## Acknowledgements

The surface drifter data described and displayed in this report were collected under two surface current research projects funded by the Program for Energy Research and Development (PERD) and Canadian Coast Guard New Initiative Funds (NIF). We thank Peter Smith, Erica Head, Murray Scotney, Richard Boyce, Ron Dawson, and the officers and crew of CSS Hudson and Canadian Coast Guard ships for help in the planning of the field program and deployment of the drifters. The Seimac drifters and data were provided by Canadian Coast Guard College through Étienne Beaulé and Ron Dawson. Ewa Dunlap and Yongsheng Wu gave helpful comments and suggestions on an early version of the report.

## **Abstract**

van der Baaren, A. and C. L. Tang. 2009. Satellite-tracked Surface Drifter Program: Scotian Shelf 2007 and The Gulf of St. Lawrence 2008-2009. Can. Data Rep. Hydrogr. Ocean Sci. 183: ix + 80 p.

Satellite-tracked surface drifters manufactured by MetOcean Data Systems Limited and Seimac Limited were deployed in the fall of 2007 and 2008 to collect surface current data. A total of 13 drifters were released from ships on the Scotian Shelf in 2007, and 23 in the Gulf of St. Lawrence in 2008. The data (position and sea surface temperature) were transmitted via the ARGOS system. The methods of data processing, error editing and calculation of surface velocities are described. It was found that the ARGOS data contained significant gaps including some greater than 12 hours. Many of the data gaps occurred near the changeover of the months or around midnight for specific days. Deployment sites, surface trajectories, time series of position, surface velocities, and sea surface temperature are displayed in graphic forms. Basic statistics of positions, velocities and sea surface temperature were compiled and tabulated. In 2007, the drifters tended to drift southeastward across the shelf for those that were tracked longer than 5 days. The 2007 Seimac drifters were only deployed for 5 days and all but one followed a southerly course during that time. The 2008 drifters in the Gulf of St. Lawrence, for the most part, traveled southeasterly to exit the Gulf of St. Lawrence via Cabot Strait.

## **Résumé**

van der Baaren, A. and C. L. Tang. 2009. Satellite-tracked Surface Drifter Program: Scotian Shelf 2007 and The Gulf of St. Lawrence 2008-2009. Can. Data Rep. Hydrogr. Ocean Sci. 183: ix + 80 p.

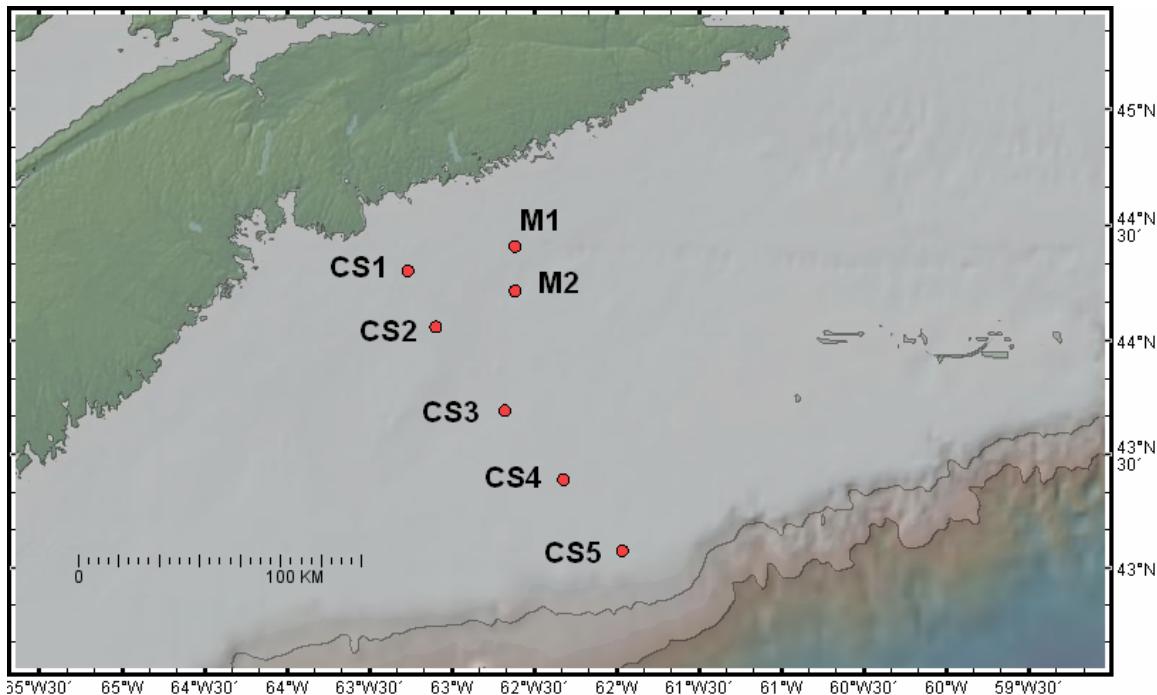

Des dériveurs de surface suivis par satellite, fabriqués par MetOcean Data Systems Limited et Seimac Limited, ont été déployés à l'automne 2007 et 2008 afin de recueillir des données sur les courants de surface. En 2008, des navires ont largué au total 13 dériveurs au-dessus de la plate-forme Néo-Écossaise et 23 dériveurs dans le golfe du Saint-Laurent. Les données (position et température de surface de la mer) ont été transmises au moyen du système ARGOS. Nous décrivons les méthodes utilisées pour le traitement des données, le traitement des erreurs et le calcul des vitesses superficielles. Nous avons constaté que les données ARGOS présentent d'importantes lacunes et que, dans certains cas, des données sont manquantes pour des périodes supérieures à 12 heures. Plusieurs de ces lacunes surviennent lors du changement d'un mois à un autre ou près de minuit selon des jours particuliers. Les lieux de déploiement, les trajectoires en surface, les séries chronologiques des positions, les vitesses superficielles et la température de surface de la mer sont représentés sous forme de graphiques. Les statistiques de base sur les positions, les vitesses et la température de surface de la mer ont été compilées et présentées sous forme de tableaux. En 2007, les dériveurs tendaient à

se déplacer vers le sud-est au-dessus de la plate-forme Néo-Écossaise, notamment ceux qui ont été suivis pendant plus de cinq jours. En 2007, le déploiement des dériveurs Seimac n'a duré que cinq jours et tous ces dériveurs, sauf un, ont suivi une trajectoire vers le sud pendant cette période. Les dériveurs déployés en 2008 dans le golfe du Saint-Laurent se sont déplacés vers le sud-est, pour la plupart, pour ensuite sortir du golfe par le détroit de Cabot.

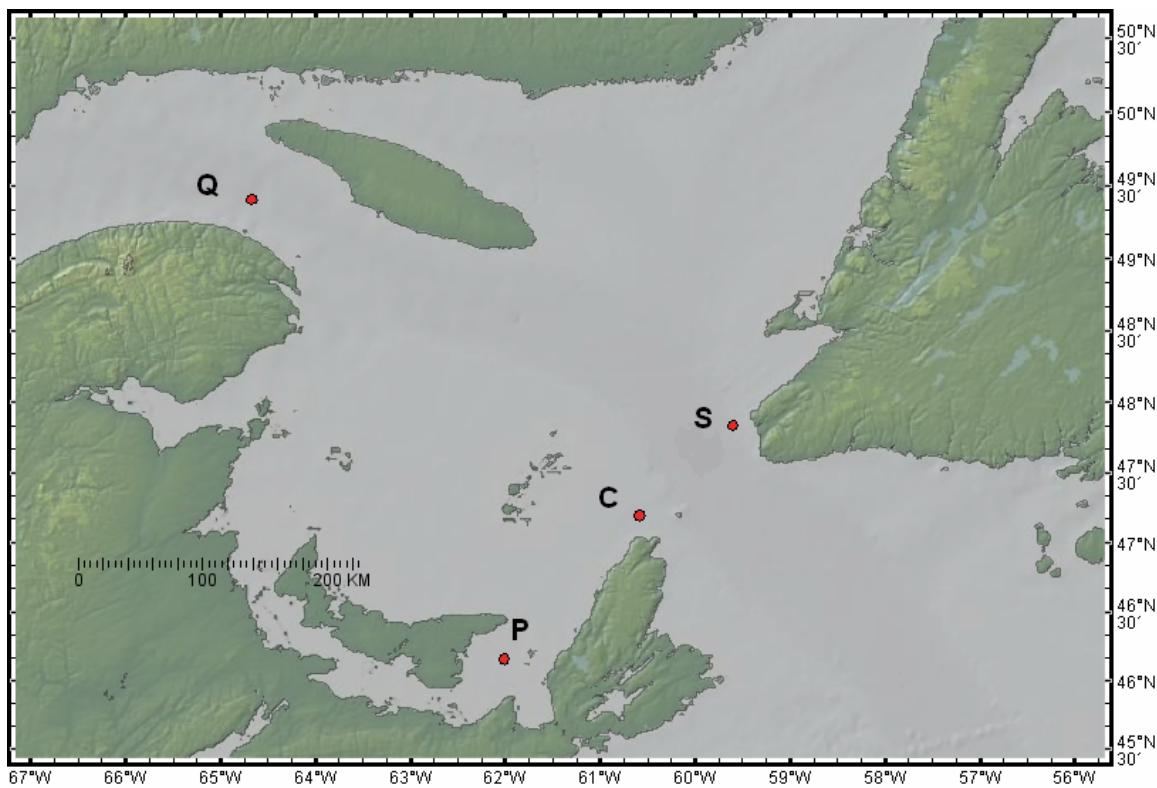

# 1 Introduction

As part of a surface current study, satellite-tracked surface drifters were deployed in eastern Canadian waters to collect surface current data. The purpose of the study is to use drifter data to calibrate and validate surface trajectories calculated from an ocean forecast model, Canadian East Coast Ocean Model, CECOM (Tang et al., 2007, 2008). The model data have been made available to users including Canadian Coast Guard for use in CANSARP (Canadian Search and Recur Planning), which is a planning tool for search and rescue operations.

Two validation trials were conducted. The first was conducted in October 2007 over the Scotian Shelf. Thirteen surface drifters were deployed at 7 sites along two lines offshore of Halifax during the fall cruise for the Atlantic Zone Monitoring Program (AZMP) aboard *CSS Hudson* (Figure 1). At each site, one or more drifters were released within a radius of 1 km. An Acoustic Doppler Current Profiler (ADCP) was moored at CS1, CS2 and CS3 at the time of the drifter release, and recovered six months later. The ADCPs collected current data in the water column which were used in model validation. The second field trial took place in October 2008 in the Gulf of St. Lawrence. Twenty-three surface drifters were deployed in 4 clusters from Canadian Coast Guard ships. Figure 2 shows the locations of the clusters indicated by “P”, “Q”, “C”, and “S”.

**Figure 1 Drifter deployment sites for 2007**

**Figure 2 Drifter deployment sites for 2008**

## 2 Procedure

Two types of surface drifters were used in the study: Self-Locating Datum Marker Buoy (SLDMB) manufactured by MetOcean Data Systems Limited, and Self-Locating Datum Marker Buoy (SLDMB) manufactured by Seimac Limited, both at Dartmouth, Nova Scotian. For the Seimac drifters, the Person-in-Water emulation mode was selected at the time of deployment. The data were transmitted via satellite for a maximum of one week. The MetOcean drifters had no set time limit for data transmission. They continued to transmit data until the battery ran out of power.

The drifters are equipped with Global Positioning System (GPS) receivers which give higher resolution positioning than can be provided by drifters who obtain positions from System ARGOS alone. System ARGOS (<http://www.argo-system.org>) satellites receive data transmissions when they pass overhead.

Data translation and error editing of data from the MetOcean drifters are described in the following sub-sections. Data from the Seimac drifters were processed by Canadian Coast Guard, which needed no translation or editing and were used directly upon receiving the files.

## **2.1 MetOcean drifters**

The MetOcean drifter has a cylindrical hull for the electronics, four vanes each measuring 50 cm by 70 cm with a foam float attached to it and an antenna above the hull. The drifters provide position data and sea surface air temperatures every half-hour. Similar drifters have been used to track ice drift (van der Baaren and Prinsenberg 2000a,b, 2001, 2006); the only difference being that the ice drifters provided hourly data.

Data were gathered every half hour and data messages were transmitted every 90 s. With these drifters, 3 hours of data are transmitted. Data messages are updated internally every time the drifter obtains new location fixes. When a System ARGOS satellite passes overhead several transmissions of the same data can be sent. This continues until the drifter “dies” (i.e. the battery dies, it sinks, is picked up by a passing fisherman, etc.).

Data transmissions include latitude, longitude, GPS time, GPS satellite constellation identification, data quality filters, and sea surface temperature. System ARGOS data that are downloaded contain not only the GPS information but also position information gathered by the ARGOS satellites. This ARGOS data are found in each transmission “header” line. The difference between the Position and SST and the ARGOS data is found in the frequency and accuracy: the Position and SST are more frequent and more accurate. The MetOcean manual states that the resolution is good to approximately 20 m within a  $\pm 91$  km range (MetOcean, 2004).

The MetOcean drifters deployed on the Scotian Shelf in 2007 remained afloat until mid-December in the case of 2 drifters but the others were active from the time of deployment to mid and late November.

## **2.2 Seimac position drifters**

The Canadian Coast Guard released 6 Seimac position-only drifters on the Scotian Shelf in 2007 and 14 in the Gulf of St. Lawrence in 2008. The drifter has a pyramid shaped float above the water line, an electronic unit underneath and a fishnet-type surface drogue tethered to the electronic unit. These drifters were active for 1 week and provided hourly position information only as gathered by ARGOS satellites. The data for these drifters are also presented in this report although they did not undergo the same preliminary translation and editing as the GPS drifters. The data were processed by the Canadian Coast Guard.

## **2.3 Data translation of MetOcean drifters**

Data were “translated” from the ARGOS data files archived by the Bedford Institute of Oceanography. Data arrived in monthly files sent by System ARGOS. The data were from October to December 2007 and from October 2008 to January 2009. From these files, three data files were created for each drifter: a data file that contained the GPS time series half-hourly data; a “header” file that contained ARGOS header position data; and a “dump” file that contained all data from all transmissions. The dump file acts as a direct data dump to check for transmission errors and translation errors.

The desired, final time interval of positions is half-hourly for the Position and SST. Due to the repetition of data transmissions (called “repeats”), as well as the drifter’s ability to store 3 hours of data, redundancy of data is very present. This redundancy can easily be seen by a single glance at just one dump file. Redundancy was handled through quality control filtering. Transmissions for a single half-hour during which no satellites were counted to obtain fixes were ignored because such transmissions give bad data. Data with values outside the range of possibilities for data listed in the MetOcean user manual were also ignored. All acceptable data for that half-hour time slot were given a single value by using the median value of those remaining data.

## **2.4 Error editing**

Data were edited “manually”. Position errors were easily spotted by plotting GPS latitudes and GPS longitudes for each drifter as time series and superimposing the ARGOS pass latitudes and longitudes from the headers of the ARGOS messages. Errors were also spotted by looking at discrete jumps in latitude or longitude within a short series of points. If the drifter appeared to move an “unreasonable distance” in a short time period then the data were examined for a lack of flow. Bad data were flagged and then deleted and interpolation was used to fill all the small data gaps as needed. Larger data gaps in the Position and SST (generally > 12 hours but sometimes as small as 6 hours) and gaps for which header data showed had a “non-linear” trend were filled with positions from the ARGOS message header. These header data were first smoothed with a moving average filter (5 point window) and then interpolated to half-hourly. Data gaps were most common in the 2008-2009 Gulf of St. Lawrence Position and SST and common just before midnight every day.

Because each drifter’s monthly data were translated separately there existed overlap at midnight of the last day of the month and early on the first day of the next month. This overlap is a repetition of one or two data transmissions but usually with fewer repeats. The repeated data found at the beginning of each month were deleted since including them and recalculating the median for those times did not make a significant difference.

Finally, data were linearly interpolated to fill smaller data gaps to give complete half-hourly time series of positions and measured surface temperatures.

## **2.5 Drifter drift**

To compute the drift velocities for the drifters two methods were used. One method computed a point-to-point difference and divided by the time interval between the two points to give an average velocity:  $\mathbf{U} = \Delta\mathbf{x}/\Delta t$  where  $\Delta\mathbf{x}$  is the distance between 2 longitudinal or latitudinal positions and  $\Delta t$  is the time interval (between every 6<sup>th</sup> position gives a 3 hour interval for Position and SST).

The other method computed an instantaneous velocity by finding the slope of the tangent to the curves traced by longitude and latitude data. In this case a moving window of N points was used such that a second degree polynomial was fit to the curve depicted

by these windowed data points. The first derivative of this polynomial provided the tangent line and the slope of this line gave the velocity at the mid-point of the window. The windows were moved by the number of points that would give the desired final time interval. For example, for the Position and SST the window would move by 6 points to give a final 3-hourly sampling interval. This method of computing drift velocities has the added advantage of smoothing data. Several window sizes were tried starting with an 8-hour window and decreased to the final accepted 3-hour window. The problem was that the larger windows tended to underestimate the drift speeds (especially prevalent for  $v$  – north-south component) when the instantaneous velocity components were compared to the average velocity components computed from point-to-point differencing.

### 3 2007 Scotian Shelf Drifters

The deployment information for the Scotian Shelf drifters (both MetOcean and Seimac drifters) is listed in Table 1 and the deployment sites are shown in Figure 3. Basic statistics for the 2007 deployment are given in Table 2.

Drift tracks for the 2007 drifters are shown in Figure 4. The general trend was for the drifters to drift southeast. Individual drifter drift tracks are presented in Appendix 1. Half-hourly time series of the positions and SST are given in Figure 5 to Figure 11 in Section 3.1.1. Hourly time series of the positions of the coast guard drifters are given in Figure 12 to Figure 17 in Section 3.1.2. The time axes for these coast guard drifter time series are in calendar days rather than in calendar dates. Drift time series (3-hourly) are in Figure 18 to Figure 30 in Section 3.2.

**Table 1 2007 Scotian Shelf deployment information**

### 3.2 2007 drifter drift

Basic statistics for 3-hourly drift speeds are given in Table 3. Statistics of drift speed were computed for components computed using the polynomial fit method. Data are lost at the beginning and the end of the complete drift record, depending on the size of the sampling interval and the statistics for drifter drift will reflect this. Table 4 gives the minimum, maximum, and mean of the measured sea surface temperature from the MetOcean drifters.

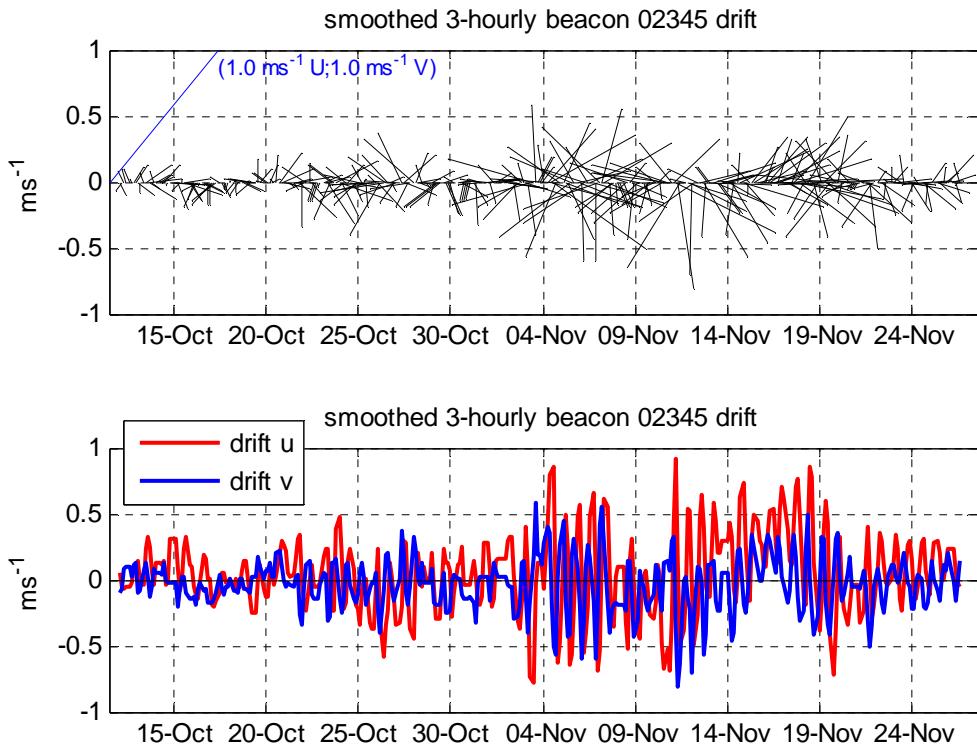

**Table 3 Basic statistics for 3-hourly drift velocity**

ID	total distance (km)	min U (m/s)	max U (m/s)	mean U (m/s)	min V (m/s)	max V (m/s)	mean V (m/s)

## 4 2008 Gulf of St. Lawrence Drifters

The deployment information for the drifters (both MetOcean and Seimac drifters) is listed in Table 5, and the deployment sites are shown in Figures 2, 31-36. Basic statistics for the 2008 deployment are given in Table 6.

**Table 5 2008 Gulf of St. Lawrence deployment information**

Drift tracks for the 2008 drifters are shown in Figure 32 for those that were released off the Gaspe Peninsula. Drift tracks for the 2008 drifters are shown in Figure 34 for those that were released off the Prince Edward Island in the eastern Northumberland Strait. Drift tracks for the 2008 coast guard drifters are shown in Figure 37 for those that were released in Cabot Strait. The general trend was for the drifters to drift to Cabot Strait and out onto the shelf. Individual drifter drift tracks are presented in Appendix 2.

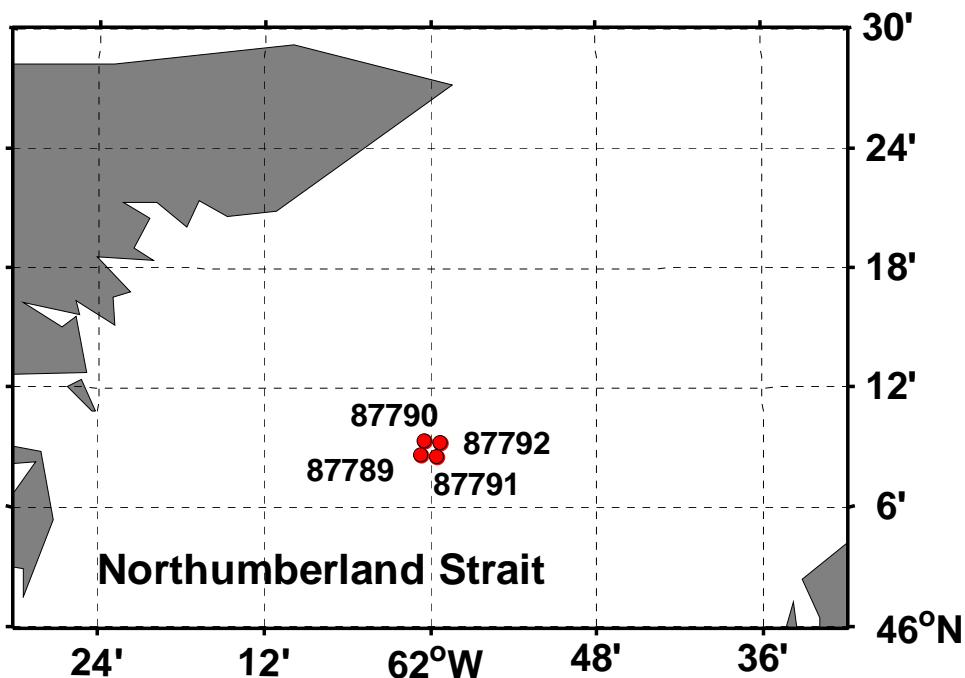

Half-hourly time series of the positions and SST are given in Figure 5 to Figure 46 in Section 4.1. Hourly time series of the positions of the coast guard drifters are given in Figure 47 to Figure 60 in Section 4.1. The time axes for these coast guard drifter time series are in calendar days rather than in calendar dates. Drift time series (3-hourly) are in Figure 61 to Figure 78 in Section 4.2. Drifter 87786 crashed into Anticosti Island on November 17 so the data were truncated to 12:30 pm on that day.

## 4.2 2008 drifter drift

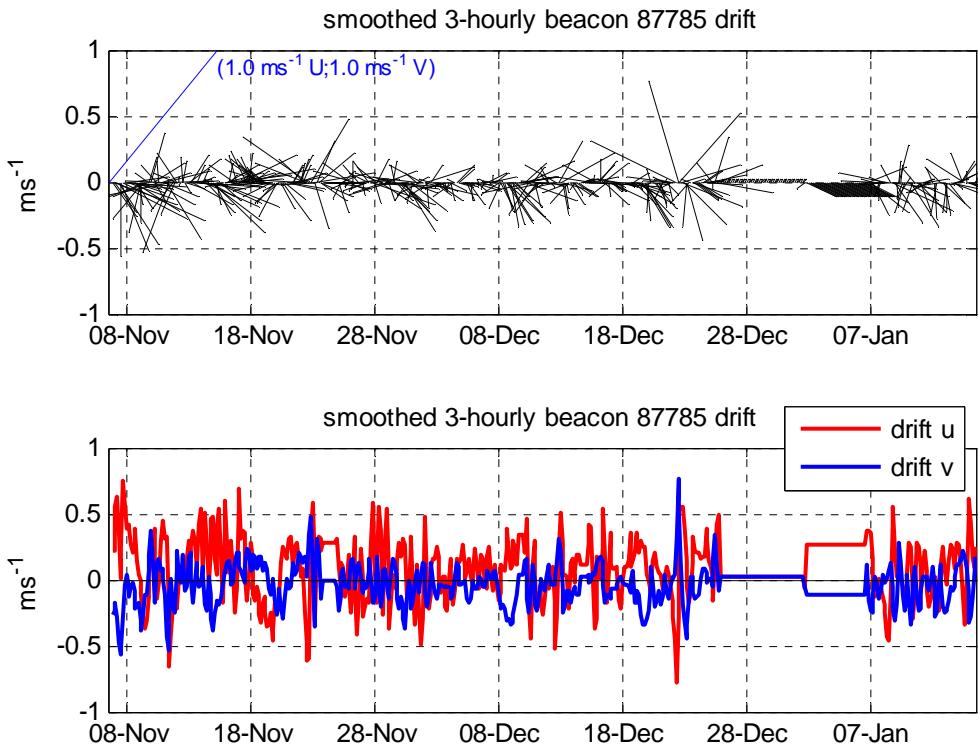

Drifters 87784, 17309, 17310, 17746, 17747, and 17748 were not used due to the brevity of their time series. Basic statistics for 3-hourly drift speeds are given in Table 7. Statistics of drift speed were computed for components computed using the polynomial fit method. Data are lost at the beginning and the end of the complete drift record, depending on the size of the sampling interval and the statistics for drifter drift will reflect this. Table 8 gives the minimum, maximum, and mean of the measured sea surface temperature from the MetOcean drifters.

**Table 7 Basic statistics for 3-hourly drift velocity**

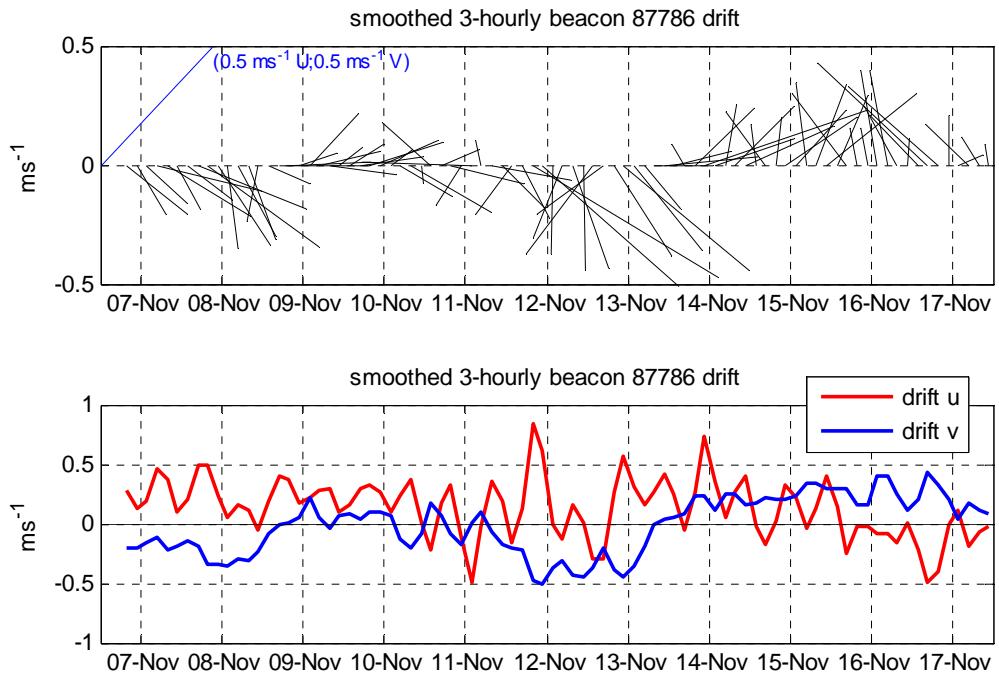

ID	total dist (km)	min U (m/s)	max U (m/s)	mean U (m/s)	min V (m/s)	max V (m/s)	mean V (m/s)

## 6 Appendix 1: Individual drifter drift tracks for 2007

Individual drifter drift tracks show the trace of the entire time series where each dot depicts every 6<sup>th</sup> point in the series (every 3<sup>rd</sup> hour for the MetOcean drifters and every 6<sup>th</sup> hour for the Seimac drifters).
