#### Abstract

The size-at-age and condition of cod in the offshore of Subdivision 3Ps were monitored by sampling catches during research bottom-trawl surveys in the winter/spring of 1972-1997. There are strong year effects in the size-at-age data that have not yet been explained. Peak length-atage occurred in the mid-1970s for young ages and progressively later to 1980 for older ages. From the mid-1980s to the late 1990s, length-at-age and weight-at-age varied with no trend (younger ages) or declined (older ages). Condition, as measured by somatic (gutted) weight and liver weight relative to length cubed, was low in fish sampled during the 1993-1997 surveys. However, there is no evidence that these values are unusually low because sampling was conducted in April when condition is near the low point of the seasonal cycle. There are few comparable data from previous years. During previous assessments of this stock, weights-at-age on January 1 were estimated from the mean weights-at-age derived from sampling of commercial catches. A preliminary investigation of the utility of using January 1 weights-at-age derived from the research sampling found that the research data were more variable than the commercial data and that estimates from research data tended to be much higher than those from commercial data during the 1970s and early 1980s.

## Résumé

La taille selon l'âge et le facteur de condition des stocks de morue dans la zone hauturière de la subdivision 3Ps ont fait l'objet d'un échantillonnage des captures à l'occasion de relevés au chalut de fond au cours de l'hiver et du printemps lors de la période de 1972 à 1997. Il y a de fortes incidences dans les données sur la taille en fonction de l'âge qui n'ont pas encore été expliquées. La longueur maximale en fonction de l'âge a été observée vers le milieu des années 70 pour les jeunes poissons et un peu plus tard jusqu'en 1980 pour les poissons plus âgés. Du milieu des années 80 à la fin des années 90 , la longueur et le poids en fonction de l'âge ont varié, sans révéler de tendance (poissons plus jeunes) ou de baisse (poissons plus âgés). Le facteur de condition, mesuré par le poids somatique (éviscéré) et le poids du foie par rapport à la longueur au cube était faible chez le poisson échantillonné au cours des relevés de 1993 à 1997. Toutefois, rien n'indique que ces valeurs étaient anormalement faibles parce que l'échantillonnage a eu lieu en avril, alors que le facteur de condition se situe près du point faible du cycle saisonnier. Il existe peu de données comparables des années précédentes. Au cours d'évaluations antérieures de ce stock, le poids en fonction de l'âge au $1^{\mathrm{er}}$ janvier était estimé d'après le poids moyen selon l'âge dérivé de l'échantillonnage de prises commerciales. Un examen préliminaire de l'utilité d'utiliser le poids selon l'âge au $1^{\text {er }}$ janvier dérivé d'un échantillonnage de recherche a permis de constater que les données de recherche étaient plus variables que les données commerciales et que les estimations à partir des données de recherche étaient beaucoup plus élevées que celles des données commerciales au cours des années 70 et au début des années 80 .

## Introduction

Cod (Gadus morhua) in several areas of Atlantic Canada experienced pronounced declines in growth and condition during the late 1980s and early 1990s (Sinclair 1996; Sinclair and Murawski 1997). The degree to which such changes occurred in the stock off the south coast of Newfoundland (Subdivision 3Ps) is difficult to assess because the DFO bottom-trawl surveys have varied considerably in timing and there appear to be strong year effects in size-at-age data that have not yet been explained (Lilly MS 1996). The major purpose of this paper is to explore in more detail the size at age and condition data available from cod sampled during the surveys in 1972-1996 and to update the analyses with data collected in 1997.

A second purpose is to document the method used to calculate the January 1 weights-at-age used during the 1998 assessment of 3Ps cod (Stansbury et al. MS 1998). The relative merits of commercial data and research vessel data are discussed, and the reasons for continuing to use commercial weights-at-age at this time are described.

## Materials and Methods

## Research vessel surveys

## Survey design

Cod were caught during stratified-random bottom-trawl surveys conducted in Subdivision 3Ps during winter-spring 1972-1997. The timing of the surveys varied considerably, with the earliest and latest dates of fishing being January 27 in 1988 and June 12 in 1975 (Table 1). The median dates of fishing varied from February 7 to June 6 . The number of fishing stations also varied considerably, from a low of 44 in 1978 to a high of 159 in 1983. The number of stations tended to be lower in the 1970s and early 1980s. Note that there were two surveys in 1993, one in February and one in April. Only the latter has been included in the time-series.

The survey gear was changed twice during the period 1972-1997. The 51 m side trawler 'A. T. Cameron' (1972-1982) deployed a Yankee 41.5 otter trawl, the sister 50 m stern trawlers 'Alfred Needler' $(1983,1984)$ and 'Wilfred Templeman' (1985-1995) deployed an Engel 145 Hi-Lift otter trawl, and in 1996-1997 the 'Wilfred Templeman' deployed a Campelen 1800 shrimp trawl with rockhopper foot gear. In all instances, a 29 mm mesh liner was inserted in the codend. In 1972-1995, tows were made at 3.5 knots for 30 min at each fishing station, whereas in 19961997 tows were made at 3.0 knots for 15 min . Catches from the few stations of non-standard duration were appropriately adjusted. Fishing in all years was conducted on a 24-h basis.

Fishing stations were allocated randomly within strata that had been designed by defining depth zones and then subdividing these zones perpendicular to the bathymetry. The number of fishing stations allocated to each stratum was roughly proportional to the size of the stratum, with the
constraint that each stratum be allocated no fewer than 2 stations. (There were instances in which the sampling objectives were not realized.) Doubleday (1981) provides illustrations of the strata and information on their areas and depth-ranges. Several additions and modifications to the stratification scheme are described by Bishop (MS 1994) and Murphy (MS 1996). Additional strata were added to the inshore in 1997. Many analyses, including sequential population analysis, make use of only those strata that have been fished over a long time period. These have been termed index strata. Strata 293-300, 709-710, and 776-783 are excluded from the index strata. Only data from sets in the index strata are included in the analyses presented in this paper.

## Biological sampling

Sampling of cod for otoliths and various biological attributes was conducted using two distinct procedures (Table 2). The first involved determination of biological attributes (eg. fork length, cm ) and the extraction of otoliths at sea. The second, which was started in 1978, involved the determination of body length at sea followed by the freezing of the fish for detailed examination in the laboratory at the Northwest Atlantic Fisheries Centre, St. John's. These frozen fish were thawed in fresh water and weighed (to the nearest 10 g ) before being cut (round weight) and again after removal of the organs from the abdominal cavity (gutted weight). The liver and gonad were also weighed (g) or measured volumetrically (ml).

For each of these two methods of sampling, there were several changes in what constituted a sample and several changes in the biological attributes measured. With respect to the sampling of unfrozen fish, a single sample was obtained for the whole Subdivision during 1972-1984, two samples were obtained during 1985-1987, and a single sample was obtained in 1988-1996. With respect to the sampling of frozen fish, a single sample was obtained for the whole Subdivision during 1978-1984, two samples during 1985-1988, three samples during 1989-1993 (February), four samples in 1993 (April) and five samples in 1994-1997. The boundaries of the sample areas varied over time, and in some years (notably 1985-1988) several strata were not included in any of the samples.

For the period 1978-1984, all information regarding body weight and the size of individual body parts came only from the frozen fish. Additional information was collected at sea starting in 1985. From 1985-1989, the volumes of the liver and gonad were determined with volumetric cylinders for all fish sampled at sea. In 1990, balances for weighing at sea were used to obtain round weight, gutted weight, and weights of large livers and gonads for all fish sampled at sea. The sizes of small ( $<100 \mathrm{~g}$ ) livers and gonads continued to be determined volumetrically. In 1991 and subsequent years, weights were obtained for livers and gonads of all sizes. An important change for the frozen fish, initiated in 1991, was the determination of round weight at sea prior to freezing.

The number of aged fish for which body length, body weight and liver size (weight or volume) were determined in each year is recorded in Table 3. The number of fish for which both length and age were determined is given by year and age in Table 4. The number of fish sampled at the older ages declined during the late 1980s and 1990s. The number sampled at age 1 increased
dramatically with the introduction of the Campelen trawl in 1996. The number of fish sampled for weight in addition to length and age is given by year and age in Table 5.

## Data analysis

All sampling was stratified by length, so calculation of mean length, weight and condition at age included weighting observations by population abundance of the size groups (Morgan and Hoenig 1997), where the abundances were calculated by areal expansion of the stratified arithmetic mean catch at length per tow (Smith and Somerton 1981). Note that weights were not obtained prior to 1978 and that in 1978-1989 the number of aged fish for which weight was recorded was substantially fewer than the number for which length was recorded.

The somatic condition and liver index of each fish were expressed using Fulton's condition factor $\left(\left(\mathrm{W} / \mathrm{L}^{3}\right)^{*} 100\right)$, where W is gutted weight $(\mathrm{kg})$ or liver weight $(\mathrm{kg})$ and L is length ( cm ). Note that somatic condition as defined in this paper differs from that proposed by Dutil et al. (MS 1995), who use somatic weight calculated as total weight minus gonads and stomach contents. This formulation cannot be applied directly to data collected from 3Ps cod because the weight of the empty digestive tract was not determined. Note that there may be merit in considering the sizes of the carcass (gutted weight) and the liver separately, since these two body compartments may differ in their responses to food deprivation and intensive feeding. In addition, the liver index used in this paper differs from the hepato-somatic index proposed by Dutil et al. (MS 1995). For the liver index in this paper the liver weight is expressed relative to body length, in a manner identical to the calculation of somatic condition, whereas for the hepato-somatic index of Dutil et al. (MS 1995) the liver weight is expressed relative to somatic weight. A concern with the latter formulation is that body components other than the liver may vary in weight. Hence, for a fish of given length, changes in muscle mass will cause changes in hepato-somatic index (as defined above) even if there is no change in liver weight.

## Results and Discussion

## $\underline{\text { Size at age }}$

Mean lengths-at-age (Table 6; Fig. 1) varied over time. For the period 1972-1997, peak length-at-age occurred in the mid-1970s for young ages (3-4) and progressively later to 1980 for older ages. From the mid-1980s to 1997, length-at-age varied with no trend (younger ages) or declined (older ages).

It would be instructive to determine if some of the variability in length-at-age can be accounted for by variability in population size or environmental temperature. However, there are some unexpected year effects in the length-at-age data (Fig. 2; see also Fig. 4 in Lilly MS 1996). There appears to be negative growth for at least 2 cohorts during each of the intervals 1977-1978, 19801981, 1989-1990 and 1993-1994. Apparent negative growth could result from underrepresentation of the larger fish within a cohort. This could be caused by relatively high mortality of larger fish or lower availability of larger fish. The latter could occur either because a
higher proportion of the larger fish occur outside the survey area or because larger fish are less susceptible to capture by the gear. Apparent negative growth could also result if the survey area contained different "groups" of fish with different growth rates, and the proportion of each group in the sampling varied from year to year. There is good evidence that the 3Ps stock consists of several stocks or substocks, but it has not yet been determined whether these smaller units experience different growth rates. There is also a possibility that the degree of inclusion of adjacent stocks may vary from year to year. For example, the degree to which 3Pn4RS cod occur within 3Ps probably varies among years (D'Amours et al. MS 1994), and Pinhorn (1969) reported that cod from Burgeo Bank (western 3Ps) grow faster than those from 3Pn. There may also be annual variability in the presence of 3 NO cod, which grow relatively quickly (Fleming 1960).

The changes in mean weights-at-age (Table 7; Fig. 3) appear very similar to those for mean lengths-at-age, but will not be examined further in this paper because there is evidence that the weight of both the muscle mass and the liver undergo changes during the winter-spring period.

## Cod well-being

Mean somatic (gutted) condition at age (Table 8; Fig. 4) was variable from 1978 to 1986, relatively constant from 1986 to 1992, and dropped suddenly in 1993 before rising to an intermediate level in 1995-1997. Because condition calculated with Fulton's formula increases with body length, and length-at-age has declined over time, condition at length (Fig. 4B) might be a better indicator of changes in condition over time. As demonstrated by Lilly (MS 1996), much of the annual variability is related to the timing of the surveys. When mean condition in each of three length groups was plotted against the median date of sampling during the survey, there is a gradual decline in condition from the earliest median date (Feb. 7) to approximately mid-April, after which there is an increase. The time course of changes from late April onward is poorly defined because of the paucity of observations.

Mean liver index at age (Table 9; Fig. 5) had a pattern similar to that seen in condition, except that the 1983 values were more clearly at higher levels than other years in the early 1980s and there was a more pronounced peak in the late 1980s and early 1990s. When the values for specific size groups were plotted against the median date of sampling, there was a very pronounced decline in liver index during winter and early spring.

The low condition values observed in recent years (1993-1997) are mainly a consequence of sampling near the low point of the annual condition cycle. They are not indicative of a large and persistent decline in well-being. It is difficult to determine if condition during these years was near normal for the time of year because there are very few data from earlier years with which the recent values can be compared. In the most recent three years there has been some increase from the low values in somatic condition observed in 1993-1994.

## Commercial weights-at-age

Mean weights-at-age of the cod caught in the commercial fishery (including food fisheries and sentinel surveys) in Subdivision 3Ps in 1959-1995 are provided in Table 7 of Shelton et al. (MS 1996). Comparable data for 1996 and 1997 are provided in Tables 5 and 8 of Stansbury et al. (MS 1998). The full matrix, including revisions for 1992 and 1994, is provided in Table 10. There are two aspects of these data that should be noted. (1) A single weight-at-age vector has been used for the years 1959-1976. The derivation of this vector is not known at this time. The weight at age 3 in this vector is low compared to all values subsequent to 1976 and may be more representative of the weight of age 3 fish in the population, because the fishery probably selects for the largest fish at age 3. (2) There is a missing value for age 14 fish in 1995. It was arbitrarily decided to set this equal to the mean of the two preceding and two following years.

Exploration of the consequences of various catch options in 1998 requires estimates of the weights-at-age in the commercial catch in 1998 and weights-at-age in the population at the beginning of 1998 and 1999. Since 1997 was the only year since 1993 to see a substantial fishery, it was assumed that the mean weights-at-age in the 1997 fishery would provide the best estimates of the mean weights-at-age in the 1998 fishery (Table 10).

## Weights-at-age at the beginning of the year

Estimation of population biomass at the beginning of the year requires an estimate of the mean weight-at-age at the beginning of the year. These mean weights have usually been obtained by adjusting to the beginning of the year those mean weights-at-age calculated from sampling during the commercial fishery (see, for example, Rivard 1982, p. 14). There are several problems associated with this approach. First, the commercial fishery may be conducted with a variety of gears, each with its peculiar selection pattern. The size-at-age determined from sampling the catch from any specific gear may not reflect size-at-age in the population. Second, the relative contribution of each gear to the total catch may vary among years. Third, the temporal pattern of fishing may not centre on the time when the fish attain the mid-point of their annual length increment. Fourth, the temporal and spatial pattern of fishing may vary among years. Prior to preparation of the 1998 assessment of 3Ps cod it was thought that weights-at-age calculated from samples collected during research bottom-trawl surveys should be investigated to determine if they provide a more representative measure of weight-at-age at the beginning of the year.

Data from the surveys are not without problems. First, the weights-at-age are available only since 1978 and are based on small sample sizes for many combinations of year and age (Table 5). Second, the surveys were conducted 2-6 months after January 1 (Table 1) and there is currently no model of seasonal growth from which survey weights-at-age can be extrapolated back to January 1.

Because of these problems with survey weights-at-age, it was decided to explore the possibility of deriving January 1 weights-at-age from information on lengths. This would take advantage of the fact that information on length-at-age is available since 1972 and is often based on larger sample sizes than the corresponding data for weights (compare Tables 4 and 5). The problem of
extrapolation back to January 1 was side-stepped by assuming that the cod do not increase in length between January 1 and the date of each survey. The evidence for this is weak. First, Pinhorn (1966) reported that otolith growth of west Newfoundland cod, caught off southwestern Newfoundland, starts in July and continues until December. Second, condition (somatic condition and liver index) of cod both offshore (this paper) and inshore (Lilly MS 1996) decreases during winter-spring, and it is unlikely that linear growth would occur while condition was declining. Third, average spawning time for cod on St. Pierre Bank is mid-May (Hutchings and Myers 1994), and again it is unlikely that linear growth would occur in mature cod at a time when they put considerable energy into reproductive products. Even if length does not change between January 1 and the time of each survey, there is still the problem of the decline in weight at length. For this exercise, it was assumed that the weight at length could be approximated from a weight - length relationship calculated from data collected as close as possible to the start of the year. Data collected in 1988-1991, when the surveys were conducted primarily in February (Table 1), were used to obtain the predictive equation

$$
\log _{10}(\text { weight })=3.1747 * \log _{10}(\text { length })-5.3729,
$$

where weight is in kg and length is in cm . The equation is based on 1907 fish with a length range of $13-141 \mathrm{~cm}$. The weight of each individual fish sampled for length ( cm ) and age was estimated from this regression equation and mean weight-at-age was estimated as described above.

These research January 1 weights-at-age, which are highly preliminary and merely illustrative, may be compared with January 1 weights-at-age calculated from commercial weights-at-age (Table 10) using formulae in Rivard (1982, p. 14). For ages 4-14, weight-at-age i at the beginning of year $t\left(W_{i, t}\right)$ was approximated by

$$
W_{i, t}=e^{\left(\ln W_{i-0.5, t-0.5}+\ln W_{i+o .5, t+0.5}\right) / 2}
$$

For age 3 , the $\mathrm{W}_{\mathrm{i}, \mathrm{t}}$ were approximated by the relationship

$$
W_{i, t}=e^{\left(2 \ln W_{i+0.5, t+0.5}-\ln W_{i+1, t+1}\right)}
$$

The resulting estimates of January 1 weights-at-age are provided in Table11.

The degree of similarity between the research and commercial estimates of January 1 weights-atage was explored visually. On average over the period 1977-1997, the estimates from research sampling were lower than estimates from commercial sampling at ages 3 and 4 and higher than the commercial estimates at older ages (Fig. 6). When temporal changes in the two series were compared on an age by age basis (Fig. 7), it was clear that the research values were more variable. The coefficient of variation of mean weights-at-age at ages 3 to 12 tended to be in the range $15-35 \%$ for research data but only $8-17 \%$ for commercial data. In addition, there was no consistent relationship between the two series. That is, for a given age, the research estimates were not consistently either above or below the commercial estimates. However, there was a
tendency for the research weights-at-age to be considerably greater than those derived from commercial data during the 1970s and early 1980s. This phenomenon requires additional study.

At this time it is not clear that January 1 weights-at-age derived from research vessel samples are more representative than those derived from commercial sampling. There are strong unexplained year effects and there is no model of seasonal changes in weight-at-age that would allow extrapolation from the date of each survey back to January 1. Estimates from commercial data have been used in previous assessments of this stock, and it is prudent to continue to use those until it can be demonstrated that more representative estimates are available.

For exploration of the consequences of various catch options in 1998, mean weights at ages 4-14 at the beginning of 1998 (Table 11) were estimated using the commercial weights-at-age in 1997 and assuming that commercial weights-at-age in 1998 would be identical to those in 1997 (Table 10). The mean weight at age 3 at the beginning of 1998 was assumed to be the same as the mean weight at age 3 at the beginning of 1997. All mean weights-at-age at the beginning of 1999 were assumed to be unchanged from mean weights-at-age at the beginning of 1998.

${ }^{\text {a }}$ This survey is not considered to be part of the time-series. The survey time was changed to April to reduce the chances of catching cod from the 3Pn4RS stock.

Table 2. Instructions for sampling cod during bottom-trawl surveys in Subdivision 3Ps in 19721997. The instructions were extracted from unpublished trips reports available in the library of the Northwest Atlantic Fisheries Centre, St. John's, NF. In each of the sample descriptions, the numbers in parentheses are stratum numbers.

| Year | Trip | Sampling the unfrozen fish | Sampling of frozen fish |
| :---: | :---: | :---: | :---: |
| 1972 | ATC 197 | For the Subdivision, collect otoliths from cod $<32 \mathrm{~cm} ; 5$ per 3 -cm group cod $33-62 \mathrm{~cm}$; 15 per $3-\mathrm{cm}$ group cod $63-101 \mathrm{~cm} ; 30$ per 3 - cm group cod 102-116 cm; 15 per 3-cm group cod $>116 \mathrm{~cm}$; 5 per $3-\mathrm{cm}$ group |  |
| 1973 | ATC 207 | As in 1972 |  |
| 1974 | ATC 221 | As in 1972 |  |
| 1975 | ATC 234 | As in 1972, except for cod $33-62 \mathrm{~cm} ; 30$ per 3-cm group |  |
| 1976 | ATC 247 | For the Subdivision, collect otoliths from 25 specimens per $3-\mathrm{cm}$ group |  |
| 1977 | ATC 261 | As in 1976 |  |
| 1978 | ATC 273 | As in 1976 | For the Subdivision, freeze 5 specimens per 3-cm group |
| 1979 | ATC 287 | As in 1976 | As in 1978 |
| 1980 | ATC 302 | For the Subdivision, collect otoliths from 25-30 specimens per 3 -cm group | As in 1978 |
| 1981 | ATC 316 | As in 1976 | As in 1978 |
| 1982 | ATC 330 | As in 1976 | Instructions not recorded, but sample obtained |
| 1983 | AN 9 | As in 1976 | As in 1978 |
| 1984 | AN 26 | As in 1976 | As in 1978 |

(cont'd)

Table 2 (cont'd)

| Year | Trip | Sampling the unfrozen fish | Sampling of frozen fish |
| :---: | :---: | :---: | :---: |
| 1985 | WT 26 | For each of two samples, collect otoliths from 25 specimens per 3-cm group. <br> Samples are: <br> (1) Burgeo Bank (306-309) <br> (2) St. Pierre Bank (all other strata, but excluding 714-716) <br> For each sampled fish, also obtain: volume of liver volume of gonad | For each of two samples, freeze 5 specimens per 3-cm group. <br> Samples are: <br> (1) Northwest St. Pierre Bank (310-312) <br> (2) Halibut Channel $(315,318,319)$ |
| 1986 | WT 45 | As in 1985 | As in 1985 |
| 1987 | WT 55, 56 | As in 1985 | For each of two samples, freeze 5 specimens per 3-cm group. <br> Samples are: <br> (1) Northwest St. Pierre Bank (310-314) <br> (2) Burgeo Bank (306-309) |
| 1988 | WT 68 | For the Subdivision, collect otoliths from 25 specimens per 3-cm group <br> For each sampled fish, also obtain: volume of liver volume of gonad | As in 1987 |
| 1989 | WT 81 | As in 1988 | For each of three samples, freeze 5 specimens per 3-cm group. <br> Samples are: <br> (1) Northwest St. Pierre Bank (310-314) <br> (2) Burgeo Bank (306-309) <br> (3) Green Bank - Halibut Channel (east of 55010' W) |
| 1990 | WT 91 | For the Subdivision, collect otoliths from 25 specimens per 3-cm group <br> For each sampled fish, also obtain: <br> round weight <br> gutted weight <br> weight of liver (volume if liver <100 g) <br> weight of gonad (volume if gonad <100 g) | As in 1989 |

Table 2 (cont'd)

| Year | Trip | Sampling the unfrozen fish | Sampling of frozen fish |
| :---: | :---: | :---: | :---: |
| 1991 | WT 103 | For the Subdivision, collect otoliths from 25 specimens per 3-cm group <br> For each sampled fish, also obtain: <br> round weight <br> gutted weight <br> weight of liver <br> weight of gonad | As in 1989, except that in addition determine round weight at sea |
| 1992 | WT 118 | As in 1991 | As in 1991 |
| 1993 | WT 133 <br> (February) | As in 1991 | As in 1991 |
|  | WT 135 <br> (April) | For the Subdivision, collect otoliths from 10 specimens per $3-\mathrm{cm}$ group <br> For each sampled fish, also obtain: <br> round weight <br> gutted weight <br> weight of liver <br> weight of gonad | For each of four samples, freeze 5 specimens per 3-cm group. <br> Samples are: <br> (1) Northwest St. Pierre Bank (310-314, 705, 713) <br> (2) Burgeo Bank (306-309, 714-716) <br> (3) Green Bank - Halibut Channel (318, 319, 707-709) <br> (4) Remaining strata (315-317, 320-326, 706, 711, 712) |
|  |  |  | Determine round weights at sea |
| 1994 | WT 150, 151 | For the Subdivision, collect otoliths from 2 specimens per cm <br> For each sampled fish, also obtain: <br> round weight <br> gutted weight <br> weight of liver <br> weight of gonad | For each of five samples, freeze 2 specimens per cm Samples are: <br> (1) Northwest St. Pierre Bank (310-314, 705, 713) <br> (2) Burgeo Bank (306-309, 714-716) <br> (3) Green Bank - Halibut Channel (318, 319, 325, 326, 707-710) <br> (4) Placentia Bay (779-783) <br> (5) Remaining strata (315-317, 320-324, 706, 711, 712) |
|  |  |  | Determine round weights at sea |
| 1995 | WT 166, 167 | As in 1994 (However, instructions for WT. 166 specified 10 specimens per cm, whereas instructions for WT. 167 specified 2 per cm) | As in 1994 (Areas specified in instructions for WT. 167, but not for WT. 166) |
| 1996 | WT 186, 187 | As in 1994 | As in 1994 |

Table 2 (cont'd)

| Year | Trip | Sampling the unfrozen fish | Sampling of frozen fish |
| :---: | :---: | :---: | :---: |
| 1997 | WT 202, 203 | For the Subdivision, collect otoliths from 10 specimens per cm (This includes the fish taken in the frozen samples.) | For each of five samples, freeze 2 specimens per cm <br> Samples are: <br> (1) Northwest St. Pierre Bank (294-298, 310-314, 705, 713) |
|  |  | For each sampled fish, also obtain: <br> round weight <br> gutted weight | (2) Burgeo Bank (299-300, 306-309, 714-716) <br> (3) Green Bank - Halibut Channel (318, 319, 325, 326, 707-710) |
|  |  | weight of liver | (4) Placentia Bay (293, 779-783) |
|  |  | weight of gonad | (5) Remaining strata (315-317, 320-324, 706, 711, 712) |
|  |  |  | Determine round weights at sea |

Table 3. Sampling of cod caught during bottom-trawl surveys in Subdivision 3Ps in 1972-1997. Number of aged fish for which there are also records of length, body weight and liver size (weight or volume). Some entries differ from those in Table 2 of Lilly (MS 1996) because only data from successful survey sets in the index strata are included in the present analyses.

|  |  | Body weight |  |  | Liver |  |  |

Table 6. Mean length-at-age (cm) of cod sampled during DFO bottom-trawl surveys in Subdivision 3Ps in winter-spring 1972-1997. Entries in boxes are based on fewer than 5 aged fish. Some entries are different from those in Table 6 of Lilly (MS 1996) because only data from successful sets in the index strata are included in the present analyses.

| Age |  | 1972 | 1973 | 1974 | 1975 | 1976 |  | 1977 |

Table 10. Mean annual weights-at-age (kg) calculated from lengths-at-age based on samples from commercial fisheries (including food fisheries and sentinel surveys) in Subdivision 3Ps in 19591997. The weights-at-age from 1976 are extrapolated back to 1959. The 1997 data are extrapolated to 1998.

Fig. 1. Mean lengths at ages 1-10 of cod in Subdivision 3Ps in 1972-1997, as determined from sampling during DFO bottom-trawl surveys in winter-spring.

Fig. 2. Mean length (cm) at ages 1-12 of the 1962-1996 cohorts of Subdivision 3Ps cod, as determined from sampling during DFO bottom-trawl surveys in winter-spring.

Fig. 3. Mean round weight (kg) at ages 3-10 of cod sampled during DFO bottom-trawl surveys in Subdivision 3Ps in winter-spring 1978-1997.

Fig. 4. Mean gutted condition of cod sampled during DFO bottom-trawl surveys in Subdivision 3Ps in 1978-1997; (A) by age and year, (B) by length-group and year, and (C) by length-group and median date of collection.

Fig. 5. Mean liver index of cod sampled during DFO bottom-trawl surveys in Subdivision 3Ps in 19781997; (A) by age and year, (B) by length-group and year, and (C) by length-group and median date of collection.

Fig. 6. January 1 weights-at-age calculated from research and commercial sampling. (See text for details.) The values illustrated are the means of annual means for the years 1977-1997.

Fig. 7. Mean January 1 weights at ages 4, 6, 8 and 10 calculated from research and commercial sampling in the years 1972-1997.

[^0]:    ${ }^{\mathrm{a}}$ Instances where liver volume was measured but not liver weight.
