Dave Burton, Kevin Timothy, Ashley Pifko, Frank Sutherland, Phil Burrash, Chad Stewart, and Stephan DeLeeuw for their involvement in the implementation of the enumeration fence, collection of migration and biological data. We thank W. Jansen and E. Teskey, Fisheries and Oceans Canada Fishery Officers stationed in Duncan, for their helpful assistance. We thank the Cowichan Tribes Fisheries Management Unit, in particular Wayne Paige, Jed and Doug August, and Wayne Paige Jr. for their cooperation and assistance in acquiring Native food fishery data and swim survey results. We thank Doug Millerd, manager of the Cowichan hatchery, for providing broodstock capture and biosampling data. We thank the conscientious sport fishers who returned the Ketchum tags from the chinook they caught in the Cowichan River. We thank the City of Duncan for allowing us to use their access road to the counting fence site and granting us storage space, power and water from their pumphouse facility. We thank C. Harlow, from Fisheries and Oceans Canada, B. Hollingshead, the Regional Water Manager for British Columbia, and A. Jezierski from Norske Canada for coordinating the water release management plan for the Cowichan River.

${ }^{1}$ S - Swim survey, H - Helicopter survey, F - boat survey
${ }^{2}$ Refer to Figure 1.
${ }^{3}$ Total escapement estimate for adult chinook.
${ }^{4} 516$ chinook carcasses were counted in this total.
${ }^{5} 28$ chinook carcasses were counted in this total.
${ }^{6}$ Swim surveys conducted by Cowichan Tribes River Management Unit, total escapement determined by Fishery officers.
${ }^{7}$ Adult population estimate based on swim survey records was not feasible due to extremely low water conditions during swim survey.
${ }^{8}$ Swim Survey took place in the lower Cowichan River from Black Bridge to Green Point (Figure 2).

${ }^{1}$ Includes chinook caught in both the spear fishery and the in-river gillnet fishery.
${ }^{2}$ Since 1988, data has been collected by the Cowichan Tribes River Management unit. Prior to 1988, data were collected by local Fishery Officers.
${ }^{3}$ Estimates for jack chinook were not provided in 1997, 1998 and 2000.

Table 5. Summary, by day and location, of chinook broodstock collected by the Cowichan River hatchery during 2001.

1 Cowichan Hatchery release strategies for chinook:
Upper Cowichan River (late): raised to pre-smolt size (5-6 g) prior to release approximately
3 km below the weir in May.
Upper Cowichan River (early): raised to fry ( 3 g ) prior to release approximately
3 km below the weir in early April.
Cowichan Lake Pen: raised to pre-smolt size ( $5-6 \mathrm{~g}$ ) prior to release just above the weir in May.
Hatchery (late): raised to pre-smolt size (5-6 g) prior to release at the hatchery in May.
Seapen: raised to smolt size $(6+\mathrm{g})$ prior to release from the netpens in Cowichan Bay in early June.

| 2001 | $3282^{5}$ | 1732 | 89 | $6692^{4}$ |
|  |  |  | 918 | $7024^{4}$ |
|  |  |  |  | $5998^{4}$ |

${ }^{1}$ For the years 1989 to the present, the number of natural spawners was calculated as the number of adults recorded at the fence minus the adults removed for broodstock above the fence. In years when fence counts were incomplete, the cumulative run timing curve was used to expand the count.
${ }^{2}$ This number is the total broodstock removed and may include some jacks.
${ }^{3}$ Due to early flooding, estimate is based on expansion of swim surveys and weir counts.
${ }^{4}$ Includes an estimated 300 chinook lost to seal predation in the Cowichan estuary.
${ }^{5}$ For the years 2000 to the present, the adult fence count totals used in calculating natural spawners was adjusted using jack/adult ratios obtained from the spawning grounds.

## Fig. 1 Cowichan River Survey Areas:

## Swim survey locations were:

> 1 - Bird House Pool
> 2 - Road Pool
> 3 - Train Trestle (mile 70.2)
> 4 - Old Pick-up Site
> 5 - Maple Tree
> 6 - Three Firs Pool
> 7 - Skutz Falls
> 8 - Marie Canyon
> 9 - Bible Camp
> 10 - Cowichan Side channel
> 11 - Sandy Pool
> 12 - Sewer
> 13 - JC Pool

## Swim survey areas:

Bird House (1) to Three Firs pool (6) represents the Upper survey section.
Marie Canyon (8) to enumeration fence (A) represents the Middle survey section.
A - refers to the adult enumeration fence

## Tag recovery locations:

Locations numbered 1 to 45 are in the upper river section, those numbered 46 to 83 are in the middle river section.

F-Brian's pool to Clem Clem and part of Koksilah

G-Clem Clem to mouth
H-North side to Four plex
I-Four plex to Meriner's slough

J-Meriner's slough to mouth

Figure 3a. Daily fence counts of adult and jack chinook and water temperature at the fence site.

Figure 3b. Daily fences count of adult and jack chinook and water depth at the fence site.

Figure 4. Adult chinook catch in the Cowichan First Nations fishery for the years 1971 to 2001.

Figure 5. Monthly Cowichan River discharge ( $\mathrm{m}^{3} / \mathrm{s}$ ) in 2001 along with historical values.

Figure 6. Adult and jack chinook length frequencies collected from the Cowichan River spawning grounds, 2001.

Figure 7. Annual adult chinook escapement estimates for the Cowichan River for the years 1953 to 2001 .

Figure 8. Annual releases of hatchery chinook into the Cowichan River as fry ( 3 g ) and as presmolts ( 6 g ).

Enhanced contribution to total chinook return

Figure 9. Natural and enhanced contribution to the Cowichan River chinook escapement for the years 1982 to 2001.

[^0]:    ${ }^{1}$ Ketchum Manufacturing Ltd., Ottawa, Canada.

[^1]:    ${ }^{1}$ Barry Cordecedo (Salmonid Enhancement Program) provided numbers on broodstock collection from 1981 to 1987. The broodstock numbers provided included jacks, but no reliable records were kept. It was estimated that for most years about 10 to 15 jacks were collected. These estimates were subtracted from the broodstock numbers resulting in an estimate of the number of adult chinook removed from the system.
    ${ }^{2}$ In addition, 284 males were removed for broodstock but later returned to the river.
