Canadian Technical Report of Fisheries and Aquatic Sciences

These reports contain scientific and technical information that represents an important contribution to existing knowledge but which for some reason may not be appropriate for primary scientific (i.e. *Journal*) publication. Technical Reports are directed primarily towards a worldwide audience and have an international distribution. No restriction is placed on subject matter and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries management, technology and development, ocean sciences, and aquatic environments relevant to Canada.

Technical Reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report will be abstracted in *Aquatic Sciences and Fisheries Abstracts* and will be indexed annually in the Department's index to scientific and technical publications.

Numbers 1-456 in this series were issued as Technical Reports of the Fisheries Research Board of Canada. Numbers 457-714 were issued as Department of the Environment, Fisheries and Marine Service, Research and Development Directorate Technical Reports. Numbers 715-924 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Technical Reports. The current series name was changed with report number 925.

Details on the availability of Technical Reports in hard copy may be obtained from the issuing establishment indicated on the front cover.

Rapport technique canadien des sciences halieutiques et aquatiques

Ces rapports contiennent des renseignements scientifiques et techniques qui constituent une contribution importante aux connaissances actuelles mais qui, pour une raison ou pour une autre, ne semblent pas appropriés pour la publication dans un journal scientifique. Il n'y a aucune restriction quant au sujet, de fait, la série reflète la vaste gamme des intérêts et des politiques du Ministère des Pêches et des Océans, notamment gestion des pêches, techniques et développement, sciences océaniques et environnements aquatiques, au Canada.

Les Rapports techniques peuvent être considérés comme des publications complètes. Le titre exact paraîtra au haut du résumé de chaque rapport, qui sera publié dans la revue *Aquatic Sciences and Fisheries Abstracts* et qui figurera dans l'index annuel des publications scientifiques et techniques du Ministère.

Les numéros 1-456 de cette série ont été publiés à titre de Rapports techniques de l'Office des recherches sur les pêcheries du Canada. Les numéros 457-714, à titre de Rapports techniques de la Direction générale de la recherche et du développement, Service des pêches et de la mer, ministère de l'Environnement. Les numéros 715-924 ont été publiés à titre de Rapports techniques du Service des pêches et de la mer, Ministère des Pêches et de l'Environnement. Le nom de la série a été modifié à partir du numéro 925.

La page couverture porte le nom de l'établissement auteur où l'on peut se procurer les rapports sous couverture cartonnée.

Chandler, R. A., G. J. Parsons, and M. J. Dadswell. 1989. Upper and northern Bay of Fundy scallop surveys, 1986-87. Can. Tech. Rep. Fish. Aquat. Sci. 1665: iii + 37 p.

ABSTRACT

Chandler, R. A., G. J. Parsons, and M. J. Dadswell. 1988. Upper and northern Bay of Fundy scallop surveys, 1986-87. Can. Tech. Rep. Fish. Aquat. Sci. 1665: iii + 37 p.

A survey was conducted to gather baseline data on populations, associated fauna, and biological parameters for sea scallop (Placopecten magellanicus) in the upper and northern Bay of Fundy. This primary survey was in response to recent vigorous commercial activity in an area that, historically, had contributed very little to total landings for the Bay of Fundy. Our catches were generally low but eight locations (25% of the stations) where scallops were concentrated (>5 kg round weight/tow) were identified. Meat yields of the Bay of Fundy decreased towards the head of the Bay, yet early growth was very rapid. A high scallop prerecruit (<75 mm shell height) abundance indicated good potential recruitment in some areas.

RÉSUMÉ

Chandler, R. A., G. J. Parsons, and M. J. Dadswell. 1988. Upper and northern Bay of Fundy scallop surveys, 1986-87. Can. Tech. Rep. Fish. Aquat. Sci. 1665: iii + 37 p.

Un relevé a été effectué pour recueillir des données de base sur les populations de pétoncles génants (Plecopecten magellanicus), la faune connexe et les paramètres biologiques dans le fond de la baie de Fundy et dans sa partie nord. Ce premier relevé a été exécuté comme suite à une pêche commerciale qui récemment s'était avérée assez active dans un secteur qui historiquement avait très peu contribué au total des débarquements pour la baie de Fundy. Règle générale, nos prises ont été faibles, mais nous avons cerné huit secteurs (25 % des postes) où se concentraient les pétoncles (> 5 kg poids brut par trait de chalut). Le rendement pour ce qui est de la chair de pétoncles dans la baie de Fundy était moins important dans le secteur du fond de la baie quoique la croissance ait été fort rapide dans les premières étapes du développement. Un taux d'abondance élevé du pétoncle avant le recrutement (taille du pétoncle de < 75 mm) laissait pressentir un bon taux de recrutement dans certains secteurs.

INTRODUCTION

Sea scallop (*Placopecten magellanicus* (Gmelin, 1791)) population assessments are routinely made in the Digby and Grand Manan areas of the Bay of Fundy (Jamieson et al. 1981; Dadswell et al. 1984; Robert et al. 1987), but no comprehensive scallop survey has been made in the upper (area A, Fig. 1) or northern (area B, Fig. 1) part of the Bay. In 1984-85, the area around Quaco Ledge and Ile Haute was heavily fished and, partly in response to this commercial activity, a survey was undertaken to determine scallop distribution.

High abundance of young scallops was reported by fishermen (W. Miner, pers. comm.) and researchers (Robert et al. 1987; pers. obs.) in most areas of the Bay of Fundy in 1985 and 1986, and we were particularly interested in their distribution and abundance in the upper Bay. As well, a substantial tagging program, primarily to study scallop movement and growth, was being conducted at that time and this cruise gave us an opportunity to increase our tag coverage.

During surveys in the Digby and Lurcher areas in the late 1960's, associated fauna caught in scallop drags were reported by Caddy (1970). We made similar observations and present some of the results here.

THE COMMERCIAL FISHERY

In the past, scallops had frequently been fished from deep water off Cape Spencer, N. B., but landings were low, especially in the upper Bay where they averaged <1 t of meats annually. During 1980, landings began to increase and, by 1984, the upper Bay was being heavily fished. At that time there were 14 vessels, all under 14 m and registered with "Cumberland" or 3-mi licences, fishing out of upper Bay ports (Robert et al. 1987). However, up to 70 boats, some from as far away as Grand Manan, fished the upper Bay at its peak in 1985 (D. Graham, pers. comm.) when catches at local ports reached 55.9 t of meats valued at \$750,000 (Fig. 2, Table 1).

Five statistical districts are representative of the upper Bay of Fundy scallop landings: districts 48 and 79 in New Brunswick, where St.

Martins was home port for a large scallop fleet for several seasons, and districts 24, 40 and 44 in Nova Scotia (Fig. 1). Recent landings in these districts represent only a portion of the total catch from the upper Bay since a large number of Digby boats took part in the fishery and catches were landed at their home port (statistical district 38). Digby fishing logs (vessels >14 m) indicated that catch rates for the upper Bay varied from 4.48 to 17.00 kg per hour-meter (kg/hm) in 1985, depending on area fished (1.5-9.0 naut mi off Ile Haute), 3.00 kg/hm off Quaco Ledge in 1986 and 7.06 kg/hm for Ile Haute in 1987 (Robert, pers. comm.). The lack of fishing logs from upper Bay boats makes it difficult to determine their fishing performance; however, Robert et al. (1987) estimated that in 1985 and 1986, catch per vessel averaged 1630 kg and 1450 kg, respectively. By the time of our survey in May 1986, much of the earlier commercial activity had subsided and local landings dropped by 58% to 24 t of meats. During 1987, the catch rebounded to 48 t of meats.

METHODS

SURVEY

The survey consisted of three cruises using the Department of Fisheries and Oceans' vessel J.L. Hart. The upper Bay (area A) was surveyed in May 1986 (127 stations) and August 1986 (39 stations) and the northern side of the Bay (area B) from Quaco Head to Maces Bay in June 1987 (113 stations) (Fig. 3). The upper Bay was arbitrarily defined to the west by a line drawn from Port Lorne, N. S. to Quaco Head, N. B. A sampling grid with stations approximately 2 naut mi apart was established by using the Loran C main cross bearings on Canadian Hydrographic chart L/C4010 for area A and chart L/C4011 for area B. Commercial fishing areas in the upper Bay were identified from interviews with fishermen and fisheries officers and 27 extra tows were made in these areas by locating stations half way between the main "5930-x" Loran C cross bearing.

A tow of 8-min duration was conducted at each station using a four-gang Digby drag (Appendices 1a, 1b). Drag buckets were 76 cm wide and made of 75-mm rings knitted together with two rubber washers. The two inside drags were lined with 38-mm stretched mesh polypropylene netting. While towing, Loran C bearings were recorded every 30 s to determine distance and location. Mean tow length for all stations was 721 ± 27 m. Average calculated speed was 3 knots.

The total scallop catch from each bucket was weighed whole and shell height frequencies (in 5-mm shell height increments) recorded for live and dead (cluckers) individuals. Catches were averaged separately for the two lined and two unlined buckets and were each adjusted to a four-gang drag. This catch was then prorated to a tow length of 800 m (Robert et al. 1984) (Appendices 2a-d). Scallops <75 mm (shell height) are considered prerecruits, which approximates the shell height of the recently introduced regulation that prohibits harvesting scallops <3 in. (76.2 mm shell height) (Anon. 1987). Unlined drags caught 78% more recruits than lined drags. However, lined drags caught 41% more prerecruits than unlined ones. Therefore, the number of prerecruits was determined from catches in lined buckets and recruits were determined from unlined buckets (Robert et al. 1984). Similar gear behavior has been observed in several Bay of Fundy surveys (Jamieson and Lundy 1979; Robert et al. 1984; Parsons et al. 1987).

Samples of 30 scallops each (46-129 mm shell height range) were collected from six locations in the upper Bay and three in Minas Channel in May 1986, and from four locations off Cape Spencer in June 1987. Scallops were dissected on board, separated into meat (adductor muscle), gonad and remaining viscera, and then frozen. In the lab, the thawed tissues were weighed wet and reweighed after drying for 2 d at 85°C. Meat yields for a 90-mm shell height scallop were determined from shell height-wet meat weight regressions. Von Bertalanffy growth parameters were calculated (Allen 1967) for the upper and northern parts of the Bay using back-calculated growth rings. The

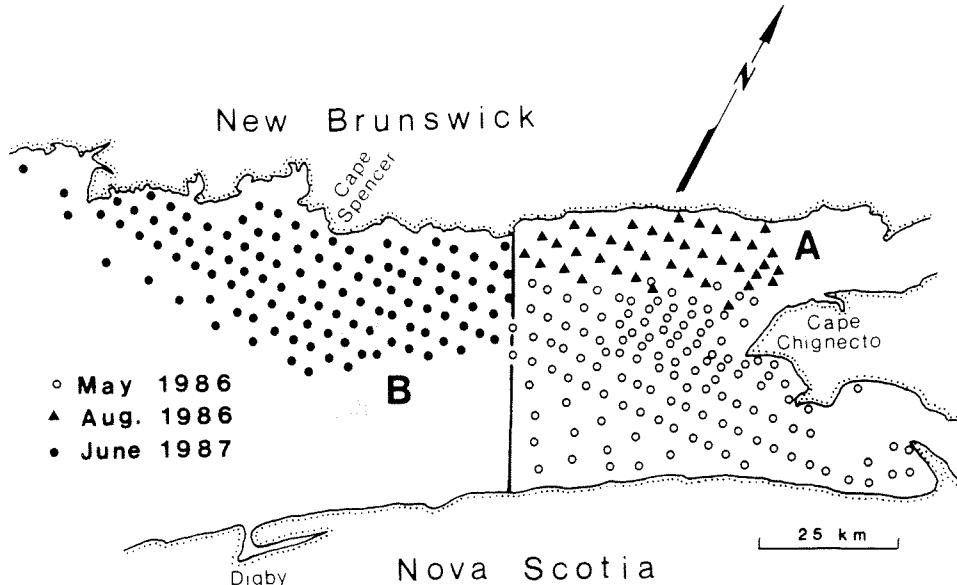

Fig. 3. Positions of tows made in area A in May (open circles) and August 1986 (closed triangles), and in area B in June 1987 (closed circles).

first annulus (approximately 25 mm shell height) represents shell growth attained by the second winter (i.e. 1.5 calendar years, approximately).

Bottom type and associated fauna were recorded for each tow. The associated fauna was quantified as follows: rare = 1-10 individuals, common = 11-100 individuals, and abundant = >100 individuals.

RESULTS AND DISCUSSION

Our catches generally reflected the low abundance of scallops reported by commercial fishermen in the upper Bay during 1986 and was demonstrated by the prorated weight of live scallops caught per tow in unlined drags (Fig. 4a). There were eight locations where scallops were concentrated and we have identified them by outlining areas or "beds" where tows exceeded prorated catches of 5 kg (Fig. 4b). Shell height frequencies for lined and unlined drags (Appendices 3a-h) and numbers of recruits and prerecruits per tow were calculated for these areas (Table 2).

CAPE CHIGNECTO BED

We made 15 tows on this bed (Appendix 1a; tows 4, 5, 7, 14, 15, 16, 17, 29, 33, 96, 138, 140, 141, 142, 147) which is located 4-5 naut mi northwest of Cape Chignecto and where a small fleet of local boats were fishing. The best catches in the upper Bay were from this bed and averaged 13.1 kg/tow (Appendix 2a).

Shell height frequencies for both lined and unlined gear show two modes of nearly the same magnitude at 50-55 mm and 115-120 mm, and a smaller one at 30-35 mm (Fig. 5, Appendix 3a). A fairly even catch of prerecruits (40/tow) and recruits (48/tow) (Table 2) indicated that this area had good commercial potential. Percent dead (number of cluckers/total number of scallops

Table 2. Average prorated number of scallop prerecruits (<75 mm shell height) and recruits caught per tow by area. Recruit abundance was calculated using catches from the unlined gear and prerecruits from the lined gear.

Area	Prerecruits	Recruits
Cape Chignecto bed	40	48
Advocate Bay bed	82	52
Scots Bay bed	1	52
Ile Haute bed	3	58
East Quaco bed	35	55
West Quaco bed	18	55
Cape Spencer inshore bed	150	125
Cape Spencer offshore bed	274	90
Upper Bay of Fundy	9	11
Northern Bay of Fundy	87	37

caught) for prerecruits and recruits were nearly the same, 10.4% and 10.8%, respectively.

Bottom type was predominantly sand with a mixture of mud and shell gravel. Small boulders were common and the bryozoan *Flustra foliacea* was abundant (Fig. 8a). Depth averaged 36 m.

ADVOCATE BAY BED

Five tows were made in Advocate Bay but only one area (Appendix 1a; tow 30) had sufficient catch (20.6 kg) for commercial exploitation. High abundance of small scallops in several areas in the Bay were reported by fishermen (L. Fletcher, pers. comm.) and divers (K. Stokesbury). This was confirmed by our survey. We found a strong mode at 50-60 mm (Fig. 5, Appendix 3b). Number of cluckers was low, 2.6% for prerecruits and 7.7% for recruits. Catches suggested good commercial potential in this area.

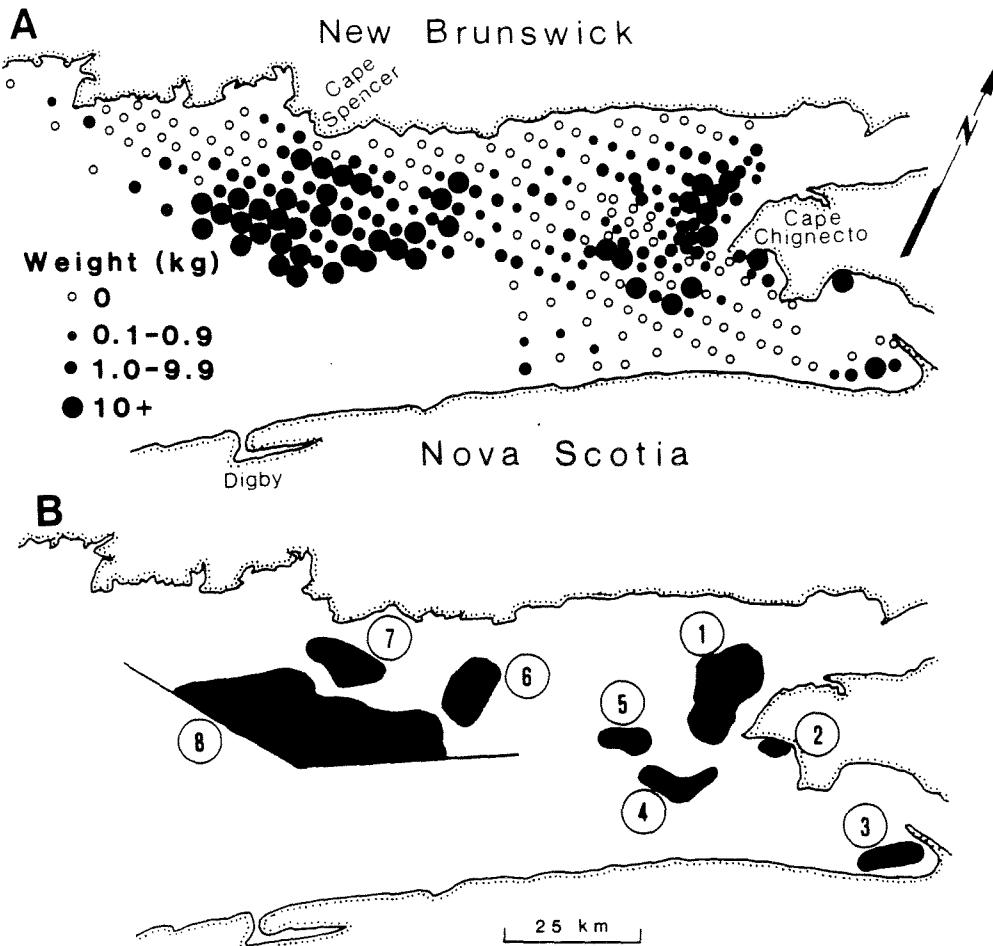

Fig. 4a. Scallop distributions prorated to reflect weight of whole scallops/ 800-m tow for 4 gang unlined drag.

4b. Location of scallop concentrations where prorated catches exceeded 5 kg: 1. Cape Chignecto bed, 2. Advocate Bay bed, 3. Scots Bay bed, 4. Ile Haute bed, 5. East Quaco bed, 6 West Quaco bed, 7. Cape Spencer inshore bed, 8. Cape Spencer offshore bed.

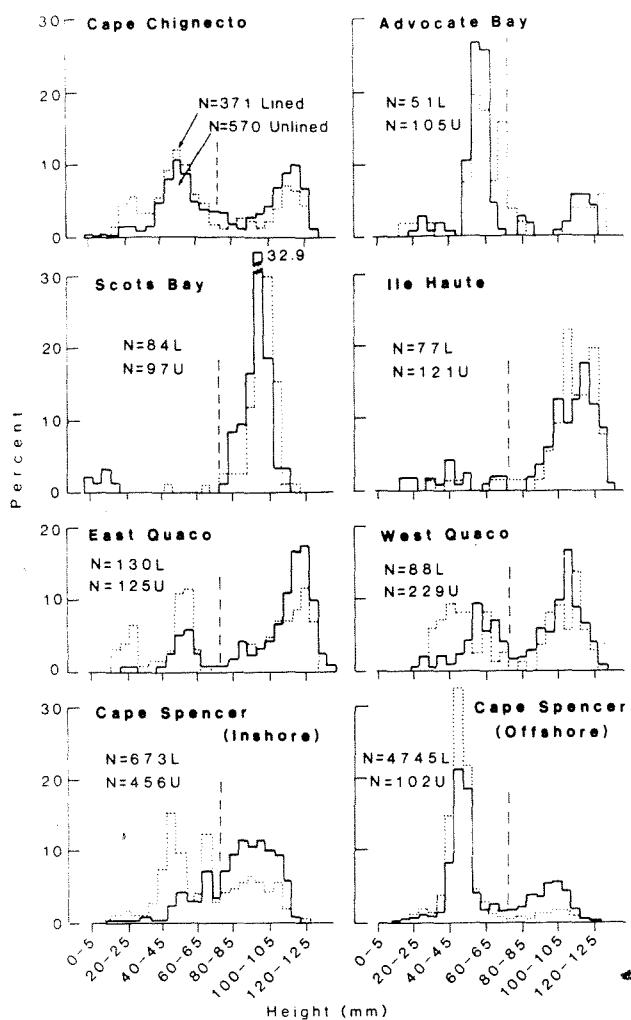

Fig. 5. Shell height frequency of scallops captured in lined and unlined drags. The dashed line is at 75 mm which approximates the minimum legal shell height of scallops available to the fishery.

Bottom type was mostly sand mixed with shell and gravel and small boulders. Flustra foliacea was abundant (Fig. 8a). Depth was 31 m.

SCOTS BAY BED

Three tows identified this bed (Appendix 1a; tows 85, 88, 90). Scallops were fairly abundant with catches averaging 9.6 kg/tow (Appendix 2a), but these scallops were poorly developed (i.e. their growth rate and meat yield were low) perhaps due to heavy shell infestation of the boring sponge, Cliona sp. There was a strong mode at 95-105 mm (Fig. 5, Appendix 3c). Prerecruits numbered one per tow, the lowest in our survey (Table 2). Percent cluckers was high for both prerecruits (33.3%) and recruits (25%).

Bottom was predominantly mud in shallow water (18 m) and gravel and small boulders in deeper water (33 m).

ILE HAUTE BED

Four tows were made in this bed (Appendix 1a; tows 44, 50, 51, 52). Catches averaged 12.8

kg/tow (Appendix 2a). Only one broad mode encompassing size increments from 100-140 mm was found (Fig. 5, Appendix 3d) with very few prerecruits (2.7/tow) (Table 2). Commercial potential appeared poor. The ratio of dead scallops (recruits) was 9.9%.

Depth was 45 m with bottom type being predominantly sand and small boulders. Flustra foliacea and Hyas coarctatus (toad crabs) were abundant.

EAST QUACO BED

Four tows were made in this bed (Appendix 1a; tows 39, 40, 102, 104). Mean catch was 11.4 kg/tow (Appendix 2a). Two modes were present, a small mode at 40-60 mm and a stronger one consisting of larger scallops with shell heights at 115-125 mm (Fig. 5, Appendix 3e). There was an average of 55 recruits/tow (Table 2) with 9.0% cluckers. Prerecruits averaged 25/tow and had a clucker ratio of 24.7%.

Depth was 54 m and bottom type was mainly sand and small boulders. Flustra foliacea and the horse mussel (Modiolus modiolus) were common (Fig. 8a, b).

WEST QUACO BED

Six tows were made in this bed (Appendix 1b; tows 42, 43, 47, 48, 93, 94). Average catch per tow was 12.0 kg (Appendix 2c). Two modes were present, a strong recruit mode at 105-110 mm and a broad, smaller mode at 40-60 mm (Fig. 5, Appendix 3f). Recruits averaged 55/tow (Table 2), with a low ratio of cluckers (1.4%) and prerecruits averaged 18/tow, with a high number of dead scallops (25%).

Depth varied from 45 to 70 m and bottom type was mostly sand and shell with small boulders. A horse mussel (Modiolus modiolus) bed was on the inshore part of this bed (Fig. 8b). Flustra foliacea occurrence was patchy (Fig. 8a).

CAPE SPENCER INSHORE BED

Five tows were made in this bed (Appendix 1b; tows 21, 35, 36, 37, 38). Catches were much higher in this area than found anywhere else in area A, and averaged 17.8 kg/tow (Appendix 2c). There were two modes for prerecruits, one at 40-45 mm and another at 65-70 mm. There was a broad recruit mode between 80-110 mm (Fig. 5, Appendix 3g). Prerecruits averaged 150/tow (Table 2) but had a high clucker ratio of 53.7%. Recruits averaged 125/tow, the highest of our survey, with a low number of dead scallops (0.9%). This bed should have good commercial potential if prerecruits survive.

Bottom was between 45-70 m with a mixture of sand, gravel and rock. Flustra foliacea was less abundant here than on other beds to the east (Fig. 8a).

CAPE SPENCER OFFSHORE BED

Thirty-six tows were made in this bed (Appendix 1b; tows 11, 18, 21, 25, 26, 27, 28, 29, 30, 31, 33, 35, 36, 37, 38, 52, 53, 54, 55, 56, 57, 58, 59, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112). This was the

largest bed and most promising area in our survey. The outer boundary was not delineated as it went beyond our survey mandate. Average catch was 18.0 kg/tow. The best catch of the survey occurred 13 naut mi south of Cape Spencer where tow 107 yielded 51 kg. There was a strong prerecruit mode at 45-55 mm (Fig. 5, Appendix 3h) with a weaker recruit mode at 95-105 mm. Prerecruits averaged 274/tow and had a clucker ratio of 15.2%, which was much lower than found inshore. Recruits averaged 90/tow (Table 2).

Depth was 80-100 m, the bottom a mixture of sand-mud. A large horse mussel bed occurred in the eastern part of this bed (Fig. 8b).

GROWTH AND MEAT YIELDS

Growth in the upper Bay appeared to be quite rapid for the first 3-4 yr (2-yr-old = 54.3 mm, 3-yr-old = 74.7 mm, Fig. 6, Table 3a, Appendix 4a), compared to that found at Grand Manan

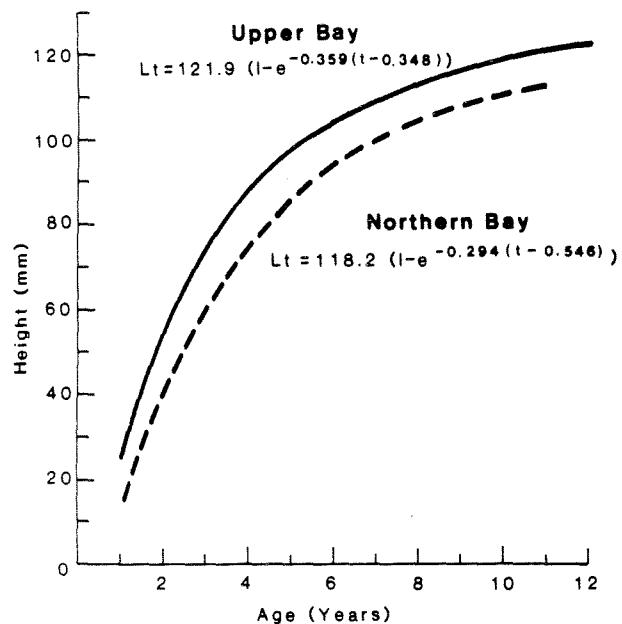

Fig. 6. Von Bertalanffy growth curves of scallops captured in the upper and northern areas of the Bay of Fundy.

(equivalent to 47.8 mm and 68.0 mm (Robert and Lundy 1987)) and Digby (equivalent to 43.3 mm and 63.2 mm (Robert et al. 1987)). However, maximum growth attained in the upper Bay was lower ($L_{\infty} = 121.9$ mm for upper Bay, $L_{\infty} = 134.5$ for Grand Manan and $L_{\infty} = 143.2$ for Digby). Scallops off Cape Spencer appeared to be very slow growing (Fig. 6, Table 3b, Appendix 4b). More growth data should be obtained from this area to confirm these observations.

Scallop meat yields varied from area to area. In general, meat yields in the Bay of Fundy decrease towards the head of the Bay (Fig. 7). The lowest meat yields found in this survey occurred at Scots Bay (5.0 and 6.4 g for a 90-mm scallop). A sample from Quaco Ledge had a yield of 8.5 g/90-mm scallop, the highest in this survey (Table 4). However, Robert et al. (1984) found inshore Grand Manan to have a relatively high meat

Table 3a. Age and average shell height summaries of scallops from the upper Bay of Fundy. Observed values are from back-calculated growth rings and predicted values are from von Bertalanffy growth equation.

yield (10.1 g/90-mm scallop), and the highest yields in the Bay of Fundy occur in Passamaquoddy Bay (10.4/90-mm scallop) (Jamieson and Lundy 1979) (Fig. 7, Table 5).

ASSOCIATED FAUNA

The bryozoan, *Flustra foliacea*, was abundant in 46% of all tows and was very predominant above Cape Spencer (Fig. 8a). Caddy (1970) found it in the lower Bay of Fundy. This species can easily clog the rings of the drag and fill the buckets during even a short tow, resulting in poor gear efficiency and selectivity for scallops.

There is some interest in horse mussels, *Modiolus modiolus*, as a potential commercial species, but their growth appears to be slow, only reaching a length of approximately 76 mm (Caddy 1970, pers. obs.). They have a patchy distribution throughout the Bay and were abundant in only 17% of the tows (Fig. 8b).

Table 4. Location and regression constants for shell height-wet meat weight analysis for the upper Bay of Fundy, May 1986, and offshore of Cape Spencer, N.B., June 1987. Meat weights are calculated for a 90-mm scallop.

SCALLOP TAGGING

In the upper bay, 1674 young scallops were tagged at four sites (Greville Bay, 720; Advocate Bay, 299; Cape Chignecto, 454; and East Quaco, 201). Of special interest are 424 (mostly 2-yr-olds) released in May 1986 at a site in Greville Bay. By July 1987, 15% (62 tagged shells) were recaptured. When the 2-yr-olds (age at tagging) are considered by themselves, the release size was 51.1 mm (± 0.75 mm S.E.M.) and the recapture size was 87.8 mm (± 1.15 mm S.E.M.), a substantial growth increment of 71.8% over 14 mo, which confirms our observations on early rapid growth in the upper Bay. No other age groups of tag return scallops were analyzed for growth because of low sample sizes to date.

CONCLUSIONS

It would appear from our survey that there were some areas showing good recruitment and fisheries potential. Commercial interest will likely be sustained because of the high landed value of scallops, the limited possible expansion of alternate fisheries and the overcapacity of the Bay of Fundy fleet. Since biological data are scarce from the upper and northern Bay, future surveys may be warranted.

ACKNOWLEDGMENTS

G. Fawkes was especially helpful in that much of the computer work was done by him, from preparing the programs to running the summary data. W. McMullon and F. Cunningham drew the figures and B. Best and J. Hurley typed the report. P. McCurdy, J. Turner and C. Warren-Perry assisted with sea sampling. Thanks to the captain and crew of the J. L. Hart, especially Capt. F. S. Guptill, for maintaining contact and good cooperation from local fishermen which enabled the survey to progress smoothly. Drs. R. Mohn and G. Robert kindly reviewed the manuscript.
