## **Canadian Data Report Of Hydrography and Ocean Sciences**

Data reports provide a medium for the documentation and dissemination of data in a form directly useable by the scientific and engineering communities. Generally, the reports contain raw and/or analyzed data but will not contain interpretations of the data. Such compilations commonly will have been prepared in support of work related to the programs and interests of the Ocean Science and Surveys (OSS) sector of the Department of Fisheries and Oceans.

Data reports are not intended for general distribution and the contents must not be referred to in other publications without prior written authorization from the issuing establishment. The correct citation appears above the abstract of each report. Data reports are abstracted in *Aquatic Sciences and Fisheries Abstracts* and indexed in the Department's annual index to scientific and technical publications.

Data reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out of stock reports will be supplied for a fee by commercial agents.

Regional and headquarters establishments of Ocean Science and Surveys ceased publication of their various report series as of December 1981. A complete listing of these publications is published in the *Canadian Journal of Fisheries and Aquatic Sciences*, Volume 39: Index to Publications 1982. The current series, which begins with report number 1, was initiated in January 1982.

## **Rapport statistique canadien sur l'hydrographie et les sciences océaniques**

Les rapports statistiques servent de véhicule pour la compilation et la diffusion des données sous une forme directement utilisable par les scientifiques et les techniciens. En général, les rapports contiennent des données brutes ou analysées, mais ne fournissent pas d'interprétation des données. Ces compilations sont préparées le plus souvent à l'appui de travaux liés aux programmes et intérêts du service des Sciences et levés océaniques (SLO) du ministère des Pêches et des Océans.

Les rapports statistiques ne sont pas destinés à une vaste distribution et leur contenu ne doit pas être mentionné dans une publication sans une autorisation écrite préalable de l'établissement auteur. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports statistiques sont résumés dans la revue *Résumés des sciences halieutiques et aquatiques*, et ils sont classés dans l'index annuel des publications scientifiques et techniques du Ministère.

Les rapports statistiques sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés sont fournis contre rétribution par des agents commerciaux.

Les établissements des Sciences et levés océaniques dans les régions et à l'administration centrale ont cessé de publier leurs diverses séries de rapports en décembre 1981. Une liste complète de ces publications figure dans le volume 39, Index des publications 1982, du *Journal canadien des sciences halieutiques et aquatiques*. La série actuelle a commencé avec la publication du rapport numéro 1 en janvier 1982.

## ABSTRACT

Ross, C.K., J.W. Loder and M.J. Graça. 1988. Moored current and hydrographic measurements on the Southeast Shoal of the Grand Bank, 1986 and 1987. Can. Data Rep. Hydrogr. Ocean Sci. No. 71: vi + 132 pp.

This report presents a statistical and graphical description of the moored data collected during the summers of 1986 and 1987 on the Southeast Shoal of the Grand Bank. The data were collected from moored current meters, thermistor chains, thermographs, and satellite communicating surface pressure/temperature buoys. Geostrophic winds computed by the Atmospheric Environment Service are also presented.

The presentation takes the form of record and monthly means, total and low frequency standard deviations, time series of the raw data and low pass filtered data, progressive vector diagrams and tidal analyses for current records, and spectra of all time series.

## RÉSUMÉ

Ross, C.K., J.W. Loder and M.J. Graça. 1988. Moored current and hydrographic measurements on the Southeast Shoal of the Grand Bank, 1986 and 1987. Can. Data Rep. Hydrogr. Ocean Sci. No. 71: vi + 132 pp.

Les auteurs décrivent du point de vue statistique et géographique les données recueillies à l'amarrage pendant l'été, en 1986 et en 1987, sur le haut-fond sud-est du Grand Bank. Les données ont été recueillies au moyen de courantomètres amarrés, de chaines de thermistances, de thermographies et de bouées de température/pression de surface reliées par satellite. Les auteurs décrivent aussi les vents géostrophiques calculés par le Service de l'environnement atmosphérique.

Le document contient les moyennes mensuelles et extrêmes, les écarts-types totaux et de faible fréquence, les séries temporelles des données brutes et les données après filtrage passe-bas, les diagrammes vectoriels évolutifs et les analyses de la marée pour les dossiers de courant, ainsi que les spectres de toutes les séries temporelles.

### Introduction

The climatological temperature distribution (fig. 1) shows that, during summer, the warmest bottom water on the entire Grand Bank occurs over the Southeast Shoal. In 1986, the Physical and Chemical Sciences Branch of the Department of Fisheries and Oceans initiated a physical oceanographic field study to describe the seasonal evolution of the bottom temperature feature, identify its origin, and infer the horizontal and vertical exchange rates over the Shoal from a heat budget for the feature's evolution.

In 1986 a pilot program (fig. 2) was conducted consisting of a current meter and thermistor chain mooring and surface temperature buoy near the centre of the Shoal, and Ryan thermograph moorings to the west and east. The mooring program was expanded in 1987 (fig. 2) to include current meter moorings to the west and east, Ryan thermograph moorings to the north and south, as well as the current meter and thermistor chain mooring and surface temperature buoy near the Shoal's centre.

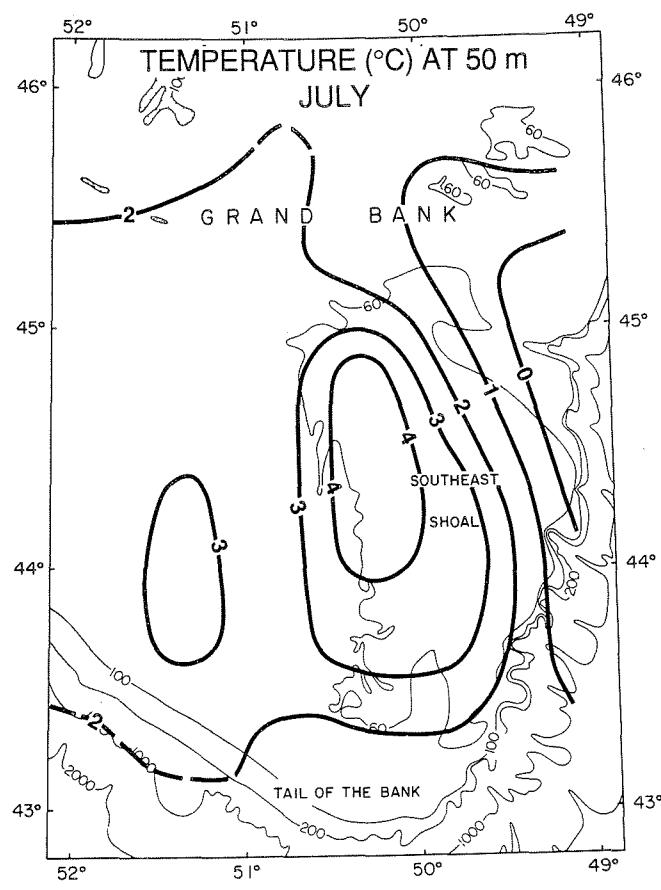

Figure 1. Climatological temperature distribution on the southern Grand Bank in July. Contours are based on the MEDS long-term monthly means for  $1/2 \times 1/2$  degree areas.

TABLE 1

Summary of mooring positions, depths and data return periods for all moored measurements made as part of the Southeast Shoal Exchange Study in 1986 and 1987. The instruments used were: Aanderaa current meters (CM), Aanderaa thermistor chains (TC), Hermes/ARGOS surface buoy (AR), and Ryan thermographs (RT). The periods of good data return for some parameters are less than those indicated for the instrument.

### Mooring Locations

The moorings for the Southeast Shoal experiments were laid out as shown in Table 1 and Figure 2. Each current meter mooring location was protected by a triangular array of surface guard buoys. Single guard buoys were used as the carrier for the Ryan thermographs.

### Instrumentation

**Current meters:** all current meters used were Aanderaa RCM5's fitted with paddle wheel rotors. The instruments recorded pressure (not presented in this data report) temperature, current speed, current direction and conductivity, i.e. salinity at 30-minute intervals. The manufacturer quotes accuracies for this instrument as: time within  $\pm 2$  s/d; temperature  $\pm 0.15^{\circ}\text{C}$  with a response time of 12 s; current speed  $\pm 1$  cm/s with a threshold of 1.5 cm/s; current direction  $\pm 5^{\circ}$  for speeds above 5 cm/s and tilt less than  $12^{\circ}$  from horizontal; and conductivity  $\pm 0.025$  mmho/cm. Each of the instruments had their compasses calibrated prior to deployment and CTD stations were occupied near the moorings to provide a check on temperature and give a calibration for salinity.

**Thermistor chains:** both thermistor chains were Aanderaa TR2 chains with a quoted accuracy of  $\pm 0.15^{\circ}\text{C}$  with a time response of 3.5 min.

**Thermographs:** Ryan Thermographs Model J were used to acquire additional temperature time series. These instruments record internally on a strip chart. The instruments are calibrated in-house and the data are accurate to  $\pm 0.5^{\circ}\text{C}$ .

**ARGOS buoys:** These data platforms are manufactured by Hermes Electronics and are a modification of the FGGE drifting buoys. They are equipped with a Paroscientific barometer and a temperature sensor inside the hull of the buoy. Data are relayed via satellite and the ARGOS data centre. The barometric pressure is believed to be accurate to  $\pm 1$  mbar and the temperature sensor is more accurate than a knowledge of exactly what it is measuring. During daytime periods the instrument is warmed above sea surface temperature and it is possible that cold air temperatures could

lower the buoy temperature below sea surface temperature.

**Geostrophic winds:** are computed by the Atmospheric Environment Service (pressures from FNOC) and presented for the grid point 44 06N, 50 30W which is taken to be representative of Southeast Shoal. The time series has a sampling interval of 6 hours.

#### Data Processing

**Current meters:** the data recorded by the Aanderaa instruments were translated to computer readable files. The direction data are corrected by applying the calibration data from the compass swing and also corrected for the local magnetic variation as given on navigational charts for the area. The current speed is computed by applying a linear relationship to the encoder value according to the data supplied by the manufacturer. The current velocity is determined by taking the direction as the arithmetic mean of the direction data at the beginning and end of the speed integration period. The average speed/direction is then time-stamped at the mid-point of the cycle. Temperature is computed by applying a cubic polynomial fitted to the in-house calibration. The pressure and conductivity use linear relationships. Salinity according to the Practical Salinity Scale of 1978 was computed using temperature, pressure and conductivity with no allowance made for time constant mis-matches. Adjustments indicated by CTD calibration stations were applied as an added constant. The density anomaly ( $\sigma_t$ ) refers to the anomaly of the 1980 Equation of State from 1000 kg/m<sup>3</sup>.

Time series of north (v) and east (u) components of velocity were computed. Editing involved range specification, median filtering, spike removal and manual inspection. There was serious data degradation due to encoder problems in most of the 1987 data. This is very noticeable in both records at mooring 831 and the shallow instrument on 832. Portions of some of the time series were deleted when it was felt that no useful information could be recovered. The deepest instruments at the central mooring site (45 m on mooring 774 and 44 m on 830) were subject to excessive

biological fouling. Tidal analysis on 5-day blocks of the current data was used to identify the onset of significant degradation of the speed sensor. Both these records were truncated on this basis.

**Thermistor chains:** a cubic polynomial was fitted to the manufacturer's calibration for the temperature sensors. Editing similar to that for the current meters was performed but the signals were much better and required little interference.

**Thermographs:** The strip chart records were translated, using a digitizing tablet, to 4-hourly values in computer readable format. Constant offsets determined from comparison with CTD and XBT profiles were applied as appropriate.

**ARGOS buoy:** these data were received from Service Argos for the 1986 records and until the end of August 1987. After that time the data were received from a 'local user terminal' operated by AES, Downsview. For this reason there are fewer data points and occasional data gaps after day 244 of 1987. The data received were used to recover an original time series of 6-hourly data. Because the satellite recovered data is not equi-spaced the data received was interpolated to an equi-spaced time series by linear interpolation from the data point before and after. Gaps greater than 24 h were not interpolated across.

#### Data Presentation

Each time series is treated in two modes; a) the original time series at its nominal sampling interval (30 min for current meters, 60 min for thermistor chains, 4 h for thermographs, 6 h for ARGOS buoy and geostrophic winds) and, b) a low pass filtered time series. The low pass filter is a Cartwright filter that passes more than 95% of the input power for periods longer than 40 h, 50% at 31 h and less than 1% for periods less than 24 h. All the resulting time series are subsampled every 6 h.

A table of statistics is given for each record. In this table are the number of points, mean, standard deviation of the original time series ( $\Sigma_1$ ) and the standard deviation of the low pass filtered

time series ( $\Sigma_2$ ). For the current meter records the density anomaly ( $\sigma_t$ ) is computed only for the low pass filtered time series. The same statistics are also given on a monthly basis for each month and each record having a significant number of points.

Time series plots are shown for each record, for the original and then the low pass filtered time series. Current meter data are also shown as progressive vector diagrams, using the unfiltered time series with symbols every 5 days and labelled with year day numbers every 20 days. A stick diagram of velocity vectors is plotted from the low pass filtered time series. A table of the major tidal constituents ( $K_1$ ,  $O_1$ ,  $M_2$ ,  $S_2$ ,  $N_2$ ,  $M_f$ ,  $M_4$ , and  $MS_4$ ) is given for each current record. These constituents are determined from the maximum possible length of record.

Spectra are presented for each time series in two forms: log-log presentation of spectral power against frequency and log-linear presentation of frequency times spectral power against frequency (i.e. energy preserving display). The spectra are computed by using a fast Fourier transform on blocks of data that have had their mean and trends removed, averaging over variable frequency space to give nearly logarithmic spacing and averaging the estimates from each block. The standard error associated with the block to block variability of each spectral estimate is used to give the error estimate shown on each spectral estimate.

Throughout, an attempt has been made to minimize the number of scales used for each presentation so that comparison from record to record may be made.

#### ACKNOWLEDGEMENTS

We would like to thank the many people who helped to collect and present these data; in particular the officers and crew of CSS DAWSON, the technical support within PCS for equipment preparation and operation, the computer systems personnel for writing the software and the data shop for using it, the illustrations section for preparation of some figures and R. Lively for assistance with some of his more esoteric data presentation programs.
