# Canadian Manuscript Report of Fisheries and Aquatic Sciences 2655 

Canadian Manuscript Report of Fisheries and Aquatic Sciences

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers $1-900$ in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551.

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport manuscrit canadien des sciences halieutiques et aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques ques qui constituent une contribution aux connaissances actuelles; mais qui traitent de problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports manuscrits sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annual des publications scientifiques et techniques du Ministère.

Les numéros 1 à 900 de cette série ont été publiés à titre de manuscrits (série biologique) de l'Office de biologie du Canada, et après le changement de la désignation de cet organisme par décret du Parlement, en 1937, ont été classés comme manuscrits (série biologique) de l'Office des recherches sur les pêcheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de rapports manuscrits de l'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

Les rapports manuscrits sont produits a l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

#### Abstract

Nagtegaal, D.A., E.W. Carter, N.K. Hop Wo, and K.E. Jones. 2004. Adult chinook escapement assessment conducted on the Cowichan River during 2002. Can. Manuscr. Rep. Fish. Aquat. Sci. 2655: 49 p.

In 2002, the Biological Sciences Branch, Pacific Biological Station, continued a study of chinook salmon (Oncorhynchus tshawytscha) productivity in the Cowichan River. This in-depth escapement assessment project has been in place since 1988. Major components of this study included: i) enumerating spawners and total return, ii) estimating First Nations food fish catch, iii) recording hatchery broodstock removals, and iv) collecting biological, environmental and codedwire tag data. Population estimates for adult and jack chinook were determined based on the fence count since this was considered to be the most accurate enumeration method. A carcass markrecapture study was conducted on the spawning grounds to augment the collection of biological data and to supplement the fence count population estimate. The total return of adult chinook to the Cowichan River was estimated to be 5,785 fish of which 2,505 spawned naturally in the river. A total of 1,480 adult chinook were collected for hatchery broodstock, 1,500 adults were estimated as captured in the First Nations food fishery and approximately 300 adults were lost to seal predation.

## RÉSUMÉ

Nagtegaal, D.A., E.W. Carter, N.K. Hop Wo, and K.E. Jones. 2004. Adult chinook escapement assessment conducted on the Cowichan River during 2002. Can. Manuscr. Rep. Fish. Aquat. Sci. 2655: 49 p.

En 2002, la Direction des sciences biologiques de la Station biologique du Pacifique a poursuivi dans la rivière Cowichan l'étude sur la productivité du saumon quinnat (Oncorhynchus tshawytscha), un projet d'évaluation approfondie de l'échappée, lancée en 1988. Cette étude comporte les principaux éléments suivants : i) dénombrement des géniteurs et de la remonte totale, ii) estimation du volume des prises autochtones à des fins alimentaires; iii) consignation des prélèvements de géniteurs d'élevage et iv) collecte de données biologiques et environnementales et de données de micromarques magnétisées codées. Les effectifs de quinnats adultes et unibermarins sont estimés à partir des données de barrière de dénombrement étant donné que cette méthode de dénombrement est considérée comme étant la plus précise. Des carcasses de saumons étiquetés sont récupérés dans les frayères de sorte à enrichir les données biologiques et améliorer l'estimation des effectifs fondée sur les données de barrière de dénombrement. La remonte totale de quinnats adultes dans la Cowichan en 2002 a été estimée comme se chiffrant à 5785 poissons, dont 2505 ont frayé naturellement dans la rivière. Un total de 1480 géniteurs ont été prélevés aux fins d'élevage et, d'après les estimations, 1500 adultes ont été capturés dans le cadre de la pêche autochtone à des fins alimentaires et 300 autres ont été la proie des phoques.

## INTRODUCTION

Chinook stocks are invaluable to both commercial and recreational fisheries of the Pacific Northwest (Collicut and Shardlow 1995). In spite of protective measures, chinook salmon abundance has continued to decline. This trend has resulted in the recent addition of chinook to the list of threatened and endangered species in the United States (Waples 1991). The problem of declining stocks is similarly serious on the West Coast of Canada, and has potential ramifications regarding the sustainability of British Columbia's fishing industry (Argue et al. 1983). Over the past several years, considerable interest has been focused on the chinook stocks of the southern portion of the Strait of Georgia due to the decline in these stocks and their importance to local fisheries (Farlinger et al. 1990). The Stock Assessment Division, Pacific Biological Station, initiated a study of chinook productivity to assess rebuilding strategies and to evaluate the effects of harvest management policies for these stocks. In the fall of 1988, a study was implemented on Cowichan River chinook with additional information collected from the Squamish and Nanaimo River stocks. These three stocks within the framework of the Pacific Salmon Treaty between Canada and the United States were identified as exploitation and escapement indicators and deemed to represent the status of all lower Georgia Strait chinook stocks (PSC 1990). Since then, due to logistical reasons the Squamish River system was dropped as an indicator, and in 2002 the Nanaimo River system was dropped as well.

Major hatchery production of chinook on the Cowichan River began in 1980 (Cross et al. 1991). Chinook fry releases have increased from 64,681 in 1980 to 3.23 million in 2002. Coded-wire tag (CWT) releases also began in 1980 and by 2002 approximately $7 \%$ of the chinook released carried coded-wire tags.

This report presents the results of the study completed during 2002. The objectives included:

1. enumerating chinook, coho and chum salmon migrating past the counting fence,
2. estimating First Nations food fishery catch,
3. recording hatchery broodstock removals,
4. collecting biological data and sampling coded-wire tag recoveries,
5. implementing a carcass mark-recapture study for both adult and jack chinook, and
6. monitoring results of the Cowichan River Water Management Plan.

## METHODOLOGY

A detailed description of the methodology is presented in Nagtegaal et al. (1994b). A summary of the methods is presented below along with any changes that were incorporated during the 2002 study.

## STUDY AREA

The Cowichan River watershed is located on the Southeast coast of Vancouver Island and drains an area totalling $826 \mathrm{~km}^{2}$. The Cowichan River system includes Cowichan, Bear, Mesachie, Somenos, and Quamichan lakes. Cowichan Lake ( $62 \mathrm{~km}^{2}$ ), the largest of the five lakes, is situated approximately 50 km west of the Cowichan Bay estuary. Discharge from a flow control dam situated at the outlet of Cowichan Lake ranges from 7 to $326 \mathrm{~m}^{3} / \mathrm{s}$, and averages 44.9 $\mathrm{m}^{3} / \mathrm{s}$ (Feilden and Holtby 1987). A total of 26 tributaries drain into the Cowichan River. The largest of these is the Koksilah River, which intersects the mainstem of the Cowichan River approximately 2.5 km upstream of the estuary. The Cowichan River watershed system is a typical Vancouver Island and coastal British Columbia stream in which maximum flows occur during winter months due to heavy rainfall (McDougall 1985).

The Cowichan River supports many salmonid species including chinook (Oncorhynchus tshawytscha), coho (Oncorhynchus kisutch), chum (Oncorhynchus keta), sockeye (Oncorhynchus nerka), and pink (Oncorhynchus gorbuscha) salmon; as well as cutthroat trout (Oncorhynchus clarki), steelhead trout (Oncorhynchus mykiss), kokanee salmon (Oncorhynchus nerka), and dolly varden char (Salvelinus malma). Attempts have been made to introduce several other species including: atlantic salmon (Salmo salar), brown trout (Salmo trutta), and brook trout (Salvelinus fontinalis) (Perrin et al. 1988). The salmonids of the Cowichan River support several vital fisheries, which include a First Nations food fishery, tidal sport fishery, and a commercial ocean fishery.

## ENUMERATION FENCE

The counting fence was placed upstream of the city of Duncan, in the same location as in previous years (Figure 1). The design incorporated a resistance board weir with a counting raceway (adjustable flashboard) and trap box adjacent to a counting tower equipped with floodlights. Counts were continuously recorded by 15 -minute interval for adult and jack chinook, adult and jack coho, and chum salmon. If identification was in doubt, fish were recorded as unknown. Water depth, temperature, water clarity, and weather condition were recorded three times per day. The fence was checked daily for any breaches and cleaned of leaves and other debris. Any removal of broodstock at the fence site by hatchery staff was recorded.

## Fence Enumeration Video

An underwater video camera was installed at the fence site in order to verify and provide an independent record of fish passing through the enumeration fence. Fish were recorded by species, with chinook sex and adipose fin status also being noted. Morphological features were used to help identify jack chinook from adult chinook.

## SWIM SURVEYS

In an effort to maintain consistency with historical data sets, swim surveys were conducted, in conjunction with Cowichan Tribes Aboriginal Fisheries Management (CTAF), to estimate the spawning population of chinook. Swims were made in the upper section of the river only (Figure 1) with counts extrapolated to the total system. Each survey was conducted by three experienced swimmers while one person in a canoe recorded the data. Each swimmer (one in the middle and one on each side of the river) counted the fish seen within their range of visibility. The three swimmers attempted to keep abreast as they approached each pool while the person in the canoe lagged behind within hailing distance. Counts were recorded by pool/riffle and then compiled by river section. To maintain consistency in counting procedures the same swim team was used for each survey whenever possible. Based on the historical distribution of spawners, swim counts were expanded by a factor of 3.4 to derive an estimate of total escapement (Nagtegaal et al. 1994a). This expansion factor was consistently applied to swim counts with no adjustments made for run timing or changes to spawner distribution. A final escapement estimate was then determined based on consultation with Fishery Officers using the swim counts in conjunction with other anecdotal information.

It was intended that the swim survey estimates remain independent of the fence count. However, even though fence counts were not passed on to the swim teams during the season, general trends in escapement numbers were known.

## FIRST NATIONS FOOD FISHERY

In 1990, a systematic approach was developed by the Cowichan Tribes Aboriginal Fisheries Management program to monitor the fishery more closely and to better estimate the First Nations food fish catch (Paige 1992, 1997). This approach involved recording catch and effort by management zone within the First Nations fishing boundaries (Figure 2). A crew of four observers patrolled the fishery on a daily basis and interviewed fishermen for numbers caught by area and total time spent fishing. In this way, weekly estimates of catch per unit effort (CPUE) were obtained. CPUE was adjusted for daily changes in fishing effort and differences in effort among fishing zones. These data were then extrapolated over time and area to estimate total catch by week and summed over all weeks to estimate the total catch for 2002.

$$
C A T C H \equiv \sum_{n}^{w=1} C P U E_{w} \times E F F O R T_{d}
$$

where $w$ refers to the time interval for catch (week), and $d$ refers to the time interval for effort (day). No confidence limits were calculated (Paige 1997).

For some years since 1988, an observer was employed to independently collect catch and biological data from the in-river First Nations fishery. Due to budget constraints no observers were employed from 1999-2001 and CTAF catch estimates could not be independently verified. However, in 2002 an independent observer was in place to enumerate the in-river First Nations fishing catches.

## BIOLOGICAL DATA

Biological data for chinook were collected from hatchery broodstock samples and from carcasses recovered on the spawning grounds. Data collected included sex, post orbital-hypural $(\mathrm{POH})$ length, and adipose fin status (present/absent). All chinook sampled from either the spawning grounds or hatchery broodstock were examined for the presence of a CWT using either a Northwest Marine Technology ${ }^{1}$ Handheld Wand Detector or a Northwest Marine Technology ${ }^{1}$ R9500 Tunnel Detector. All adipose fin clipped chinook and fish suspected of having a CWT had heads removed for decoding of coded-wire tags as well as scales obtained for age analysis. All chinook recovered on the spawning grounds were sampled and spawning condition was noted. Hatchery staff randomly collected biological data from approximately $25 \%$ of the chinook broodstock and from all chinook suspected of carrying a CWT.

## MARK-RECAPTURE

A mark-recapture program involving the tagging and subsequent recovery of chinook jack and adult carcasses was conducted on the spawning grounds. Crews consisting of two or three individuals surveyed the upper section of the river each day using an inflatable boat (Figure 1). All chinook carcasses encountered were individually tagged with a Ketchum ${ }^{2}$ aluminum sheep ear tag on the left operculum and immediately released in the same area as captured. Location of capture and release, tag number, spawning condition, POH length, sex, and adipose fin status (present or absent) were recorded for each carcass. Tag number and recovery location were recorded for all previously marked carcasses, which were then removed from the system.

The section of the river selected for the mark-recapture study is located above Skutz Falls and represents the area where the majority of chinook spawning has typically occurred. A 4.2 m pole with a gaff hook attached to the end was used to recover carcasses. Carcasses that ended up in deep pools were occasionally unable to be retrieved.

Mark-recapture estimates were generated using the Petersen model (Chapman modification) stratified by sex (Ricker 1975). Data were stratified to minimize the effects of differential tagging and tag recovery between sexes. This study follows the estimation procedure as outlined in previous reports (Nagtegaal et al. 1994a, 1994b, 1994c).

To determine the validity of the mark-recapture estimate, potential biases were assessed to test for violations of the assumptions inherent in the Petersen mark-recapture method (Ricker 1975; Seber 1982; Krebs 1989). Sex related bias in the application sample was examined by comparing the sex ratio of the marked versus the unmarked recoveries. Sex related bias in the recovery sample was assessed by comparing the sex ratio of recovered samples with unrecovered samples. Size bias in the application sample was examined by comparing lengths of marked versus unmarked recoveries. Size bias in the recovery sample was examined by comparing lengths of recovered and unrecovered tag samples. Statistical comparisons of length data were carried out using pooled variance Student's t-tests. Temporal bias in application samples was

[^0]assessed by stratifying sampling dates into approximately equal periods and comparing mark incidence among strata. Similarly, temporal bias in recovery samples was stratified by dates and the ratio of tagged recoveries to tags applied was compared. Statistical assessments of sex and period biases were carried out using Chi-square tests.

## WATER MANAGEMENT PLAN

Low flow and low water levels likely result in delayed fish movement and higher water temperatures which may potentially increase levels of diseases and parasites. During particularly low water levels the river flow can be increased with a controlled water release from the Lake Cowichan Weir. Discussions between NorskeCanada, Fisheries and Oceans Canada, Land and Water British Columbia, Cowichan River Hatchery, Cowichan Tribes and other user groups lead to a water management plan for the Cowichan River. This plan was committed to maintaining Cowichan River water levels for fish, First Nations and recreational users.

## POPULATION ESTIMATE

Chinook population estimates are based on fence data when enumeration conditions are good and when counts are deemed reliable. Before a final estimate is reached fence count data are adjusted by jack/adult ratios observed from spawning ground chinook recoveries and expanded by a further a $15 \%$ to account for chinook arriving prior to installation and after fence removal. Total run size is calculated by using adjusted fence count data, First Nations food fishery removals, hatchery broodstock removals and seal predation estimates. The mark-recapture estimate is used in years when fence count data are unreliable.

## RESULTS

## ENUMERATION FENCE

The enumeration fence was installed upstream from the City of Duncan at the traditional site (Figure 1) and was operational from September 3 to November 13. Water conditions were clear for most of the study with only four days noted as cloudy and four days as partially cloudy (Table 1). As a result, conditions were ideal for viewing fish migration past the counting tower and all counts are deemed to be reliable. A total of 2,745 chinook adults, 1,667 chinook jacks, 3,807 coho adults and 602 coho jacks were counted migrating past the enumeration fence. In addition, 79,952 chum and 160 unidentified fish were enumerated at the fence site (Table 1). Since there were no breaches of the fence during the project it was assumed that all fish migrating past the fence during the study period were enumerated.

In past years, chinook jacks have been prominent during the early segment of the return migration often matching adult chinook counts. In 2002, the proportion of jack chinook mirrored the overall temporal pattern of adult chinook migration past the fence (Table 1, Figures 3a, 3b).

The pattern of daily migration past the fence was examined by summarizing hourly counts throughout the program (Table 2). A major peak in migration for both adult and jack chinook occurred between 0600 and 1000 hrs . During this period, $33.4 \%$ of adult chinook and $30.3 \%$ of jack chinook moved past the fence site.

In past years, tower counts and species identification were verified on several occasions throughout the run by capturing all fish migrating past the fence during one counting segment in the upstream trap box. With the addition of video monitoring, this practise was not carried out in 2002.

## Video Enumeration Data

During the 2002 chinook assessment over 130 hours of fence enumeration video was recorded. Fence video was recorded between 11 September and 08 November during various time intervals ranging from one hour to 4.5 hour segments. Video data were recorded by species with chinook being differentiated by sex as well as adipose fin clip status. Video data were used in comparing species identification, jack/adult ratios and adipose clipped mark rates with fence enumeration data as well as with mark-recapture results. There were 35 corresponding time periods between video data and fence data from which species and jack/adult comparisons could be made.

During corresponding time periods, video data enumerated $4.3 \%$ more fish and $4.8 \%$ less chinook than were recorded at the enumeration fence. Of the 829 chinook identified by video analysis during this period, 395 were adult, 134 were jack and 297 were unknown sex chinook. Fence observer data from corresponding periods yielded 868 chinook of which 523 were adult and 345 were jack chinook. Video analysis identified $74.7 \%$ of chinook as adults compared with $60.3 \%$ from fence records. Video data also provided chinook mark rates with $3.8 \%$ of male chinook, $5.5 \%$ of female chinook and $1.0 \%$ of jack chinook missing adipose fins.

## SWIM SURVEYS

A summary of all visual surveys conducted by DFO Fishery Officers and by the Cowichan Tribes Aboriginal Fisheries Management group from 1981 to 2002 is presented in Table 3. Total escapement estimates for each year include adult chinook only. In 2002, only one swim survey was conducted on October 23 in the upper section of the river between Road Pool and Train Trestle (Figure 1). The survey was completed during low river flow and good visibility. Adult chinook counts were 418 and this number was expanded to an estimate of 1,421 fish.

## FIRST NATIONS FOOD FISHERY

Historical estimates of the number of chinook captured in the in-river First Nations food fishery are presented in Table 4 and Figure 4. The 2002 catch estimate of 1,500 adults and zero jacks was determined by the Cowichan Tribes Aboriginal Fisheries Management group (Figure
2). An independent DFO fisheries observer estimated First Nations food fishery catches of approximately 1,700 adult chinook. Also, if non-catch mortalities (fish that escaped capture but died before spawning due to fishery induced injuries) were included, the impact of the fishery would likely be more significant.

## HATCHERY COMPONENT

Between September 23 and October 21, Cowichan River Hatchery staff collected 636 male and 622 female chinook from the river downstream of the fence. In addition, 86 male and 136 female chinook were collected upstream of the fence (Table 5). The total number of chinook removed from the river for hatchery broodstock was within the range required for hatchery production (Table 6). Age analysis of scale samples revealed the majority of chinook used in hatchery broodstock were three or four year olds, $63.8 \%$ and $35.6 \%$, respectively (Table 7).

## BIOLOGICAL DATA

A total of 60 male, 91 female and 102 jack chinook carcasses were recovered on the spawning grounds and measured for post orbital-hypural length (Table 8). The length of adult male chinook carcasses ranged from 37.3 to 76.6 cm and averaged 59.4 cm , while female carcasses ranged from 49.4 to 83.0 cm and averaged 66.8 cm . Jack chinook carcasses ranged in length from 28.0 to 67.2 cm and averaged 36.9 cm . A total of zero male, one female and two jack chinook (representing $0.0,1.1 \%$ and $2.0 \%$, respectively) recovered from the spawning grounds had clipped adipose fins (Table 8). The majority of adult chinook were three or four years old ( $46.7 \%$ and $46.7 \%$, respectively) while most fish identified as jack chinook ( $90.4 \%$ ) were two years old (Table 9).

A total of 65 male, 111 female and zero jack chinook were randomly collected from broodstock sampling (Table 10). Post orbital-hypural length measurements of male chinook ranged from 50.5 to 71.8 cm and averaged 58.9 cm while female chinook ranged from 50.6 to 81.0 cm and averaged 64.5 cm . One male and nine female chinook ( $1.5 \%$ and $8.1 \%$, respectively) were missing adipose fins (Table 10).

No statistically significant difference was present when the lengths of male and female chinook carcasses recovered on the spawning grounds were compared to those samples obtained from hatchery broodstock (Student's $t$-test: $\mathbf{t}=0.392 ; p<0.01$ and $t=2.589 ; p<0.01$, for males and females respectively).

Analysis revealed no statistically significant difference in the adipose fin clip rate between female and male chinook carcasses recovered on the spawning grounds and those recovered from hatchery broodstock (Chi-square $=5.221 ; \mathrm{p}<0.01$ and Chi-square $=0.931$; $\mathrm{p}<0.01$, males and females respectively). A comparison between adipose fin clip rates obtained from fence video data and fall run hatchery broodstock also yielded no statistical differences (Chi-square $=0.859 ; p<0.01$ and Chi-square $=0.878 ; \mathrm{p}<0.01$, for males and females respectively). Furthermore an adipose clip rate comparison between fence video data and
spawning ground chinook provided no statistical differences (Chi-square $=2.373 ; \mathrm{p}<0.01$, Chisquare $=3.096, \mathrm{p}<0.01$, Chi-square $=0.544 ; \mathrm{p}<0.01$, for males, females and jacks respectively).

Five chinook heads were collected from the spawning grounds for CWT analysis. Of the two adipose clipped chinook analysed, no CWT's were found. Two coded-wire tags were recovered from the remaining three adipose present chinook carcasses sampled. Both CWT chinook were adult females from the 1999 brood year and were released as part of the upper Cowichan River (late) release strategy (Table 11). A summary of all chinook releases from the Cowichan River Hatchery since 1979 is presented in Table 12.

## ENVIRONMENTAL INFORMATION

Environmental data collected at the fence site included water temperature, visibility and water depth (Table 1). Water temperature was generally higher at the start of the study and decreased until November (Figure 3a). Water temperature over this period ranged from 6 to $20^{\circ} \mathrm{C}$ and averaged $13.5^{\circ} \mathrm{C}$. Water depth at the fence site was consistently low with one peak on October 4. During the second week of November the water level continued to rise until fence removal (Figure 3b). Water depth over the study period ranged from 49 to 77 cm and averaged 54.2 cm . Water clarity was recorded in the form of a visibility code. For the majority of the study, visibility at the fence site was clear. Only four days were recorded as moderately cloudy (code 1-2) and four days as cloudy (Table 1).

River discharge was recorded at the Water Survey Canada station below the Island Highway Bridge in the City of Duncan (Table 13, Figure 1). River discharge during the course of the 2002 study was lower then the 30-year average from September to December (Figure 5).

## CARCASS MARK-RECAPTURE

Between November 4 and November 29 a total of 60 male, 91 female and 102 jack chinook carcasses were tagged and released in the upper Cowichan River (Table 14a, 14b). Of the 31 carcasses recovered with tags, $7(22.6 \%)$ were male, $13(41.9 \%)$ were female, and 11 (35.5\%) were jack chinook. Using the Petersen estimator, the adult chinook spawning ground population size was determined to be 1,245 fish ( $95 \%$ CI: 757 to 1,733 ), while the jack chinook population was estimated to be 979 fish ( $95 \%$ CI: 475 to 1,482 ) (Table 15).

## Potential Biases

The assessment of sampling selectivity had several potential biases in the carcass markrecapture study.

1. Temporal bias: Temporal bias in the tagging sample was examined by stratifying the mark incident rate into four recovery periods (Table 16). There was a significant temporal bias in the application sample for both male and female adult chinook when the data were stratified into
four equal recovery periods (Chi-square $=13.38 ; p<0.01$ and Chi-square $=14.76 ; p<0.01$, for males and females, respectively).

Temporal bias in the recovery sample was analysed by stratifying the recovery rates into four application periods (Table 17). A statistical difference in the recovery sample for both male and female adult chinook was observed (Chi-square $=26.70 ; \mathrm{p}<0.01$ and Chi-square $=20.55$; $\mathrm{p}<0.01$, males and females, respectively).
2. Fish Sex: Sex related bias was examined by comparing the sex ratio of the marked and unmarked spawning ground recoveries by application sample and by recovery sample. No sex related bias was evident when comparing male and female chinook populations (Chi-square $=0.22 ; \mathrm{p}<0.01$ and Chi-square $=0.17 ; \mathrm{p}<0.01$, application sample and recovery sample, respectively) (Table 18). When jack chinook were included in the application and recovery samples no significant bias was apparent (Chi-square $=0.57 ; \mathrm{p}<0.01$, and Chi-square $=0.45$; $\mathrm{p}<0.01$, application sample and recovery sample, respectively) (Table 19).
3. Size bias: Size related bias was examined by comparing the POH mean lengths of unrecovered marked chinook and recaptured chinook by sex. No size bias was evident in the recovery sample for adult male, adult female and jack chinook (Student's $t$-test: $t=2.310 ; p<0.01$, $\mathrm{t}=0.762 ; \mathrm{p}<0.01$, and $\mathrm{t}=0.279 ; \mathrm{p}<0.01$, for males, females and jacks respectively).
3. Location bias: Spatial bias was not examined due to insufficient sample size in the middle section of the river.

## WATER MANAGEMENT PLAN

Cowichan River water releases started on October 02 and finished on October 08, 2002. Water was released from the Lake Cowichan Weir and increased gradually from $250 \mathrm{ft}^{3} / \mathrm{s}(7.1$ $\left.\mathrm{m}^{3} / \mathrm{s}\right)$ to $450 \mathrm{ft}^{3} / \mathrm{s}\left(12.7 \mathrm{~m}^{3} / \mathrm{s}\right)$ on October 02 and from $450 \mathrm{ft}^{3} / \mathrm{s}\left(12.7 \mathrm{~m}^{3} / \mathrm{s}\right)$ to $650 \mathrm{ft}^{3} / \mathrm{s}\left(18.4 \mathrm{~m}^{3} / \mathrm{s}\right)$ on October 03. Between October 03 and October 06 flow rates remained at $650 \mathrm{ft}^{3} / \mathrm{s}\left(18.4 \mathrm{~m}^{3} / \mathrm{s}\right)$ with flows reduced to $450 \mathrm{ft}^{3} / \mathrm{s}\left(12.7 \mathrm{~m}^{3} / \mathrm{s}\right)$ on October 07 . Flows were further reduced to 250 $\mathrm{ft}^{3} / \mathrm{s}\left(7.1 \mathrm{~m}^{3} / \mathrm{s}\right)$ on October 08. During this period, chinook upstream migration peaked on October 03 with 534 adults and 264 jacks enumerated at the fence site (Figure 3b).

## POPULATION ESTIMATE

Escapement and total return estimates for 2002 were determined using fence count data since these are considered to be the most accurate enumeration method. However, after reviewing both spawning ground carcass recovery and hatchery broodstock collection data, it became evident that the chinook fence count did not accurately reflect the true jack to adult ratio. Analysing the lengths of jack and adult chinook with the traditionally accepted jack designated length of 450 mm revealed an overlapping of age groups (Figure 6). As a result, the spawning ground carcass recovery data were utilized to apportion the total chinook fence count with a more reflective ratio of jack and adult chinook within the population. This was accomplished by
comparing age data with length data to calculate the proportion of two year old jack chinook with lengths greater then $450 \mathrm{~mm}(4.5 \%)$ and the proportion of three year old or greater adult chinook with lengths of 450 mm or less ( $6.3 \%$ ). The fence count data were then adjusted by these proportions yielding total chinook fence counts of 2,727 adults and 1,685 jacks. No adjustments were made to account for chinook arriving prior to installation or after fence removal leaving the final estimate of adult chinook migrating past the fence site at 2,727 .

The number of naturally spawning adult chinook in the Cowichan River during 2002 was determined to be the fence count minus any broodstock removals or First Nations fishery catch from areas above the fence. Following this methodology, the total number of adult chinook spawning in the Cowichan River was estimated to be 2,505 fish (Table 20).

The total return of adult chinook to the Cowichan River was determined to be the sum of the total fence count with the addition of broodstock removals and the First Nations fishery catch. A further 300 fish were added to this total to account for chinook lost to seal predation in the Cowichan estuary (see discussion for details). Following this methodology, the total return of adult chinook to the Cowichan River was estimated to be 5,785 fish (Table 20).

## DISCUSSION

## ENUMERATION FENCE

The floating fence design functioned well in the flow conditions that existed in the lower Cowichan River during the fall of 2002. While the fence was intended to be self-cleaning, field staff were required to regularly remove leafy debris from the fence panels during periods of heavy rain and related high flows. During such periods, fence panels became over burdened and could not remain afloat without the removal of debris. While this difficulty has been observed in other fence studies (Cousens et al. 1982, Johnston et al. 1986) it is likely that the extent of the problem varies by year and location.

During many of the past monitoring studies, high flows have caused fence damage or forced early removal resulting in incomplete fence counts. During the current study, the enumeration fence was operational throughout the monitoring period and a complete count of all fish passing the site was attained. Past studies have indicated that approximately $15 \%$ of the chinook run arrives after October 30 (Nagtegaal and Carter 1998) and this proportion is usually incorporated into the final estimate of chinook migration past the fence. In the current study, no additional expansion was made to the fence enumeration estimate to adjust for an incomplete fence. Furthermore, the 2002 study enumerated $24 \%$ of total chinook fence counts after October $30,9 \%$ greater than the previously noted $15 \%$.

Several of the past fence enumeration studies conducted on the Cowichan River have noted the mis-identification of jack versus adult chinook by observers monitoring the migration of chinook past the fence (Nagtegaal and Carter 1998, 2000). While trap box verifications of observer counts were not carried out in 2002, it became clear from both spawning ground and hatchery broodstock data that the adult to jack ratio recorded at the fence was not reflective of the
true population parameters. Since there were a number of jack chinook at the upper end of the size distribution, it appears as if some of these fish were counted as adults. This seems likely as it would be very difficult to determine the size of a moving fish to within a few centimetres when viewing them from a counting tower well above the river. As a result, the total chinook fence count was adjusted by the ratio of adult and jack chinook sampled during the spawning ground carcass recovery.

## Video Enumeration Data

Video data from the fence site provided an independent audit of species identification as well as adult and jack chinook enumeration. Only a partial comparison was made between the video and the observer fence data due to the camera not operating the entire length of the enumeration study. Chinook counts and total fish counts deviated less than $5 \%$ from fence observer data while adult and jack ratios differed by more than $14 \%$. This variation in adult and jack ratios may be due to methodological differences as video analysis based sex differentiation on morphology and fence observers used length to define a jack chinook. The tendency for video analysis to record difficult to identify chinook as an unknown sex ( $36.0 \%$ ) may skew jack and adult ratios obtained from video data.

## SWIM SURVEYS

Among the biases typically associated with swim surveys, the extrapolation of actual swim counts to total estimates warrants some consideration (Burns unpubl.). Assumptions concerning the distribution of chinook in the river at the time of the survey are the basis for expanding these counts to estimate total escapement (T. Fields, 230 Underwood St., Duncan, B.C. V9L-3X3; pers. comm.). In 1991, it became apparent that during high water flow conditions in early fall, expansions based on the swim survey results overestimated total escapement (Nagtegaal et al. 1994b). The results of the 1992 swim surveys support the hypothesis that during low water flow conditions in late fall, expansions based on swim survey results underestimate the number of spawners (Nagtegaal et al. 1994c). Low flow conditions lead to underestimation of spawners because the distribution of fish in the river is affected by flow. Generally, in low water years, not as many fish make it to the traditional spawning areas above Skutz Falls. The expansion of swim surveys conducted in the upper area alone tends to underestimate the number of fish. Conversely, during high water years most of the fish make it above Skutz Falls so the expansion factor tends to overestimate the number of fish.

The 2002 swim survey expanded estimate of 1,421 is considerably lower than the natural spawning estimate of 2,505 adult chinook. This could partially be explained by low river flows, which would result in an under-estimation of adult chinook. It should also be noted that only one swim survey was conducted in one section of the river therefore conclusions from these data are limited.

## FIRST NATIONS FOOD FISHERY

Catch estimation procedures developed by the Cowichan Tribes Aboriginal Fisheries Management unit have not been assessed by stock assessment staff. As a result, no comments can be made regarding the methodologies used. Discussions involving CTAF and DFO resulted in a final First Nations food fishing estimate of 1,500 adult chinook. The current food fishing estimate of 1,500 chinook was an increase over 2001 estimates (Table 4).

## BIOLOGICAL DATA

Male and female chinook collected by the hatchery for broodstock were not statistically different in length than the carcasses recovered on the spawning ground. This suggests the retrieval method used at the spawning grounds and the beach seine method used in broodstock capture were both relatively non-selective for size.

Statistical analysis revealed no difference in the adipose fin clipped rates of both male and female chinook collected from the spawning grounds or those collected for hatchery broodstock. An adipose clip rate comparison between fence video analysis and both hatchery broodstock and spawning grounds sampled chinook also yielded no statistical differences. This suggests adipose fin status did not bias fish collection at either the spawning grounds or at the hatchery.

The two CWT adipose present chinook obtained from the spawning grounds are part of a double index tagging (DIT) study taking place in the Cowichan River. The DIT study's purpose is to investigate a potential difference in survival rates between clipped fish with CWT's and unclipped fish with CWT's. During the DIT study both adipose present and adipose clipped fish are tagged with CWT's and released from the Cowichan River Hatchery. DIT study information may be used in deciding whether adipose clipping hatchery fish is a viable option in hatchery only retention fisheries and to assess if differential mortality occurs between adipose clipped and non-adipose clipped fish.

## MARK-RECAPTURE

The carcass mark-recapture portion of the Cowichan River chinook stock assessment project was implemented many years ago for several reasons. First, since handling fish at the fence site caused significant migration delays this practice was abandoned to ensure chinook reached the spawning grounds without undue stress. While length, age and sex data were collected by hatchery staff during broodstock capture, these data were not consistently representative of the spawning population. The sampling of carcasses from the spawning ground provided an additional source of biological data, which when pooled with the hatchery sample was more representative of the true population. Second, the recovery of coded-wire tags from hatchery broodstock did not provide an adequate sample size for a rigorous assessment. Spawning ground carcass recoveries yield additional coded-wire tagged fish. Finally, since high flows in past years have caused fence damage that resulted in incomplete enumeration of spawners, an additional method of providing a population estimate was required.

Population estimates for adult and jack chinook were determined using the pooled Petersen estimator. Since the true population size was not known, a direct measure of the accuracy of the estimates was not possible. However, an assessment of the underlying assumptions of equal probability of capture, simple random recovery sampling and complete mixing can usually be made by testing recovery and application samples for temporal, spatial, sex and size related biases (Schubert 2000). To carry out most of the bias assessments, different gear types must be utilized for capturing the tag application and the recovery samples. In the current study, the spawning ground carcass recovery was used to obtain both samples thus limiting the ability to assess sample biases.

The assessment of sampling selectivity revealed several biases in the carcass markrecapture study. There was a significant temporal bias in the application sample for both male and female chinook. The assessment revealed that tag incidence was very low during the early period and higher during the last period. This is likely due to the nature of the carcass recovery study, since tagging and recovery were concurrent activities. As a result, there were very few tagged carcasses available for recovery in the early period and as the number of tags in the population accumulated towards the end of the study, the tag incidence in the later periods was much higher. There was also a temporal bias in the recovery sample for males and females. Once again this bias was primarily due to the nature of the study since more tagged fish were available for recapture during the later periods of the study.

No sex related bias was evident in the application or recovery samples for adult chinook or when jack chinook were included in the assessment. In the past years jack chinook were recovered proportionally less than adult chinook. This was likely due to the size difference between adult and jack chinook, which effects the way carcasses behave in the river. Since jack carcasses are much smaller, they are more easily flushed out of the recovery area by small increases in river flow. However, during the course of the November 2002 spawning ground recovery a large increase in river flow was noted with initial flow rates of $5.1 \mathrm{~m}^{3} / \mathrm{s}$ rising to a peak of $178.7 \mathrm{~m}^{3} / \mathrm{s}$. This sharp increase in flow could attribute to various sizes of carcasses being washed away at an equal rate.

Size bias testing did not provide an assessment of the size selectivity of the sampling method since both application and recovery samples were obtained using the same method. Rather, the size bias assessment provided an evaluation of the recoverability, based on size, of tagged carcasses that were redistributed back into the river after tagging. Testing revealed that there was no size bias for male, female, or jack chinook.

Bias associated with location was not tested due to insufficient sample size in the middle section of the river. This may have been due to cloudy water conditions making carcass recoveries difficult, although some carcasses were found along the sides of the river. Erosion of clay banks, which exist in this segment of the river, cause the water to be very cloudy and substantially reduces water visibility. Conditions for recovering carcasses further deteriorate as water flow increases. Although location bias could not be tested, marked fish have been recovered by sports fisherman well downstream of the study area. This suggests some tagged specimens were not available for recapture and were probably flushed out of the study area due to
higher than average water flow (Figure 5). A reduction in the ability to recapture tagged carcasses would contribute to an overestimation of the actual chinook population.

The detection of sampling biases usually results in the use of a stratified estimator; however, Schubert (2000) compared the performance of several mark-recapture population estimators for a sockeye salmon population of known abundance and concluded that the pooled Petersen estimator was less biased and preferred over stratified estimators. In that study, the Schaeffer estimator would not improve accuracy and it was recommended that the method be abandoned for use in population estimation. Also, it was determined that while the maximum likelihood Darroch estimator could potentially improve accuracy there was no obvious way of selecting between accurate and highly biased estimates. Parken and Atagi (2000) found that pooled and stratified estimators of Nass River summer steelhead produced similar escapement estimates but that the pooled estimator was more precise and had less statistical bias than the stratified estimator. These findings highlight the robust nature of the pooled Petersen estimator and suggest that its usage in determining population abundance from mark-recapture data is generally appropriate under a wide range of circumstances.

## WATER MANAGEMENT PLAN

The scheduled water release during October 02 and October 08 was gradually increased and decreased in order to minimise the effects associated with a sudden rise in river levels. This release resulted in a migration peak as fish holding below the enumeration fence swam upstream during this brief period of increased river discharge.

## SEAL PREDATION

Although seal predation was not directly assessed in this study, it is worthwhile to examine the impact seals have on chinook in Cowichan Bay. In 1988, the number of seals gradually increased from a low of 30 in April to a peak of about 100 in December. According to Olesiuk et al. (1990) harbour seals consume an estimated 9 tonnes of salmon annually in Cowichan Bay. An estimated $23 \%$ (September) to $48 \%$ (November) of the harbour seals' diet in Cowichan Bay was comprised of salmon (Bigg et al. 1990). Based on these data, consumption of chinook salmon could potentially range from 100 to 500 adults. These data were collected in 1988 when low flows in the Cowichan River persisted until the end of October. Predation likely increases the longer chinook salmon remain in the estuary waiting for high water to allow upstream migration. While low flow conditions occurred during September to November 2002, Fishery Officers observations indicated that seal and sea lion populations have remained constant for the last couple of years in Cowichan Bay. As a result, predation on chinook was estimated to be approximately 300 adults.

Fishery Officers also noted a pod of killer whales feeding in Cowichan Bay for approximately 24 hours. Their affect on chinook populations could not accurately be assessed.

## POPULATION ESTIMATE

The 2002 Cowichan River chinook population estimate was based on the enumeration fence count. Low and moderate river flows allowed the fence to remain in place without significant breaches for the duration of the study and it was felt that a near complete census was attained. The estimated number of natural spawning adult chinook migrating past the fence site of 2,505 was above the $95 \%$ confidence limits of the $757-1,733$ adult chinook mark-recapture estimate. This result is consistent with past projects (Nagtegaal and Carter 1998, 2000) which have fence estimates above mark-recapture estimates. Since the mark-recapture study was conducted in the upper river only (the main spawning area) any chinook that spawned in other areas of the watershed were not included, therefore this estimate would not include all chinook migrating past the fence.

The estimated number of adult spawners was the third lowest since 1975, below the period average of 5,651 and well below the revised escapement goal of 7,400 (Riddell et al. 2000) (Table 20, Figure 7). Hatchery releases of chinook fry were over 2.5 million for both 1998 and 1999 brood years (Figure 8). The enhanced contribution was calculated to be $78.6 \%$ of the total adult chinook return. This estimate is thought to be biased high due to the small number of carcasses recovered in the mark-recapture portion of this study coupled with large expansion factors for marked to unmarked fry release ratios. Hatchery and natural contributions for Cowichan River chinook escapement are summarized by year in Figure 9. The total chinook estimate of 5,785 was below the period average of 7,232 (Table 20).

## ACKNOWLEDGEMENTS

We would like to thank Stefan Deleeuw, James Patterson, Phil Joe, Candace Boyle, Dave Burton, Ashley Pifko, Frank Sutherland, Chad Stewart, Shawn Stenhouse, and Doug August for their involvement in the implementation of the enumeration fence, collection of migration and biological data. We thank W. Jansen and E. Teskey, Fisheries and Oceans Canada Fishery Officers stationed in Duncan, for their helpful assistance. We thank the Cowichan Tribes Fisheries Management Unit, in particular Wayne Paige and Wayne Paige Jr. for their cooperation and assistance in acquiring First Nations food fishery data and swim survey results. We thank Don Elliot, manager of the Cowichan River Hatchery, for providing broodstock capture and biosampling data. We thank the conscientious sport fishers who returned the Ketchum tags from the chinook they caught in the Cowichan River. We thank the City of Duncan for allowing us to use their access road to the counting fence site and granting us storage space, power and water from their pumphouse facility. We thank F. Voysey, from Fisheries and Oceans Canada, W. Van Bruggen, the Regional Water Manager for British Columbia as well as M. Vessey and G. Kissack from NorskeCanada for co-ordinating the water release management plan for the Cowichan River.

Table 3. (continued)

${ }^{1}$ S - Swim survey, H - Helicopter survey, F - boat survey
${ }^{2}$ Refer to Figure 1.
${ }^{3}$ Total escapement estimate for adult chinook.
${ }^{4} 516$ chinook carcasses were counted in this total.
${ }^{5} 28$ chinook carcasses were counted in this total.
${ }^{6}$ Swim surveys conducted by Cowichan Tribes River Management Unit,
total escapement determined by Fishery officers.
${ }^{7}$ Adult population estimate based on swim survey records was not feasible
due to extremely low water conditions during swim survey.
${ }^{8}$ Swim survey took place in the lower Cowichan River from Black Bridge to
Green Point (Figure 2).

${ }^{1}$ Includes chinook caught in both the spear fishery and the in-river gillnet fishery.
${ }^{2}$ Since 1988, data has been collected by the Cowichan Tribes River Management unit. Prior to 1988, data were collected by local Fishery Officers.
${ }^{3}$ Estimates for jack chinook were not provided in 1997, 1998 and 2000.

${ }^{1}$ Barry Cordecedo (Salmonid Enhancement Program) provided numbers on broodstock collection from 1981 to 1987 . The broodstock numbers provided included jacks, but no reliable records were kept. It was estimated that for most years about 10 to 15 jacks were collected. These estimates were subtracted from the broodstock numbers resulting in an estimate of the number of adult chinook removed from the system.
${ }^{2}$ In addition, 284 males were removed for broodstock but later returned to the river.

Table 7. Summary of age by sex for Cowichan River chinook collected from hatchery broodstock during 2002.

| Age | Male |  | Female |  | Total Adult |  | Jack |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

${ }^{1}$ Cowichan River Hatchery release strategies for chinook:
Upper Cowichan River (late): raised to pre-smolt size ( $5-6 \mathrm{~g}$ ) prior to release approximately 3 km below the weir in May.
Upper Cowichan River (early): raised to fry ( 3 g ) prior to release approximately 3 km below the weir in early April.
Cowichan Lake Pen: raised to pre-smolt size (5-6 g) prior to release just above the weir in May.
Hatchery (late): raised to pre-smolt size ( $5-6 \mathrm{~g}$ ) prior to release at the hatchery in May.
Seapen: raised to smolt size $(6+\mathrm{g})$ prior to release from the netpens in Cowichan Bay in early June.

Table 13. Daily Cowichan River discharge ${ }^{1}\left(\mathrm{~m}^{3} / \mathrm{s}\right)$ during $2002^{2}$.

| 2000 | $5109{ }^{5}$ | 1529 | 89 | $7027{ }^{4}$ |
| 2001 | $3282{ }^{5}$ | 1732 | 918 | $6232{ }^{4}$ |
| 2002 | $2505{ }^{5}$ | 1480 | 1500 | $5785{ }^{4}$ |

${ }^{1}$ For the years 1989 to the present, the number of natural spawners was calculated as the number of adults recorded at the fence minus the adults removed for broodstock above the fence. In years when fence counts were incomplete, the cumulative run timing curve was used to expand the count.
${ }^{2}$ This number is the total broodstock removed and may include some jacks.
${ }^{3}$ Due to early flooding, estimate is based on expansion of swim surveys and weir counts.
${ }^{4}$ Includes an estimated 300 chinook lost to seal predation in the Cowichan estuary.
${ }^{5}$ For the years 2000 to the present, the adult fence count totals used in calculating natural spawners was adjusted using jack/adult ratios obtained from the spawning grounds.

Figure 1. Cowichan River survey areas.

## Swim survey locations were:

> 1 - Bird House Pool
> 2 - Road Pool
> 3 - Train Trestle (mile 70.2)
> 4 - Old Pick-up Site
> 5 - Maple Tree
> 6 - Three Firs Pool
> 7 - Skutz Falls
> 8 - Marie Canyon
> 9 - Bible Camp
> 10 - Cowichan Side channel
> 11 - Sandy Pool
> 12 - Sewer
> 13 - J.C. Pool

## Swim survey areas:

Bird House (1) to Three Firs Pool (6) represents the upper survey section.
Marie Canyon (8) to enumeration fence (A) represents the middle survey section.
A - Refers to the adult enumeration fence

## Tag recovery locations:

Locations numbered 1 to 45 are in the upper river section, those numbered 46 to 83 are in the middle river section.

Figure 2. River management zones for the First Nations food fishery.

## A-Cliffs to Silver Bridge

B-Silver Bridge to J.C.'s Place
C-Quamichan to Black Creek
D-Powerline to Elliot's Barn
E-Elliot's Barn to Brian's Pool
F-Brian's Pool to Clem Clem and part of Koksilah

G-Clem Clem to Mouth of River
H-North Side to Fourplex
I-Fourplex to Meriner's Slough
J-Meriner's Slough to Mouth of River
