# Canadian Manuscript Report of Fisheries and Aquatic Sciences 2658 

## Canadian Manuscript Report of Fisheries and Aquatic Sciences

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-900 in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551.

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## Rapport manuscrit canadien des sciences halieutiques et aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques ques qui constituent une contribution aux connaissances actuelles, mais qui traitent de problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports manuscrits sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annual des publications scientifiques et techniques du Ministère.

Les numéros 1 à 900 de cette série ont été publiés à titre de manuscrits (série biologique) de l'Office de biologie du Canada, et après le changement de la désignation de cet organisme par décret du Parlement, en 1937, ont été classés comme manuscrits (série biologique) de l'Office des recherches sur les pêcheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de rapports manuscrits de l'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

Les rapports manuscrits sont produits a l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

#### Abstract

Nagtegaal, D.A., E.W. Carter, N.K. Hop Wo, and K.E. Jones. 2000. Juvenile chinook production in the Cowichan River, 2000. Can. Manuscr. Rep. Fish. Aquat. Sci. 2658: 37 p .

In 1991, Fisheries and Oceans Canada (DFO), Pacific Biological Station began a study of juvenile chinook salmon (Oncorhynchus tshawytscha) productivity in the Cowichan River. The 2000 study is concerned primarily with the enumeration and out-migration timing of naturallyreared chinook juveniles. The estimated production of naturally-reared chinook juveniles from the 1999 brood year was 673,726 (range: $546,060-915,723$ ). The release of juvenile chinook from the Cowichan River hatchery totaled $2,580,655$. Of these, $2,050,028$ hatchery-reared chinook were released above the trapping site. Egg to fry survival for naturally-reared chinook was estimated to be $6.54 \%$ (range: $5.30 \%-8.89 \%$ ). Trapping results maintain that most hatchery-reared chinook migrate to the Cowichan estuary within one week of release. Interaction between naturally-reared and hatchery-reared chinook juveniles is therefore believed to be limited.

## RÉSUMÉ

Nagtegaal, D.A., E.W. Carter, N.K. Hop Wo, and K.E. Jones. 2000. Juvenile chinook production in the Cowichan River, 2000. Can. Manuscr. Rep. Fish. Aquat. Sci. 2658: 37 p .

En 1991, la Station biologique du Pacifique de Pêches et Océans Canada a entrepris une étude sur la productivité du saumon quinnat (Oncorhynchus tshawytscha) juvénile de la rivière Cowichan. L'étude de 2000 a consisté principalement à dénombrer les saumons quinnats juvéniles d'origine naturelle et à déterminer le moment de leur dévalaison. La production de saumons quinnats juvéniles d'origine naturelle de l'année d'éclosion 1999 a été estimée à 673726 (étendue : $546060-915723$ ). Au total, 2580655 saumons quinnats juvéniles élevés dans l'écloserie de la rivière Cowichan ont été libérés, dont 2050028 en amont du site de piégeage. La survie des oeufs d'origine naturelle jusqu'au stade d'alevin a été estimée à $6,54 \%$ (étendue : $5,30 \%-8,89 \%$ ). Les résultats de piégeage indiquent que la plupart des saumons quinnats élevés en écloserie migrent vers l'estuaire de la Cowichan dans la semaine qui suit leur libération dans la rivière. Les interactions entre les saumons quinnats juvéniles d'origine naturelle et ceux provenant de l'écloserie sont donc considérées comme limitées.

## INTRODUCTION

Situated in southeastern Vancouver Island, the Cowichan watershed is one of the most important salmonid producing systems draining into the Strait of Georgia (Candy et al. 1995). Chinook (Oncorhynchus tshawytscha), coho (O. kisutch), chum (O. keta), steelhead (O. mykiss), cutthroat ( $O$. clarki), as well as brown trout (Salmo trutta) and dolly varden (Salmo malma) spend periods of their life cycle or reside in this system. Historically, the chinook in this system have played an important role in the recreational, aboriginal, and commercial fisheries (Neave, 1949). Since 1958, the discharge of the Cowichan River has been controlled by a weir located at the outlet of Lake Cowichan, approximately 50 km upstream from the mouth of the Cowichan River (Burns et al. 1988). There have been periods of perceived salmonid population decline that have led to numerous studies (Lister et al. 1971; Candy et al. 1995; Nagtegaal et al. 1994-98).

Recent years have shown a dramatic decrease in the abundance of chinook throughout BC waters. The late 1970's were characterized by peak harvest rates of approximately 750,000 pieces. In the 1980's these rates dropped to numbers less than $25 \%$ of their former abundance (Argue et al. 1983). For this reason, many stock rebuilding initiatives were implemented. In 1979, the Cowichan River Hatchery initiated a chinook enhancement program. Production began with a modest output of less than 70,000 chinook fry and grew to $2,580,655$ chinook fry in 2000 (Candy et al. 1996; D. Millerd, Cowichan River community economic development hatchery manager, P.O. Box 880, Duncan, B.C., pers. comm.).

As in previous years, a portion of hatchery produced chinook were coded-wire tagged (CWT). Fisheries managers rely heavily on information provided by tagged salmonids to evaluate the strategies for each hatchery program. The data from tag recoveries also provides key information regarding stock migration, harvest rates, and a measure of enhanced contribution to the stock (Nagtegaal et al. 1998). In 2000, the portion of hatchery produced chinook which were coded-wire tagged were 224,579 fry.

In 1985, a chinook rebuilding strategy in conjunction with the Pacific Salmon Treaty, led to the Cowichan River's inclusion into a naturally spawning chinook study. Along with the Nanaimo and Squamish River stocks, the Cowichan River was chosen as an escapement and exploitation indicator to monitor the status of Lower Strait of Georgia chinook stocks and the rebuilding of escapement into these systems (Nagtegaal et al. 1998). The accurate enumeration of chinook migrants is also an important resource management tool. For this reason the results of this ongoing study can be used to assess enhancement strategies and harvest management practices, as well as investigate possible interactions between hatchery-reared chinook and naturally-reared chinook. Since then, the Nanaimo and Squamish Stocks are no longer used as indicators.

For the purposes of this study, we refer to hatchery-reared fish as those that were spawned and reared in the hatchery environment regardless of parental origin, and naturally-reared fish as those that spawned and reared in the river environment. The naturally-reared juvenile chinook of Cowichan River are considered to be the "ocean-type". This means that they usually migrate to
sea within three months of emergence (Healey, 1991). Lister et al. (1971) subdivided the Cowichan chinook migrants into two distinct groups. The 'early group' comprises the majority of the migrants and consists mainly of newly emerged fry with an average length of approximately 42 mm . The 'early group' migrates to the estuary in March and April. The 'late group' as described by Lister are larger with lengths averaging over 55 mm . This group may rear in the river system for up to 90 days before migrating to the estuary in May and June. This 'late group' may account for approximately $15 \%$ of the total juvenile chinook population.

## METHODS

## STUDY SITE DESCRIPTION

The Cowichan River begins at the Lake Cowichan weir and drains the mountainous slopes of the Vancouver Island range with a watershed area of $840 \mathrm{~km}^{2}$ (Candy et al. 1995). Approximately 40 km north of Victoria, the Cowichan River flows eastward through the City of Duncan, and carries a mean annual discharge of $36.6 \mathrm{~m}^{3} / \mathrm{s}$. Skutz Falls, located 18 km downstream of Lake Cowichan, is a partial obstruction to the upstream migration of chinook spawners (Figure 1). In 1956, a fishway was built to help alleviate this problem (Lister et al. 1971). The Cowichan chinook spawn primarily in the mainstem, above Skutz Falls.

The rotary trap was placed at the City of Duncan old Pumphouse site (Figure 1). It was assumed that virtually all chinook spawning occurred above this point. The rotary screw trap was located at site 7A for the entire duration of the study in 2000 (Figure 1).

## FISH CAPTURE

A rotary screw trap, 2.4 m in diameter was used to trap juveniles migrating downstream to the Cowichan Estuary. Fish passing through the cone were collected in a live box. In operation from February 21 to May 16, the trap was held in place by a galvanized steel cable which secured the trap at site 7 (the lower Pumphouse site). The trap was set for fishing and then sampled on alternating days. The trap was set at approximately 1900 h and fished continuously until 0700 h the following morning at which time the trapped fish were removed and sampled. The trap was then set again on the following evening after sampling had occurred. During efficiency tests, trapping occurred continuously over 24 -hour periods and the trap was checked at both 0700 and 1900 h to monitor day and night fry migration.

All fish captured were enumerated by species and recorded by time period and capture date. Chinook migrants were identified as hatchery-reared or naturally-reared, based on identifiable physical characteristics (size, absence or presence of an adipose fin). Coho were recorded as either fry, one or two year old smolts. Biophysical conditions (water temperature, flow rates, water clarity, and weather conditions) were also noted.

## ABUNDANCE ESTIMATES

Trap efficiency information, using the mark-recapture of Bismarck Brown ${ }^{1}$ stained juvenile fish (Ward and Verhoeven 1963), was used to expand the trap catch to estimate total numbers migrating past the trap site. Juvenile chinook and chum were stained, and then released approximately 500 m upstream from the trap site. The number of stained fish recaptured from continuous trapping over the next two to three days was recorded.

The proportion of marked fish recaptured was used to expand unmarked fish catch and estimate the total number of fish. Mark-recapture estimates were conducted on a biweekly basis.

Trap efficiency was estimated using:

$$
E_{i j}=\frac{m_{i j}}{M_{i j}}
$$

where:
$E$ is the estimated trap efficiency at site $i$, on day $j$. $m$ is the number of marked fish recaptured at site $i$, on day $j$. $M$ is the number of marked fish released at site $i$, on day $j$.

Inherent in these efficiency tests were the following assumptions:
i. marking of the fish does not affect short term survival of these fish, ii. all marked fish released above the trap site migrate downstream past the trap, iii. marked fish behave the same as unmarked fish, and $i v$. all recaptured fish were counted.

24-hour fry enumeration was estimated by:

$$
F=\underline{H}
$$

where:
$F$ is the factor used to expand night estimates into 24 -hour fry migration estimates.
$H$ is the total number of fish caught during 24-hour trapping periods.
$h$ is the total number of fish caught during the night portions of corresponding 24hour trapping periods.

Diel migration periods were non-sequential sampling days conducted throughout the course of the fry enumeration study. Twenty-four hour estimates were expanded for portions of the day when the trap was not in operation.

[^0]The total number of fish per day was estimated by:

$$
N_{i j}=\frac{U_{i j}}{E_{i j}} * F
$$

where:
$N$ is the estimated number of fish that swam past site $i$, on day $j$. $U$ is the catch of unmarked fish in the trap, at site $i$, on day $j$.

The total abundance was then determined by summing the daily totals for the duration of trapping. For those nights when no trapping occurred (for example, Tuesday, Thursday, Saturday and Sunday) we assumed the number of migrants to be an average value obtained from the previous and post nights sampling. The total abundance estimate was taken from the sum of the daily catch estimates for the duration of the study (Nagtegaal et al. 1997).

## JUVENILE CHINOOK GROWTH

Observations on growth for naturally-reared chinook were obtained by collecting 30 samples from each catch of the rotary trap. For two days after a hatchery fry release 15 hatcheryreared chinook fry were sampled. Chinook migrants were measured to the nearest millimeter ( mm ) fork length, and weight was recorded to the nearest one hundredth of a gram (g).

## RESULTS

## BIOPHYSICAL CONDITIONS

During the fry enumeration period the Cowichan River had three main water discharge peaks, with the largest discharge of $70.0 \mathrm{~m}^{3} / \mathrm{s}$ on March 2 and two lesser peaks of $60.3 \mathrm{~m}^{3} / \mathrm{s}$ on March 23 and $57.4 \mathrm{~m}^{3} / \mathrm{s}$ on May 7. The lowest Cowichan River discharge level was of $35.9 \mathrm{~m}^{3} / \mathrm{s}$ was recorded on April 21. The mean discharge during the course of the study was $49.1 \mathrm{~m}^{3} / \mathrm{s}$ with the February portion averaging $48.8 \mathrm{~m}^{3} / \mathrm{s}$; March yielding a $55.3 \mathrm{~m}^{3} / \mathrm{s}$ average; April a $43.0 \mathrm{~m}^{3} / \mathrm{s}$ average; and the May portion a $48.9 \mathrm{~m}^{3} / \mathrm{s}$ average water discharge (Figure 2). Flow rates decreased from a high of $1.85 \mathrm{~m} / \mathrm{s}$ on March 24 to a low of $1.25 \mathrm{~m} / \mathrm{s}$ on April 21. Water temperatures averaged $7.3^{\circ} \mathrm{C}$ and increased from $3^{\circ} \mathrm{C}$ on February 21 to $12^{\circ} \mathrm{C}$ on May 15 . A graphical representation of river discharge and water temperature for the Cowichan River during the course of the study is presented in Figure 3.

On a regular basis, there was a build up of small organic debris in the trap. However, when this occurred there was no noticeable difference in the fishing efficiency of the rotary trap. Water clarity at the trapping site was recorded daily as either clear or cloudy. Sixteen sample periods ( $28.1 \%$ ) were recorded as cloudy water clarity with other days recorded as clear water clarity. During the time of the study there were only four sample periods when rain was recorded (Table 1).

## MIGRATION TIMING

The fry enumeration trap was run for 57, 12-hour intervals between February 21 and May 16, 2000. At the Pumphouse site, 12,133 naturally-reared and 76,011 hatchery chinook juveniles were caught in the screw trap. The number of hatchery-reared chinook fry enumerated also included 683 adipose-clipped fish. In addition, 200,441 chum fry, 7,372 coho fry, 3,265 one year old coho, 47 Bismarck Brown dyed chinook fry and nine Bismarck Brown dyed chum fry (Table 1). The downstream movement of hatchery chinook was observed from March 7 ( 21,172 fry) to May 16 ( 31 fry). It was understood that the hatchery fish released in the upper river would have reached the trapping site within approximately one week of their release date (Nagtegaal et al. 1998). Naturally-reared chinook migration had peaked on March 28 and hatchery-reared enumeration peaked on March 7 and April 28 (Figure 4; Figure 5).

## HATCHERY RELEASES

Cowichan River Hatchery had four chinook fry release strategies with two releases 30 km above the trapping site. The first release occurred in the upper Cowichan River at the Roadpool site on March 7 with $1,086,403$ fry being released of which 99,729 fry carried CWT's. The second release was also in the upper Cowichan River where 49,615 CWT fry of 963,625 total fry were released on April 27. Two Cowichan River Hatchery releases occurred below the fry enumeration site. A release on May 5 from the Hatchery site released 430,691 fry of which 50,157 fry had CWT's. The final chinook fry release of the year was from the Seapen site in Cowichan Bay on May 17 where 25,078 CWT fry of 99,936 total fry were released into the ocean. A summary of all releases from the Cowichan River Hatchery is presented in Table 2.

## DIEL MIGRATION

This year's study included a continuous 24-hour trapping component to determine diel migration. The 24 -hour fry enumeration periods were conducted on 11 days between March 2 and April 29. The diel migration tests were stratified into naturally-reared fry and hatcheryreared fry components. A combined total of 4,188 naturally-reared chinook fry were counted with 3,752 fry obtained during night hours ( $\sim 1900-0700$ hours) and 436 fry collected during day hours ( $\sim 0700-1900$ hours) (Table 3). An expansion factor of 1.116 for naturally-reared chinook fry was obtained from the combined totals of the 24 -hour trapping periods. Diel migration testing with hatchery-reared chinook yielded 27,182 fry of which 26,371 were caught during night hours and 811 were caught during daylight hours (Table 4). An expansion factor of 1.031 was obtained for hatchery-reared fry.

## TRAP EFFICIENCIES

Four efficiency tests were conducted on March 1, March 15, March 29 and April 19 during the 2000 fry enumeration study (Figure 5). The results were stratified into two categories with March 1 and March 15 results combined and subsequent March 29 and April 19 results combined. This division allows for potential efficiency differences due to river flow, river hydraulics and variation in fry behavior over the course of the study (Figure 6).

During the first set of efficiency tests a total of 833 Bismark Brown dyed chinook were released on March 1 and March 15. Fry recoveries were run for 48-60 hours after each release date and yielded a total of 27 Bismark Brown dyed chinook fry. An expansion factor of 30.85 was calculated from these results and used to expand February 22 to March 22 daily fry counts (Table 5).

The second set of efficiency tests on March 29 and April 19 released 473 Bismark Brown dyed chinook and 250 dyed chum fry of which 20 chinook and nine chum were recovered. Excluding the chum fry data, an expansion factor of 23.65 was calculated to expand the March 23 to May 16 fry enumeration data (Table 5).

## ABUNDANCE ESTIMATES

Abundance estimates were based on fry counts collected from the fry enumeration trap. When fry count data were not available, an estimate was calculated by using the average of adjacent fry trap enumeration days. If no day count was available, the night count was expanded by 1.116 for naturally-reared fry and 1.031 for hatchery-reared fry obtained from diel migration results. Daily estimates were then expanded by the trap efficiency estimates with February 22 to March 22 estimates expanded by 30.85 and March 23 to May 16 estimates expanded by 23.65 . Total Cowichan River naturally-reared chinook is estimated to be 637,726 fry (Table 6) while the hatchery-reared chinook estimated is $2,182,557$ fry (Table 7).

Population estimate ranges were calculated by using the lowest and highest diel and trap efficiency expansion factors. The lower population range for naturally-reared fry used a diel expansion factor of 1.000 obtained from April $29(\mathrm{n}=183)$ and a trap efficiency expansion factor of 23.28 obtained on March $29(\mathrm{n}=419)$. The upper population range for naturally-reared fry was calculated using a diel expansion factor of 1.343 from March $2(\mathrm{n}=682)$ and a trap efficiency expansion factor of 42.13 obtained on March $1(n=337)$. Population estimate ranges for naturally-reared chinook fry are 546,060 to 915,723 . Similarly, hatchery-reared fry ranges were calculating using the lower (1.000; April 29; $\mathrm{n}=9,750$ ) and upper ( 1.060 ; March $9 ; \mathrm{n}=$ $13,357)$ results of the hatchery-reared diel migration tests. Using the same upper and lower trap efficiency factors as naturally-reared fry yielded hatchery-reared chinook fry ranges of $1,800,193$ to $2,721,067$.

A coho mark-recapture study in Cowichan Lake provides supplementary data about chinook fry in the upper Cowichan River. A fyke trap was in place just downstream of

Cowichan Lake from April 19 to May 19, 2000. During this time, 65 chinook fry were enumerated. From May 20 to June 28 a rotary screw trap replaced the fyke trap and 3,193 chinook fry were counted. A total of 3,258 chinook fry were enumerated during the coho markrecapture study in the upper Cowichan River between April 19 and June 28. Results from the Cowichan Lake coho mark-recapture study are presented in Table 8.

## EGG TO FRY SURVIVAL

To estimate the egg to fry survival rate, an accurate assessment of adult spawners, the percentage of females in the escapement, the average fecundity, and juvenile outmigration are needed. In 1999, the number of chinook natural spawners was estimated to be 4,500 fish and the proportion of females obtained from a carcass mark-recapture was determined to be $61.7 \%$, or 2,777 of total natural spawning chinook. The average fecundity from broodstock biosample data were determined to be 3,711 eggs and the total egg production was estimated to be $10,303,947$ (Figure 7). The estimated abundance of naturally-reared chinook fry was extrapolated to 673,726 and the egg to fry survival was therefore estimated to be $6.54 \%$. The egg to fry survival range was calculated using the lower and upper ranges of estimated fry production and the estimated number of eggs produced. Lower and upper egg to fry survival ranges were $5.30 \%$ and $8.89 \%$, respectively. The number of naturally-reared chinook eggs deposited and subsequent fry production are compared in Figure 8.

## JUVENILE CHINOOK GROWTH

During the study period, 1,082 naturally-reared chinook fry were biosampled for length and weight. Mean length was approximately 40 mm and mean weight varied from $0.45-0.52 \mathrm{~g}$ until the beginning of April (Table 9; Table 10; Figure 9; Figure 10). From April 6 to May 13 naturally-reared fry increased in mean length from 40.6 to 54.2 mm and mean weight increased from 0.499 g to 1.584 g (Table 9; Table 10; Figure 9; Figure 10).

Hatchery-reared chinook were sampled four times totaling 60 fry during the course of the study and were generally longer and heavier set than naturally-reared chinook fry with length and weight ranges reflecting these differences (Table 9; Table 10). Size differences should have made most hatchery-reared fry easily distinguishable from naturally-reared chinook in the river. However, as the size of naturally-reared chinook increased during the study the potential for misidentification at the trap site also increased (Figure 9; Figure 10).

During four hatchery-reared sampling periods, no overlapping of length and weight ranges occurred with hatchery-reared fry sampled at corresponding time periods (Figure 9; Figure 10). Length and weight averages of hatchery-reared and naturally-reared chinook fry were compared and analyzed by a Student's t-test ( $\mathrm{p}<0.05$ ). Both the mean lengths and mean weights obtained from hatchery-reared fry were found to be statistically different than those obtained from naturally-reared fry.

## DISCUSSION

## BIOPHYSICAL CONDITIONS

Water turbidity or clarity would likely increase trap efficiency with decreased turbidity possibly resulting in more chinook fry being able to avoid the enumeration trap. The month of March had poor clarity which may have resulted in relatively higher trap efficiency. Conversely low river flows may increase trap efficiency decreasing the time fry have in avoiding an oncoming trap in the river. Flow rates during recapture periods ranged from a high of $1.85 \mathrm{~m} / \mathrm{s}$ on March 7 to a low of $1.25 \mathrm{~m} / \mathrm{s}$ on April 21. Low flow rates and other discharge dynamics, in combination with the cone rotation, may affect trap efficiency (Frith et al. 1995). Wetherall (1970) submitted that higher survival rates of migrants were observed with larger fish and high flows (discharges), while fingerlings in stream discharges less than $20 \mathrm{~m}^{3} / \mathrm{s}$ had lower survival rates.

## MIGRATION TIMING

In his report on the Cowichan River, Neave (1949) discusses a spring run of chinook that spawned primarily around the Cowichan Lake tributaries. He postulated that these spring run fish were near extinct in his time. Whether current populations of Cowichan Lake tributary chinook are remnants of a spring run or directly related to the lake pen release strategy is unknown.

Although considerable research has focussed on understanding the physiological and genetic aspects of chinook emigration, much less information exists on the factors affecting the timing of these migrations. According to Seelbach (1985) and Roper and Scarnecchi (1996), key factors that affect hatchery fish migration timing are size and time of outplanting and water velocities. Roper and Scarnecchi (1998) compared magnitude and emigration timing of chinook juveniles in the South Umpqua River with adult escapement and four environmental factors. They determined that the magnitude of adult escapement was closely related to the magnitude of juvenile production, lunar cycle, photoperiod and stream temperature were key factors affecting the timing of emigration.

## HATCHERY RELEASES

Hatchery release data are provided by the Cowichan River Hatchery and fry are released into the river approximately 30 km upstream of the fry enumeration site. Hatchery fry mortality for this 30 km stretch of river is unknown and it is assume not all fry swim past the enumeration trap. Therefore, the estimates provide from the Cowichan River Hatchery are assumed to be the most reliable source of hatchery-reared fry data.

Some level of interaction between the early naturally-reared chinook and hatchery-reared chinook in Cowichan River seems likely (Lister et al. 1971). A large proportion of naturallyreared chinook head to the estuary upon emergence and the migration of these chinook primarily
occurred between Feb 27 and April 10 (Figure 4). During this time the first hatchery release occurred on March 7 and some interaction between hatchery and naturally-reared chinook migrants was highly probable (Figure 4; Figure 5).

The late Roadpool hatchery release occurred on April 27. By this time the majority of 'early' chinook migrants had already passed the trapping site, and capture rates of these naturallyreared chinook had decreased substantially (Figure 4; Figure 5). Possible interactions between hatchery released chinook and the 'late' larger migrants could occur even if the hatchery fish move quickly to the estuary upon release, as Candy et al. (1996) indicated. The relatively large numbers of hatchery fish released and the assumed small population of 'late' migrants would suggest a very limited amount of interaction.

## DIEL MIGRATION

Diel migration tests were performed to provide an estimate of the proportion of fry that migrate into the fry trap in daylight hours ( $\sim 0700-1900$ hours) compared to nighttime hours ( $\sim 1900-0700$ hours). Diel migration testing was stratified into naturally-reared and hatcheryreared fry categories to account for potential biases arising from variations in behaviour between the two juvenile types.

## TRAP EFFICIENCIES

Due to the length of the Cowichan River study and constantly changing water flow rates stratifying the trap expansion results into two categories was necessary. The first two trap efficiency results were combined and represented the February 22 to March 22 portion of the study while the subsequent two efficiency results represented the March 23 to May 16 fry enumeration period.

Chinook abundance estimates using the Bismarck Brown mark-recapture method to calculate trap efficiency may be biased low. The assumption that stained fish have identical recapture rates as unmarked migrant chinook may be untrue as dyed fish have endured more handling and stress associated with the marking process. Therefore, swimming ability and behavior of these fish may be affected and translate into lower recapture rates (Nagtegaal et al. 1997). According to Frith et al. (1995), not all released marked fish are available for recapture as some fish are lost to predation, disease or residualization.

Efficiency tests from other studies (Thedinga et al. 1994, Roper and Scarnecchia 1996) indicate that there are considerable differences in trap efficiencies between species, flow rates and fish size. The trap efficiency release on April 19 consisted of primarily chum fry and that portion of the release was not utilized in calculating expansion factors. Possible differences in chum fry behavior and/or physiology between the two species could result in different trapping efficiencies than chinook fry provide.

Trap efficiencies may be affected by the stream characteristics in which the trap is placed. Site 7A is located in a riffle or run section of the Pumphouse site. Roper and Scarnecchi (1996) stated that hatchery-reared fish were often able to avoid a trap in a low velocity riffle area; however, when the trap was positioned at the head of a pool they were often caught. Since site 7A was exclusively used for this study, the difference in trap avoidance from a low velocity riffle area and the head of a pool was not applicable to this study.

For this study it was assumed that trap efficiencies for naturally-reared and hatcheryreared chinook were different due to size and behavioral differences. However, because only naturally-reared trap efficiency results were obtained, these results were used to expanded hatchery-reared fry caught in the rotary screw trap. Therefore the hatchery-reared fry estimate obtained from the fry enumeration trap is thought to be imprecise.

## ABUNDANCE ESTIMATES

Approximately 673,726 naturally-reared chinook fry migrated past the Cowichan River enumeration trap in 2000 (range: 546,060-915,723). This estimate did not take into consideration the migration of chinook prior to the installation of the rotary trap or after the study ended. It has been reported (Lister et al. 1971) that there is a later migration of juveniles that peaks in June.

Naturally-reared chinook fry population ranges were calculated rather than confidence intervals because they incorporate the two most influential fry enumeration variables, the diel migration expansion factor and the trap efficiency expansion factor. The ranges calculated in this report reflect how the diel migration and trap efficiency portions of this study can greatly influence fry population estimates. Therefore the accuracy of population estimates in this study rely primarily in the accuracy of diel and trap efficiency results.

Cowichan River Hatchery documented 2,050,028 hatchery fry being released above the fry enumeration trap site. This estimate is slightly lower than the value obtained from the fry enumeration trap and this result is unfeasible because the rotary screw trap estimate does not account for fry lost to predation or natural mortality during a 30 km migration downstream towards the fry trapping site. However, the hatchery release estimate is well within the $1,800,193$ $-2,721,067$ range provided by the enumeration trap. The higher estimate provided by the enumeration trap may be due to using efficiency results obtained from naturally-reared fry to expand hatchery-reared fry counts. Therefore the hatchery-reared fry estimate provided by the Cowichan River Hatchery is deemed more reliable than the rotary screw trap estimate.

Combined results from the fyke trap and rotary screw trap used in the coho markrecapture study suggest that some hatchery fry may not immediately migrate downstream upon being released. Some of these fry may be from the late hatchery release on April 27 (Table 2). It is possible hatchery fry may swim upstream into the Cowichan Lake before migrating downstream towards the estuary. Fry enumerated in the upper portion of the Cowichan River during June may also be part of the late migration of juveniles reported by Lister et al. (1971).

The 3,258 fry enumerated in the coho mark-recapture study indicate that results obtained from the Pumphouse rotary screw trap may underestimate the true chinook fry population migrating from the Cowichan River.

## EGG TO FRY SURVIVAL

The egg to fry survival estimate of $6.54 \%$ is higher than the $2.2 \%$ reported in the previous survey in 1999 (Nagtegaal and Carter 2000) but is above the 1990 - 1999 brood year average of $5.96 \%$. The 2000, egg to fry estimate is also below the ranges reported by Healey (1991) who had chinook fry survival ranges from $8 \%$ to $16 \%$ (Figure 7). The differences in survival rates among years may be attributed to many factors ranging from biophysical conditions, chum escapements and spawner distribution (Nagtegaal et al. 1997). However, the low egg to fry survival rate in 2000 (Figure 7), could be attributed to above average flow in both November and December of 1999. These high flows may have resulted in scouring of spawning beds and therefore loss of developing chinook fry. Montgomery et al. (1995) determined that the depth of stream bed scouring due to discharge levels was directly related to egg survival.

When comparing naturally-reared chinook eggs deposited and subsequent fry production there appears to be no reduction in fry abundance as egg production peaked in 1995 (Figure 8). This suggests the maximum number of chinook eggs the Cowichan River supports has not yet been reached.

## JUVENILE CHINOOK GROWTH

Fry length and weight sampling during the study showed little increase in average size of naturally-reared chinook until after April 6. Misidentification between the two fry types is most likely minimal, as sampling results show no overlapping size ranges during sampling periods (Figure 9; Figure 10). However, as the study progressed the difference between size ranges appeared to be decreasing making it harder to differentiate between the two fry types (Figure 9; Figure 10). According to one participant at the trapping site, the identification of naturally-reared versus hatchery-reared chinook became more difficult after the late hatchery release.

Variation in rearing environments between hatchery-reared and naturally-reared fry is likely the underlying factor in morphological differences such as mean weight and mean length. Hatchery-reared fry spend the winter months at the hatchery in various holding tanks and are fed fish pellets until being released during the spring months. Alternatively, naturally-reared fry are dependent on foraging for food within an environment with only limited resources. This difference in rearing environments results in naturally-reared fry growing at a slower rate than hatchery-reared fry.

## ACKNOWLEDGEMENTS

We would like to thank Dave Key and James Patterson for assisting with the installation and removal of the trap. We thank Art Watson and the Lake Cowichan Salmonid Enhancement Society for providing the funding for the labour to operate the rotary trap, collect the trapping and biosampling data, and for providing the chinook sampling information from the coho trapping project. Without this funding the project could not have been completed. We thank Dave Burton and Gary Gladman for collecting and sampling the trap catch on a daily basis. We would like to thank D. Millerd and the staff of the Cowichan River Hatchery for the provision of chinook fecundity, tag and release information. The City of Duncan has our gratitude for again allowing us to use their Pumphouse facility. We thank Water Survey Canada for providing the Cowichan River discharge information.
