ASSESSMENT OF QUEBEC COASTAL WATERS WHELK STOCKS IN 2014

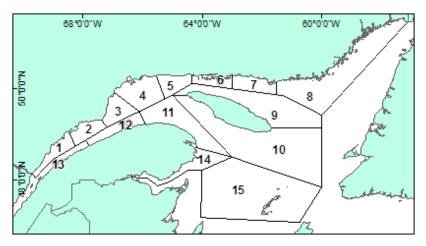

Figure 1: Whelk fishing areas in Quebec.

Source: DFO 2009

Context

The commercial whelk fishery began in the Estuary and Gulf of St. Lawrence in the 1940s. It expanded to the North Shore in the early 1990s and to the Îles-de-la-Madeleine in 2003. It has been more intensive in the Gaspé Peninsula–Lower St. Lawrence area since 2005. The whelk fishery is an inshore fishery, and it mainly uses coneshaped traps. It focuses primarily on <u>Buccinum undatum</u>, although some other species of <u>Buccinum</u> are present in the Estuary and Gulf of St. Lawrence. The fishery is regulated in all areas as to the number of licences, the number of traps and the minimum legal size of 70 mm. Quotas on landings are in place in Areas 1, 2, 11, 12, 13 and 15.

The resource is assessed every three years, and the last whelk stock assessment took place in winter 2012. The main indicators used for monitoring stocks are landings, fishing effort, catch per unit effort (CPUE) and size structure.

This science advisory report is from the March 10, 2015, meeting on the Assessment of the whelk fishery in the Quebec's inshore waters. Additional publications from this meeting will be posted on the <u>Fisheries and Oceans</u> Canada Science Advisory Schedule as they become available.

SUMMARY

- In 2014, whelk landings totalled 951 t in Quebec. A total of 87% of these landings were from the North Shore, 12% from the Gaspé Peninsula–Lower St. Lawrence and 2% from the Îles-de-la-Madeleine. Landings decreased in most fishing areas compared to 2011, and total allowable catches (TACs), when present, were not attained.
- In 2013 and 2014, the CPUE was above the reference average (from the 2001-2013 period) in Areas 1, 4 and 13, near average in Areas 2, 5, 6 and 8 and below average in Areas 3, 7, 12 and 15. In the latter four areas, the CPUE measured in 2014 was one of the lowest since 2001.
- Since 2011, average sizes have been fairly stable in all areas. In 2014 landings, the proportion of
 whelk smaller than the minimum legal size of 70 mm was less than 4%, except in areas 1 (10%)
 and 8 (19%). According to our data, the average size at which 50% of females are mature varies
 from 65 to 80 mm depending on the area. Harvesting immature individuals should be avoided.
- Area 10 is not fished, and fishing effort has been sporadic and low in Areas 9, 11 and 14. It is therefore impossible to comment on the status of the resource in these areas.
- In the period from 2012 to 2014, stock status indicators (CPUE and size structure) showed a positive trend in Areas 1, 4 and 13, were stable in Areas 2, 5, 6 and 8 and decreased in Areas 3 and 7. In Areas 12 and 15, the 2014 CPUE was very low. The considerable drop in CPUE in Area 15 was not anticipated given the performance of the fishery in 2013 and could be related to the atypical environmental conditions in summer 2014.
- In Areas 3, 4, 5, 8, 12 and 13, the number of traps used in 2014 was between 20 and 41% of the authorized number of traps under the current management measures. These various stocks may not be able to support the deployment of latent effort, especially in areas that are already fished in entirety.

BACKGROUND

The Waved Whelk, *Buccinum undatum*, is a gastropod mollusc found along the western Atlantic coast from New Jersey to Labrador, including the Estuary and Gulf of St. Lawrence. It is common in cold waters from the subtidal area (below the low water boundary) to depths of 30 metres or more. Whelk is a necrophagous predator. It feeds mainly on invertebrates such as polychaetes, molluscs and echinoderms. According to the literature, its life span is approximately 15 years. In the St. Lawrence, it can reach a shell height of 120-130 mm. Whelk can move quite fast (15 cm/min), covering several dozen metres when food or predators are present.

The sexes are separate. According to data collected in 2013 in three areas on the Upper North Shore (Areas 1 and 2) and the Îles-de-la-Madeleine, the sex ratio varies depending on the size of the whelk and the site. The sex ratio is fairly equal for whelk from 35 to 89 mm, but favours females in individuals ≥ 90 mm. Whelk ≥ 80 mm also have a high level of parasitism, between 34 and 46%, except for Baie-Comeau (Area 2), where it is 4%. The parasite, likely the castrating trematode *Neophasis sp.*, destroys the gonads, reducing the reproductive potential of this size class. The average size at which 50% of individuals reach sexual maturity varies depending on the sex and fishing area. It is generally greater for females. Our data show that the average size at maturity (minimum—maximum) for all fishing areas studied is 68.8 mm (58-80 mm) for males and 72.6 mm (65-80 mm) for females.

Whelk fertilization takes place internally. On the North Shore and the Gaspé Peninsula, the mating season occurs in May and June. The eggs are laid two to three weeks after mating, mostly in June and July. Egg-laying is generally collective; females assemble to lay eggs on one site. Eggs are enclosed in chitin capsules that are clumped together in a mass of several centimetres and attached to the

substrate. There is no planktonic larval stage. In the Estuary and Northern Gulf of St. Lawrence, juveniles emerge from the capsules after five to eight months of development (November to February) and are about 2-3 mm in size.

Whelk growth is fairly slow, and in Quebec the minimum legal size is reached after 6-7 years. Adults lead a rather sedentary life. They spend most of their time immobile and half buried in sediments. Evidence suggests that this behaviour, together with the absence of a larval phase, limits exchanges with adjoining populations and the possibility of rapidly recolonizing overexploited sites.

ASSESSMENT

There are 15 whelk management areas in Quebec waters. Areas 1 to 8 are along the North Shore, Areas 9 and 10 along Anticosti Island, Areas 11 to 14 along the Lower St. Lawrence and the Gaspé Peninsula, and Area 15 along the Îles-de-la-Madeleine (Figure 1). Area 10 has not been fished since 1997, and only certain fishers have fished for a few days in Areas 9, 11 and 14 in recent years. It is therefore impossible to determine the status of the resource in these areas. In recent years, there have regularly been less than five active fishers in Areas 2, 3 and 7, and occasionally in Areas 4, 5 and 13.

In 2014, there were 249 whelk licence holders in Quebec; however, only 69 of them were active (Table 1). Between 50 and 175 traps are authorized per licence. The total number of authorized traps for all licences in each fishing area varies between 550 and 6,400 traps, while the number of used or active traps is low, with 300 to 1,300 traps per fishing area. In 2014, the proportion of active traps was between 20 and 64% depending on the fishing area.

Table 1: Number of active licences, total number of licences issued, number of active traps, total number of traps authorized and percentage of active traps per fishing area in 2014.

	Fishing Area											
- -	1	2	3	4	5	6	7	8	12	13	15	
Active licences	6	3	3	6	4	9	3	13	9	4	7

Authorized traps	1,300	550	850	2,559	1,900	1,300	600	6,400	2,950	1,075	1,100	
Percentage of active traps ¹	58%	55%	41%	27%	29%	65%	67%	20%	32%	33%	64%	

¹ = number of active traps / total number of authorized traps x 100%.

Since 2005, the minimum legal size has been 70 mm everywhere in Quebec. The fishing season, which lasts six months in all fishing areas, extends from April or May to October or November. In Areas 1 and 2 on the North Shore, TACs of 491 and 109 t respectively were implemented in 2003. In the Gaspé Peninsula–Lower St. Lawrence, there have been TACs in Areas 11, 12 and 13 since 2010. They were set at 32, 135 and 82 t respectively over the past three years. In the Îles-de-la-Madeleine (Area 15), there has been a TAC since 2003, and it was 376 t from 2012 to 2014. None of the TACs were reached in 2014.

Whelk landings in Quebec peaked at 2,000 t live weight in 2003, when the fishery was introduced in the Îles-de-la-Madeleine (Figure 2). Subsequently, landings decreased, especially on the North Shore. Since 2006, landings have varied between 951 and 1,587 t (Table 1). In 2014, they were 951 t and 87% of them were from the North Shore, 12% from the Gaspé Peninsula—Lower St. Lawrence and 2% from the Îles-de-la-Madeleine. That same year, landings dropped by 24% on the North Shore, 25% in the Gaspé Peninsula—Lower St. Lawrence and 94% in the Îles-de-la-Madeleine compared to their respective reference averages. In most fishing areas, 2014 landings were also lower than in 2011, the last assessment year.

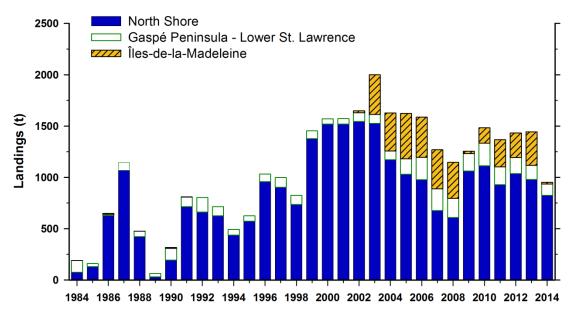

Figure 2: Whelk landings by region from 1987 to 2014.

Fishing effort reached a maximum value of 385,800 trap hauls in 2003 (Table 2). Effort then decreased, reaching 206,200 trap hauls in 2008. Effort has since varied between 173,100 and 261,900 trap hauls per year. In 2014, there were 173,100 trap hauls, a decrease in effort of 37% for the North Shore, 24% for the Gaspé Peninsula–Lower St. Lawrence and 79% for the Îles-de-la-Madeleine compared with their respective reference averages. The variations in landings by fishing area since 2006 are largely due to changes in fishing effort.

The average CPUE calculated based on logbooks is different in the different fishing areas (Table 4). Until recently, the highest CPUE was observed in the Îles-de-la-Madeleine, with a reference average (2003-2013) of 20.3 kg/trap. Elsewhere in Quebec, the average CPUE (2001-2013) is below 10.5 kg/trap. In 2013 and 2014, CPUE was above the reference average in areas 1, 4 and 13, near average in Areas 2, 5, 6 and 8 and below average in Areas 3, 7, 12 and 15. In the latter four areas, the CPUE measured in 2014 was one of the lowest since 2001.

Since 2004, DFO's commercial sampling program has provided information on the size (shell height) of landed whelk. Since 2006, the average size of landed whelk has remained stable or increased slightly (Table 5). In 2014, it was between 75 and 95 mm depending on the fishing area and was similar to or above its respective area reference averages. Since 2007, the percentage of landed whelk below the minimum legal size of 70 mm has generally been below 10% (Table 6). In 2014, the percentage of undersized whelk landed was below 4%, except in Areas 1 (10%) and 8 (19%). In Area 8, the percentage of undersized whelk landed has been the highest of all areas since 2009.

A research survey has been conducted every two years since 2005 in the Forestville, Pointe-aux-Outardes and Baie-Comeau sectors on the Upper North Shore (Areas 1 and 2). The surveys are conducted using a Digby scallop dredge and the four baskets are lined with 19-mm VexarTM netting. More than 99% of the whelk harvested belong to the *Buccinum undatum* species. Only a few *B. glaciale*, *B. scalariforme*, *B. totteni* and *Buccinum sp.* individuals have been found during the surveys. In 2013, the relative density of whelk \geq 20 mm (for all species of *Buccinum*) was from 0.1 to 135.6 individuals/100 m² depending on the site.

2004-2013 Average	15	25	1	4	6	5	5	31	4	9	4

The average whelk density by size, area and year and the average density and weight of egg masses are presented in Table 7. In Forestville, the density of legal-sized (≥ 70 mm) whelk was higher in 2013 than previous years. The density measured in 2013 in Pointe-aux-Outardes and Baie-Comeau was similar to previous years. In 2011, the density of young whelk (≤ 50 mm) was over 5 individuals/100 m² in all areas; in 2013, such a density was found only in Forestville. The size of landed whelk has varied from 9 to 112 mm since the first surveys in 2005.

Whelk egg masses were also assessed as part of these surveys. Egg mass density is higher in Pointe-aux-Outardes and Baie-Comeau than Forestville (Table 7). In 2013, there were 0.01 masses/100 m² in Forestville, 1.5 masses/100 m² in Pointe-aux-Outardes and 1.6 masses/100 m² in Baie-Comeau.

Table 7: Average density of whelk by size class and average density and weight of egg masses by area and year obtained during research surveys.

Sources of Uncertainty

Because of the absence of independent indicators for almost all fishing areas, such as those from research surveys, the advice for whelk is entirely dependent on the quality of the data from logbooks and from sampling of the commercial catch. Data that are partial or do not reflect reality (e.g., a trap haul different from that registered in the logbook) would affect indicator values. Since in several areas whelk fishing is a complementary activity, the fishing effort sometimes varies during the season and from year to year. The arrival of less-experienced fishers or the departure of experienced fishers can also affect catch rates. Environmental conditions such as water temperature at fishing sites can also affect the performance of the fishery. Consequently, the actual status of the resource could be different from our interpretation, and recommendations may not be completely aligned with reality.

CONCLUSION

Whelk is a sedentary benthic species that attaches its eggs to the substrate during the egg-laying period. Development continues on the egg-laying site, and there is no pelagic larval stage to help disperse the young. These biological characteristics make whelk vulnerable to local overfishing. The conservation principles implemented for whelk are designed to protect the reproductive potential of each population, or in this case, of each fishing area.

The main commercial fishery management measures (minimum legal size, fishing season, limited number of licences issued and traps authorized, TAC in certain areas) were adopted with the goal of improving fishery management and avoiding overfishing this resource.

The harvest of sexually immature individuals can have negative impacts on the resource. It is therefore recommended not to harvest them. In light of recent information, this conservation measure is even more important, since it seems that a significant percentage of whelk over 90 mm are parasited and no longer contribute to the population's reproductive potential. In several areas, the current minimum legal size protects only some sexually immature whelk, since the size at which 50% of females are mature is often greater than 70 mm.

In the period from 2012 to 2014, stock status indicators (CPUE and size structure) showed a positive trend in Areas 1, 4 and 13, were stable in Areas 2, 5, 6 and 8 and decreased in Areas 3, 7, 12 and 15. In the special case of Area 7, where the fishery is focused on only a small area, it would be beneficial to explore and expand the fishing ground. In Areas 12 and 15, the 2014 CPUE was very low. The considerable drop in CPUE in Area 15 was not anticipated given the performance of the fishery in 2013 and could be related to the atypical environmental conditions in summer 2014.

In Areas 3, 4, 5, 8, 12 and 13, the number of traps used in 2014 was between 20 and 41% of the authorized number of traps under the current management measures. These various stocks may not be able to support latent effort, especially in areas that are already fished in entirety.

OTHER CONSIDERATIONS

The current selectivity of the traps does not permit the harvesting of only legal-size whelk. Consequently, sorting is done on board vessels. In order to limit incidental mortality of sublegal-size whelk, it is important that they be handled with care and released back into the water as soon as possible and at the site where they were fished. It is recommended that selective fishing gear and methods for handling sublegal-size whelk on board vessels be developed and used.

Care must be taken when it comes to fishing effort (in number of traps) being concentrated on a single vessel. It is important for the fishing effort in a given fishing area to be distributed across the entire available area to reduce the danger of local overfishing. For a few years, buddying up licences has been authorized in certain fishing areas to reduce operating costs. We need to ensure that these

licences are active and that the fishing areas visited are not restricted to those of only one of the fishers involved. Distribution of the effort throughout a fishing area should also be considered when authorizing the use of several licences for a single captain and vessel.

The gastropod *Neptunea* is a toxic species occasionally found in small numbers in whelk traps (Figure 3). It is therefore important to inform fishers about returning this gastropod to the water to avoid cases of intoxication.
