# The Status of Redfish in SA2+Div. 3K État du stock de sébaste de la souszone 2 et de la division 3 K 

D. Power<br>Department of Fisheries and Oceans<br>Science, Oceans and Environment Branch<br>P.O. Box 5667<br>St. John's NF A1C 5X1

#### Abstract

* This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations. * La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

Ce document est disponible sur l'Internet à:

#### Abstract

The highest reported catch from this stock was $187,000 \mathrm{t}$ in 1959. From 1961 to 1985 catches ranged between $15,000 \mathrm{t}$ to $56,000 \mathrm{t}$ and averaged about $27,000 \mathrm{t}$. Catches declined dramatically from about $29,000 \mathrm{t}$ in 1985 to 280 t in 1991 when directed fisheries essentially ceased. In 1997 the stock was put under moratorium to direct fishing which is still in effect. Catches averaged about 160 t from 1998-2000 and are primarily the result of bycatch discarded from shrimp fisheries in the NAFO Div. 2GHJ and 3 K areas. Approximately 2.5 million redfish in the length range from 5 cm to 19 cm were discarded during the 2000 shrimp fishery, which represents a relative exploitation of less than $1 \%$. Preliminary catch data for the 2001-2002 fishing year indicates 1,300 t have been taken in Div 2J in August by Russia and Lithuania. This catch was taken outside the 200 -mile limit utilizing large midwater trawls and is likely from the pelagic stock of redfish that resides primarily in the Irminger Sea. RV surveys indicate the population declined very rapidly over a ten-year period from 1980 to 1990. The relative exploitation rate generated from catches over this time period cannot totally account for the decline in the biomass. RV surveys continue to indicate the resource is at a very low level and there has been over 25 years of recruitment failure.

#### Abstract

Résumé C'est en 1959 que les plus fortes prises issues de ce stock, qui se chiffraient à 187000 t , ont été signalées. De 1961 à 1985 , elles se situaient entre 15000 t et 56000 t , atteignant une moyenne d'environ 27000 t , puis elles ont chuté en flèche d'environ 29000 t en 1985 jusqu'à 280 t en 1991, lorsque les prises dirigées ont essentiellement pris fin. En 1997, le stock a été mis sous le coup d'un moratoire de la pêche dirigée, encore en vigueur. De 1998 à 2000 , les prises, rejetées à la mer, qui se chiffraient à quelque 160 t en moyenne, étaient essentiellement des prises accessoires de la pêche de la crevette dans les divisions 2GHJ et 3K de l'OPANO. Environ 2,5 millions de sébastes d'une gamme de longueurs s'étalant entre 5 et 19 cm ont été rejetés à la mer durant la pêche e la crevette de 2000, ce qui représente un taux d'exploitation relatif de moins de $1 \%$. Les données préliminaires sur les prises pour la saison de pêche 2001-2002 révèlent que la Russie et la Lituanie ont en pris 1300 t dans la division 2 J en août. Ces prises, récoltées à l'extérieur de la limite des 200 milles à l'aide de gros chaluts semi-pélagiques, proviennent probablement du stock pélagique de sébaste qui réside principalement dans la mer d'Irminger. Des relevés de NR indiquent que la taille de la population a diminué très rapidement sur une période de dix ans allant de 1980 à 1990. Le taux d'exploitation relatif généré par ces prises sur cette période de temps ne peut complètement expliquer le déclin de la biomasse. Les relevés de NR continuent d'indiquer que la ressource est à un très faible niveau d'abondance et que le recrutement a fait défaut pendant plus de 25 ans.

## INTRODUCTION

Three species of redfish are present in the Northwest Atlantic (Sebastes mentella, S. fasciatus and S. marinus [ $=$ S. norvegicus]). These three species are similar and are nearly impossible to distinguish by their appearance. They are not separated in the fishery, and they are managed together. The most abundant of these are Sebastes mentella and $S$. fasciatus.

This paper presents information relevant to the assessment of stock status to October 2001 and provision of advice for the April 1, 2002 to March 31, 2003 fishing year for redfish in NAFO Subarea 2 + Div. 3K.

## DESCRIPTION OF MANAGEMENT REGULATIONS AND THE FISHERY

## Management Regulations

The fishery has been under TAC regulation since 1974 when a $30,000 \mathrm{t}$. quota was implemented. The TAC was increased to 35,000 t in 1980 and remained at that amount until it lowered to $20,000 \mathrm{t}$ in 1991. The TAC decreased to $1,000 \mathrm{t}$ in 1994 and was reduced to 200 t in 1995 with the constraint that any directed fishing was to be conducted under a "scientific protocol". This remained in effect for 1996. In 1997 the stock was put under moratorium to directed fishing which has remained in effect ever since. During 1999 a shift was implemented from a calendar year based TAC to a fiscal year based TAC currently in effect from April 1, 2001 to March 31, 2002.

## Nominal Catch

The highest catch taken from this stock was $187,000 \mathrm{t}$ in 1959. Between 1961 and 1979 catches averaged about 30,000 t, ranging between 17,500 t and 56,000 t (Table 1, Fig. 1). From 1980-83 catches averaged $16,000 \mathrm{t}$, increased to about $27,000 \mathrm{t}$ from 19841986 in response to improved markets and declined thereafter. There has not been a persistent directed effort on this stock since 1990 when $2,400 \mathrm{t}$ were landed. Landings declined to 280 t in 1991, and have been less than 18 t in each year from 1992-2000. In addition, estimates of redfish bycatch discarded from shrimp fisheries in the area from Div. 2G to Div. 2K have ranged from 14 t in 1983 to 665 tons in 1990. In 2000 an estimated 91 tons of redfish were taken as bycatch and discarded in the shrimp fisheries within SA2+Div. 3K. Preliminary catch data for the 2001-2002 fishing year indicates $1,300 \mathrm{t}$ have been taken in Div 2J in August by Russia and Lithuania. This catch was taken outside the 200-mile limit utilizing large midwater trawls and is likely from the pelagic stock of redfish that resides primarily in the Irminger Sea.

Canada has accounted for most of the landings since the implementation of the 200mile economic zone in 1977 (Table 2, Fig. 2). The steady reduction since 1986 was due primarily to a major redirection of effort to other redfish fisheries by domestic fleets and there was no effort by foreign countries (Russia and Japan) fishing Canadian quotas since 1987.

Historically, catches were taken throughout the year (Table 3, Fig. 3). Prior to 1977 a higher proportion of the catch was taken the first half of the year (foreign vessels), but after 1977 a higher proportion came from the second half of the year (domestic vessels). In the 1980s, most of the landings were taken from Div. 3K (Table 1, Fig. 1). This was primarily due to the prevalence of external parasites in Div. 2J (see below). Throughout the existence of this fishery, the predominant fishing gear has been the bottom otter trawl.

## Industry Experience

A number of reasons have been cited for the substantial reduction in landings since 1986 according to Canadian companies which had a directed fishery for this stock. First there was the continuous complaint of parasite infestation (Sphyrion lumpi, an external copepod which attaches itself to the flesh), particularly in Div. 2J. In addition there is a bacterial infection of the skin which also renders them undesirable for the prime market. Secondly, according to veteran trawler captains of this fishery, concentrations of fish had diminished on their traditional fishing grounds. Finally the major Canadian stakeholder, National Sea Products, had diverted effort to other fisheries because of the viability of the Div. 2J3K fishery. In early 1995, National Sea Products conducted a short experimental fishery in Div. 3K on traditional redfish grounds. Although only a few sets were conducted the results were very poor and the area steamed over was considered a desert in terms of viable concentrations of redfish.

## AVAILABLE DATA

## Commercial Fishery Data

There has been very limited data available since 1990 when the directed fishery was considerably reduced. In the mid-1980s prior to the decline in catches the bulk of the directed fishery consisted of fish in the $28-40 \mathrm{~cm}$ range which correspond to ages from 10-20 years.

Length sampling of redfish bycatch discarded in shrimp fisheries in 2000 was available through the observer program. Abundance at length was estimated separately for two shrimp fleets, those vessels less than 500 gross registered tons (GRT) and the traditional large vessel fleet (500+ GRT). Set by set samples were adjusted to the turnout weight of the set, summed, then adjusted to the total redfish catch of the observed sets only. An abundance at length per ton of observed shrimp catch was derived to provide the basis for estimating the redfish removal based on the amount of shrimp landed for the year. The weight to length relationship used in estimating the final removals was derived separately for males and females from DFO surveys from 19971999 in Div. 2GHJ3K. These surveys use a Campelen 1800 shrimp trawl with a liner in the codend. The length-weight results were:

Wgt. in grams (males) $=0.000009581^{*}$ Forklength ${ }^{3.101663187}$
Wgt. in grams (females) $=0.000008845^{*}$ Forklength ${ }^{3.129168941}$

Bycatch sampling information:

|  | \# Sets |  |  | Redfish Catch (kg) |  |  |  | Shrimp Catch (tons) |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Fleet | Observed | Sampled | \% | Observed | Sampled | \% | Observed | Landed $^{\text {a }}$ | \% |
| $<500$ GRT | 1452 | 28 | 1.93 | 2502 | 28 | 1.12 | 3633 | 42651 | 8.52 |
| $500+$ GRT | 5904 | 116 | 1.96 | 48774 | 805 | 1.65 | 30178 | 43716 | 69.03 |

${ }^{\text {a }}$ Figures taken from Orr et. al. (2001) for shrimp areas 4-6 (within SA2+Div. 3K)
Based on this approach, an estimated 2.5 million redfish were discarded by the shrimp fleet in 2000. The length range was between 5 cm to 27 cm (Fig. 4). The bulk of the bycatch ( $80 \%$ ) came from the $12 \mathrm{~cm}-18 \mathrm{~cm}$ length range (fish approximately 4 to 6 years old).

## Research Survey Data

## Indices of Abundance

Stratified random groundfish surveys have been conducted in the fall in Div. 2J and 3K since 1977. These surveys generally cover strata to depths of 1000 m but have been extended to deeper water in 1996. Generally though, the abundance of redfish drops off sharply beyond 800 m in the slope area. The stratification scheme was redesigned for the 1993 survey to redefine stratum boundaries based on more recent information on depth soundings (Bishop, MS 1994). Although it is difficult to compare the results of certain strata to those previous to 1993, in general the total area of revised stratification is only slightly different from the previous scheme used from 1977-1992. Up until the autumn of 1995 these surveys were conducted with an Engels 145 high lift otter trawl with a small mesh liner ( 29 mm ) in the codend and tows planned for 30 minute duration. Starting with the autumn 1995 survey, a Campelen 1800 survey gear was adopted with a 12 mm liner in the codend and 15 minute tows utilizing SCANMAR. The Engel data were converted into Campelen equivalents units for this assessment. A comparison of the generated data with the original Engel data suggested overall trends in abundance were the same except that the relative measure of abundance estimated for the Campelen trawl conversions were higher (Power and Orr MS 2001).

The resulting indices of stock size suggest the population in Div. 2J and Div. 3K were at historically low levels in 1994. Although there have been rather large fluctuations between some years in the both series, there has been a decline in the Div. 2 J biomass index from about an average of about 485,000 t from 1978-1981 to an average of 6,000 t from 1992-1995 (Tables 4-5, Fig. 5). The Div. 3K biomass index suggests an even larger reduction from an average of $844,000 \mathrm{t}$ from 1978-1981 to an average of $4,600 \mathrm{t}$ from 1992-1995 (Tables 6-7, Fig. 5). Average catch per tow was less than 12 kg in Div. 2 J and less than 9 kg in Div. 3K since 1991 compared to an average of 245 kg and 210 kg respectively from 1978-1981 surveys. Survey biomass estimates for Div. 2J3K from 1995-2000 (average 32,000 t), are less than 5\% of the average from 1978 to 1990 (775,000 t) based on the converted Engel data.

Stratified random groundfish surveys have been conducted in Div. 2G and 2H sporadically since 1978. The information from these surveys prior to 1992 suggests that
density and survey biomass of redfish in these areas was relatively low when compared to surveys in Div. 2J3K conducted in equivalent years (Power and Atkinson MS, 1990). The more recent surveys from 1996-1999 with the Campelen gear suggest that the survey biomass index in Div. 2GH is slightly lower (average 23,000 t) than in Div 2J3K (average $32,000 \mathrm{t}$ for the combined area). However, the abundance is higher than in Div. 2J3K because on average smaller sizes were caught in the survey.

Greenland halibut directed surveys have also been conducted in Div. 3K in 1991, 1994 and 1995 during which redfish information was collected. The 1991 survey was a line transect survey conducted in September and the 1994 survey a stratified random design conducted in February-March. Both surveys covered depths from 750 m-1500 m . The 1995 survey, conducted in March-April was also stratified random but had more extensive coverage from $500 \mathrm{~m}-1500 \mathrm{~m}$. Trawlable biomass was estimated about 4000 t in the 1991 survey, primarily due to one large set and there were no redfish caught in the 1994 survey (Morgan et al MS 1994). The trawlable biomass from the 1995 survey was about 1700 t.

It had been suggested previously that the timing and coverage of the fall Div. 2J3K surveys may not be optimum to fully understand the dynamics of the stock because distribution plots of Div. 2J3K survey catches indicated that in some years large concentrations of fish were at the border of the surveyed area (Power and Atkinson MS 1990). The data from the Greenland Halibut surveys suggest that there was no large abundance of redfish missed because of distribution in deeper water in the 1991, 1993 and 1994 fall surveys to Div. 3K.

## Indices of Recruitment

Length distributions from the surveys in Div. 2J3K in terms of mean number per tow at length from Div. 2 J and 3 K surveys (Fig. 6) indicate that the stock is at a very low level and recruitment has been extremely poor since the year classes of the early 1970s. The age classes currently comprising the stock are primarily those born since 1990 in the length range from $16 \mathrm{~cm}-25 \mathrm{~cm}$. Included in this are two pulses of recruitment at 6 cm ( 2.5 inches) and 10 cm ( 4 inches) that correspond to the 1999 and 1997 year-classes respectively. However, abundance in the survey is very low for all size groups compared to the late 1970s surveys. The distributions also reveal a contraction in the size range. Prior to the mid-1980s, the surveys indicated a significant portion of the survey catch was comprised of fish greater that 30 cm . Since then, dramatic changes have occurred both in overall abundance and in the proportion greater than 30 cm .

## Estimation of Stock Parameters

## Exploitation rates

The impact of redfish bycatch from Div. 2GHJ3K shrimp fisheries was assessed by comparing the estimated numbers at length of fish discarded during 2000 to DFO survey abundance at length from the autumn 1999 survey as an estimate of the beginning of the year population numbers. Relative exploitation by length group was
generally less than $5 \%$ and over the entire range of the catch ( 5 cm to 27 cm ) was estimated to be less than $1 \%$ in 2000.

An approximation of an relative exploitation rate for the total redfish catch from all fisheries was derived by calculating a ratio of catch weight in year 'x' from Div. 2J3K to survey biomass from the fall surveys in year ' $x-1$ ' as an estimate of stock size at the beginning of the year. The results (Fig. 8) suggest that relative exploitation on this stock based on the Engel survey estimates has been above 9\% only in the period from 1984 to 1987 when it ranged from $12 \%-18 \%$. In general, relative exploitation has been below $7 \%$ no matter which survey estimates (Engel or Campelen converted) are used. These estimates are considered to be below the F0.1 level ( $\mathrm{F}=.12$ or 11\%) based on yield per recruit calculations from neighboring Div. 3LN (ANON 1989).

## SUMMARY AND PROGNOSIS

It is not possible to provide an estimate of the absolute size of this stock. The estimates of trawlable biomass from RV surveys in Div. 2J and Div. 3K combined indicate the population declined very rapidly over a ten-year period from 1980 to 1990. The relative exploitation rate generated from catches over this time period cannot totally account for the decline in the biomass even though there has been over 25 years of recruitment failure.

This stock remains at a very low level. Most of the abundance in the 2000 RV survey is composed of fish less than 25 cm (10 inches) which are typically immature ( Ni and Sandeman 1984). From a conservation point of view, exploitation of this stock is unjustifiable. There are no indications that the status of this stock will change in a positive way in the near future. Any good recruitment coming into this stock will need at least 10 years before it will start contributing to the spawning stock because of the relatively slow growth rate of redfish.

Note: Discards not included

Table 4. Mean number (upper panel) and weight (kg., lower panel) per standard tow from Canadian AUTUMN surveys in Div. 2 J . Number of successful sets in brackets,
$N S^{\prime}=$ unsampled strata. The data are Campelen trawl equivalent units based on a comparative fishing experiment with an Engel 145 otter trawl (see text).

2J Autumn 1978-1992

Table 5. Mean number (upper panel) and weight (kg, lower panel) per standard tow from Canadian AUTUMN surveys in Div. 2 J . Number of successful sets in brackets, 'NS' = unsampled strata. Data from 1993-1994 are Campelen trawl equivalent units based on a comparative fishing trials with an Engel 145 otter trawl (see text). The data from 1995 onwards are empiracal Campelen data. A revision of the stratification scheme based on improved depth charts was also implemented in 1993.

2J Autumn 1993-2000

Table 6. Mean number (upper panel) and weight (kg, lower panel) per standard tow from Canadian AUTUMN surveys in Div. 3K. Number of successful sets in brackets,
$N S^{\prime}=$ unsampled strata. The data are Campelen trawl equivalent units based on a comparative fishing experiment with an Engel 145 otter trawl (see text).

TK Autumn 1978-1992

3K Autumn 1993-2000

Fig. 1. Nominal catch of redfish in SA $2+3 \mathrm{~K}$ from 1961-2001 (provisional to Oct. 7). For 1980 onwards estimates of discards in shrimp fisheries occurring within SA2+ Div. 3 K are included where available.

Fig. 2. Nominal catch of redfish in SA 2+3K by country from 1961-2001 (provisional to Oct. 7) Country from 1961-2001 (provisional to Oct. 7)

Fig. 3. Nominal catch of redfish in SA 2+3K by month from 1961-1998.

Fig. 4. Estimates of redfish bycatch at length based on observer data from shrimp fisheries within SA2+Div 3K.

Fig 5. Survey indices of relative abundance for redfish in SA2 + 3K from autumn surveys. The 1978-1994 data for the Campelen series are converted data.

Fig. 6. Length frequency distribution from stratified-random research surveys to Div. 2J3K from 1978-2000. Plotted are mean number per standard tow. X-axis is forklength in cm. Data from 1978-94 are Campelen equivalent values.

Fig. 7. Estimates of relative exploitation of redfish bycatch from shrimp fisheries in SA2 + Div. 3 K in 2000 based on a ratio of numbers caught to RV survey abundance index from the 1999 autumn RV surveys in Div 2GHJ3K as beginning of year population numbers.

Fig. 8. Estimates of relative exploitation rate derived by calculating a ratio of catch in year ' $x$ ' in Division 2J3K to RV biomass index in year "x-1" from fall surveys.
