Canadian Manuscript Report of
Fisheries and Aquatic Sciences No. 3082

## Canadian Manuscript Report of Fisheries and Aquatic Sciences

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of Fisheries and Oceans Canada, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in the data base Aquatic Sciences and Fisheries Abstracts.

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page.

Numbers 1-900 in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551.

## Rapport manuscrit canadien des sciences halieutiques et aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui traitent de problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. II n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques de Pêches et Océans Canada, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications à part entière. Le titre exact figure au-dessus du résumé de chaque rapport. Les rapports manuscrits sont résumés dans la base de données Résumés des sciences aquatiques et halieutiques.

Les rapports manuscrits sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre.

Les numéros 1 à 900 de cette série ont été publiés à titre de Manuscrits (série biologique) de l'Office de biologie du Canada, et après le changement de la désignation de cet organisme par décret du Parlement, en 1937, ont été classés comme Manuscrits (série biologique) de l'Office des recherches sur les pêcheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de Rapports manuscrits de I'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de Rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

#### Abstract

Veinott, G. and Cochrane, N. 2015. Characteristics of the Newfoundland and Labrador Atlantic Salmon (Salmo salar) Recreational Fishery based on Angler Logs and Phone Surveys (1994-2013). Can. Manuscr. Rep. Fish. Aquat. Sci. 3082: vii + 51 p.

Anglers of Atlantic Salmon in Newfoundland and Labrador have been self-reporting catch and effort data since 1994 and have also been surveyed annually by phone since 1998. During that time very few significant trends in catch and effort have been observed. On average, anglers consistently catch approximately fourfish per year, two of which they harvest. However, the most commonly reported outcome for anglers with effort was zero catch. The exceptions were Labrador, where respondents with effort often reported a catch of greater than 6 fish, and the South Coast where retention has dropped to approximately 1 fish per angler per year. NL anglers are primarily retention anglers with less than $5 \%$ reporting the release of their entire catch. Resource managers wishing to reduce catch and harvest could reduce the season bag limit, and/or limit the number of licences available, which would reduce harvest by reducing total effort.

## RÉSUMÉ

Veinott, G. and Cochrane, N. 2015. Caractéristiques de la pêche récréative du saumon de l'Atlantique (Salmo salar) à Terre-Neuve-et-Labrador, fondées sur les registres des pêcheurs à la ligne et les renseignements obtenus par sondage téléphonique (de 1994 à 2013). Can. Manuscr. Rep. Fish. Aquat. Sci. 3082: vii +51 p.

Les pêcheurs à la ligne de saumon de l'Atlantique à Terre-Neuve-et-Labrador produisent des rapports volontaires sur les données relatives aux prises et à l'effort depuis 1994 et ils font également l'objet d'un sondage téléphonique annuel depuis 1998. Durant cette période, très peu de tendances importantes en matière de prises et d'effort ont été observées. En moyenne, les pêcheurs à la ligne capturent systématiquement environ quatre poissons par an, dont deux qu'ils récoltent. Cependant, le résultat déclaré le plus fréquemment pour les pêcheurs à la ligne ayant fourni un effort correspondait à une prise nulle. Le Labrador, où les répondants ayant fourni un effort ont souvent déclaré une prise de plus de six poissons, et la côte Sud, où la rétention a diminué pour atteindre environ un poisson par pêcheur par an, constituent des exceptions. Les pêcheurs de Terre-Neuve-et-Labrador sont principalement des pêcheurs conservant leurs prises puisque moins de $5 \%$ ont déclaré la remise à l'eau de la totalité de leurs prises. Les gestionnaires des ressources qui souhaitent réduire les prises et la récolte pourraient réduire la limite saisonnière de prises ou limiter le nombre de permis disponibles, ce qui réduirait la récolte en diminuant l'effort total.

## INTRODUCTION

In order to fish for Atlantic Salmon in Newfoundland and Labrador (NL), anglers are required to purchase an Atlantic Salmon angling licence. The licences are produced by the NL government and distributed to retailers throughout the province. Although anyone can obtain a salmon licence, the vast majority (90\%) of licence sales over the past 20 years have been to NL residents. For nonresidents and individuals under 14 years of age, special regulations exist that restrict where and with whom they can angle (DFO 2014). Starting in 1994 changes were made to the salmon licence, so that it would consist of two parts, a vendor's sales slip and an angler log or stub (both in duplicate) (O'Connell et al. 1998). The vendor's sales slip is used to record information identifying the angler (name, address, gender, and proof of residency) (Fig. 1 top), and is retained by the vendor. The angler stub or $\log$ (Fig. 1 bottom) is retained by the angler to keep a record of their fishing activities (catch, effort, rivers fished, etc.) throughout the fishing season. Vendors are expected to return one copy of the sales slip to the province and the other to the Department of Fisheries and Oceans (DFO). Anglers are asked to submit their angling data electronically through the DFO's web page or mail their log to the DFO at the end of the angling season regardless of whether they fished or not.

Twenty-thirteen marks the twentieth year that the Newfound and Labrador region of the DFO has been collecting data on the province's Atlantic Salmon anglers. During that time approximately 348,000 licences have been sold and information on over 170,000 anglers engaging in well over half a million angling trips has been collected. This report is a synthesis of those 20 years of data.

## METHODS

## TOTAL NUMBER OF LICENCES SOLD

When a salmon licence is sold in NL, the vendor sends a copy of that licence with the licence number, angler name, address, etc. to the DFO. This information is entered into a database and the total number of licences received by the DFO from the vendors is defined as the total number of licences sold.

## DEFINING RESPONDENTS AND NON-RESPONDENTS

Any angler that purchases a licence is expected to fill out the angler log attached to the licence and submit that data to the DFO either by mail or electronically through the DFO web page. Information from the angler log consists of the licence number, area and river fished, hours fished, catch of small salmon (< 63 cm ), catch of large salmon ( $\geq 63 \mathrm{~cm}$ ), and size and number of retained and released salmon. However, in any given year only a small proportion of anglers return their logs voluntarily. Therefore, three times a year, usually starting in midOctober, and ending in January of the next year, reminders are sent to any angler that has not voluntarily returned their log. An exception occurred in 2012 when owing to budgetary constraints only two reminders were mailed out. The
reminder consists of a postcard asking anglers to submit their angling information and a blank angling log for them to fill out in case the original was lost or destroyed. Any angler that submits their angling information either voluntarily or after being prompted are categorized as respondents. All other anglers are categorized as non-respondents.

## TELEPHONE SURVEY OF NON-RESPONDENTS

In 1998, the DFO began a telephone survey of non-respondents. The survey takes place in February or March and covers anglers that fished in the previous calendar year but did not submit their angling log. This provides a grace period for anglers to respond to reminders that were recently sent. After the grace period, 5000 names of non-respondents are selected, at random, and contact is attempted by telephone. Anglers that are contacted and agree to be interviewed are asked to recall the rivers fished, number of days fished, hours fished, and the numbers of small and large salmon caught, retained, and released. The survey continues for 3 weeks and has successfully interviewed an average of $15.6 \% \pm$ $4 \%$ of all non-respondents annually.

## DATA HANDLING AND ANALYSIS

Angling data from respondents and non-respondents are entered into an electronic database. Each reported angling event is entered on a separate line so that information such as the total number of angling events, daily catch, rivers fished, etc. can be extracted for each licence holder. Information from the vendors (angler name, address, age, etc.) is entered into a separate database so that angling data can be analyzed without access to the corresponding personal information.

The main metrics presented in this report are based on reported angler catch and effort. Trends in catch and effort, as well as the proportion of anglers catching zero, one, two, etc. fish were examined. However, only noteworthy trends are presented and discussed. Summaries of all data are provided in the appendices.

The examined trends in catch and effort etc. are presented based on geographic regions. First, trends in catch and effort, reported for the province and extrapolated to the entire angling population, are presented (method given below). Next the province is divided into insular Newfoundland and Labrador, and finally the province is divided into regions based on COSEWIC's (Committee on the Status of Endangered Wildlife in Canada) designatable units (DUs) (COSEWIC 2010), and the angling data is presented by DU (Fig. 2). This allowed for a comparison among different regions of the province.

## Catch and effort

Angling catch is divided into: retained catch, salmon that are legally retained or kept by the angler; released catch, salmon that are deliberately returned to the water alive after being caught; and total catch, the sum of the retained and
released catch. Angling catch is also categorized by the size of the fish (large and small salmon). However, it has been illegal to retain large salmon in the recreational fishery in insular NL since 1985 and in Labrador since 2011.

Effort is defined by rod days. A rod day is any day or part thereof that an angler spends fishing on a given river. For example, if an angler leaves River A and fishes a second river (River B) in the same day, then that would be recorded in the data base as two rod days: one rod day for River A and one rod day for River B. By 1997 it was observed that a substantial number of anglers appeared to be reporting effort only when catch occurred. Therefore, from 1997 to 1999 telephone surveys were carried out to ask anglers whether they had effort without catch and whether they reported that effort. Based on the results of those surveys it was determined that approximately $18 \%$ of effort was not being reported. Therefore all annual estimates of effort have been adjusted by $18 \%$ to reflect that unreported effort.

To analyze the reported catch and effort data, anglers (respondents and nonrespondents) were divided into those that purchased a licence but did not fish (null effort) and those with effort. Average catch per angler (retained, released or total) is simply the number of salmon caught divided by the number of anglers with effort. Average effort is the total number of rod days divided by the total number of anglers with effort. Catch per unit effort (CPUE) is catch divided by effort.

Although average catch is a statistic easily understood, recreational catch data often contain an excess of zero catches (O'Neill and Faddy 2003; Taylor et al. 2011). An excess of zero catches creates a skewed distribution in which the mean can still be used for comparison among years, but biases the mean as a measure of central tendency. Therefore, in some cases zero catch is examined separately.

## Extrapolating to entire angler population

The angling population in NL is grouped into respondents and non-respondents. From 1994 to 1997, prior to the initiation of the telephone survey, catch and effort data were extrapolated to the entire angling population based on the respondents' data alone (O'Neil et al. 1986; O'Neil et al. 1989; O'Connell et al. 1998). However, the initiation of the telephone surveys in 1998 provided a direct measure of fishing activity by non-respondents. Estimating catch and effort for the entire angling population could now be based on the respondents and nonrespondents data. Catch and effort for all non-respondents is estimated by first calculating the average catch and effort of the non-respondents contacted in the telephone survey, then multiplying the average by the total number of nonrespondents with effort. Catch and effort for the entire angling population is the sum of the reported respondents catch and effort plus the extrapolated nonrespondents catch and effort (Veinott and Cochrane 2014). In 2001, it was
decided to re-calculate non-respondents' catch and effort for 1994 to 1997 based on average catch and effort from the first three years of the non-respondents' phone survey (1998-2000).

## RESULTS

## ANGLING DATA FOR THE PROVINCE

The total number of salmon angling licences sold in NL peaked in 1997 at over 25,000 then declined to a series low in 2007 (Fig. 3). Since 2007, licence sales have been increasing with over 22,000 sold in 2013. Unfortunately the number of respondents returning their angler logs has not followed the same trend. Numbers and the proportion of anglers returning their logs declined sharply between 1996 and 1998 then stabilized somewhat, but has since reached a series low in 2013 of just 17\% (Fig. 4).

Catch (total, retained, and released) extrapolated to the whole angling population is shown in Figure 5. Total catch averaged just over 57,000 fish and the annual trend mirrored, to some extent, the trend in licence sales. This is most likely owing to increased effort in years of high licence sales as catch and effort are highly correlated (Fig. 6). Retained catch (harvest) averaged 45\% of the total catch through the time series (Fig. 5).

Average annual total catch per angler (Fig. 7A) has varied very little throughout the time series and has ranged between 3 and 5 fish. Average harvest has not changed much over the time series either. Respondents have been consistently reporting an average harvest of between 1.5 and 2 fish annually, while nonrespondents harvest an average of 1.5 fish per year (Fig. 7B). One trend worth noting is in the catch of large salmon. The average number of large fish retained by respondents and non-respondents has been reduced to zero in recent years because of a regulation change, while the average number of large fish released by respondents has been increasing (Fig. 7C). Respondents reported releasing, on average, nearly twice as many large fish in 2013 compared to 1994 (Fig. 7C). Effort and CPUE showed very little change over the last 20 years (Fig. 8A-B). However, non-respondents consistently reported more effort and generally less catch compared to respondents. The increased effort with lower average catches reported by non-respondents resulted in a lower average CPUE for nonrespondents relative to respondents (Fig. 8B). One statistic that appears to be increasing is the number of anglers that bought a licence but reported that they did not fish (null effort) (Fig. 9). In recent years (2011-2013) over one-quarter of respondents reported that they did not fish. During the same time over $20 \%$ of the non-respondents also stated that they bought a licence but did not fish.

## ANGLING DATA BY REGION

To examine and compare trends in catch and effort within NL, the province was divided into regions. First, Labrador and Insular Newfoundland data were
separated; then insular Newfoundland was further divided into the Northeast Coast, South Coast, Southwest Coast, and Northwest Coast. Labrador and the four island divisions overlap with COSEWIC's designatable units and as such are assumed to represent geographically and/or biologically distinct groupings of salmon populations (COSEWIC 2010). Unlike the results for the province which took the reported respondents and non-respondents data and extrapolated them to the entire angling population, the regional trends use reported catch and effort only without extrapolating to the angling population for that region. This was done because of the high variability in angler populations among regions. To account for differences in the number of angler reports between regions; averages and percentages were calculated and presented rather than absolute abundances. As well, comparisons are only made among regions and not between the regions and the province because anglers can fish in multiple regions in any given year.

## Labrador

The angling data for Labrador combined angler reports from salmon fishing areas (SFA's) 1, 2 and 14B which is equivalent to COSEWIC's DU 2 (Fig. 2) (COSEWIC 2010). Average total catch by respondents reached a series high in 2013 with respondents reporting catches of over 9 fish per angler (Fig. 10A). Average total catch reported by non-respondents was generally lower that that reported by respondents, but there has been a general upward trend in catch since 2001. In contrast to the increasing total catch reported by both groups, total harvest (large + small salmon retained) declined in the early part of the series and has averaged just over 1 fish per angler in the non-respondents category and approximately 1.5 fish per angler in the respondents category since 2001(Fig. 10B). Effort (Fig. 10C) has remained remarkably consistent for respondents throughout the time series, averaging slightly less than 5 rod days per angler annually. As with the provincial data, non-respondents fishing in Labrador consistently reported greater effort while catching less fish compared to respondents resulting in a lower CPUE for non-respondents (Fig. 10D).

The proportion of respondents reporting a total catch of greater than 6 fish in Labrador has been steadily increasing and reached a series high in 2013 at just over $46 \%$ (Fig. 11A). At the same time the number of respondents with effort reporting zero catch declined to about 11\% in 2013 (Fig. 11A). These trends are correlated with the number of fish being released in Labrador as more respondents reported releasing more than 6 fish and fewer respondents reported releasing no fish (Fig. 11B). This resulted in the increase in CPUE observed for respondents in Figure 10D. Similar trends were not observed in the nonrespondents data as average catch was more variable and the proportion of nonrespondents reporting catches greater than 6 fish or zero fish were about equal ( $25 \%$ ) (Fig.11C). There was an increase in the percentage of non-respondents reporting fishing 3 to 5 days annually ( $\sim 40 \%$ ), while the proportion fishing greater than 10 days annually, decreased slightly to less than 10\% (Fig. 12).

## Insular Newfoundland

The island of Newfoundland is made up of 12 SFA's and by virtue of the population produces a high proportion of the collected angling data. Therefore, there is very little difference between, for example, the trends in average total catch or average harvest for the island (Fig. 13) compared to the province (Fig. 7A, B). Similarly trends in effort and by default CPUE are nearly identical for the island compared to the province (Compare Fig. 14 to Fig. 8). However, there are interesting differences between the island and Labrador. In Labrador, a high proportion of respondents ( $>30 \%$ in recent years) reported catching more than 6 fish in a season (Fig. 11). On the island the most common outcome for respondents is a catch of zero fish (Fig. 15A-B). The reporting of zero catch is even more pronounced in the non-respondents with greater than $30 \%$ of anglers who fished, reporting no catch annually (Fig. 15B).

Related to no catch is the percentage of anglers that report releasing no fish (Fig. 16). Roughly $60 \%$ to $70 \%$ of respondents and $70 \%$ to $80 \%$ of non-respondents report releasing no fish. These numbers include anglers that had no catch, or caught only large fish where release is mandatory, but it also reflects a penchant for Newfoundland anglers to retain their catch. For example, in 2013 there were 1913 respondents that reported catching at least one small fish. Of those only 83 reported retaining no small fish. Therefore, less than 5\% of respondents in 2013 voluntarily released all their small catch. The figure was lower for nonrespondents where less than $2.5 \%$ released their entire catch of small fish.

For respondents with retained catch there was a sharp increase between 1997 and 1998 in the number of anglers reporting retention of 4 fish (Fig. 17). Between those years the percentage of respondents reporting retention of 4 fish increased from less than 5 to over 15 and has remained at that $15 \%$ level since. During the same time the percentage of respondents retaining 3 salmon declined by an equivalent amount. The change in retention was likely driven by changes in the season bag limits, which went from 6 to 4 in 1998, or because of in-season reviews that limited catch for part of the season. In 1999, the River Classification System (Veinott et al. 2013) came into effect, which changed the allowed retention on a river-by-river basis and re-introduced a season bag limit of six salmon. As well, the River Classification System reduced the number of rivers where four salmon could be retained and increased the number where only two salmon could be retained. There were no rivers with a season bag limit of exactly three salmon. This likely explains the decline in the percentage of anglers retaining three salmon and the maintenance of the percentage of anglers reporting a retained catch of four salmon.

## Northeast Coast

In this report the Northeast Coast is defined as the area covered by DU3 (SFA's 3 to 8) (Fig. 2). Similar to the comparison between the island and the province,
the Northeast coast drives most of the trends for the island. Two of the largest salmon producing rives, Exploits River and Gander River, are located on the Northeast Coast thus producing a large proportion of the angling activity and angler reports for the island. Similar to the island as a whole, respondents on the Northeast Coast harvested approximately 1.7 small salmon per angler per year, while non-respondents averaged slightly less than 1.5 salmon per angler per year. However, there appears to be an increasing trend in average total catch and harvest especially in the respondents' category (Fig. 18A-B). Effort reported by respondents has remained constant averaging 5 days per angler per year, while effort by non-respondents showed a slightly declining trend (Fig. 19A). The stability or slight decline in effort coupled with increasing catch and harvest has resulted in an increase in CPUE for respondents in this region (Fig. 19B).

Unlike the island, the proportion of respondents reporting zero catch on the Northeast Coast appears to be steadily declining throughout the time series and is currently at $26 \%$ (Fig. 20A). A similar trend appears in the retained catch data where the number of respondents reporting zero harvest reached a series low of $22 \%$ in 2011(Fig. 20B). Catch of large fish is trending up as over 6\% of anglers reported catching one large salmon in 2013 compared to less than 4\% in 1994 (Fig. 20C).

In the non-respondents category, the number of anglers fishing more than 10 days per year has been in decline. It reached a series low of just under $14 \%$ in 2012 compared to a series high of $33.6 \%$ in 1995 (Fig. 21).

## South Coast

The South Coast of the island is made up of SFA's 9 through 12 and overlaps with COSEWIC's DU4. The salmon population of this DU has been designated as Threatened by COSEWIC (COSEWIC 2010). Nevertheless at the time of writing angling was still permitted on the South Coast.

Unlike other regions of the province examined so far average, harvest on the South Coast has been declining for respondents and non-respondents (Fig. 22A). Respondents harvested on average one fish per angler per year in 2013 compared to a peak of 1.7 fish per year in 1995. However, the average number of small salmon being released by respondents had been increasing until 2011 (Fig. 22B). Average effort declined slightly in both categories (Fig. 23A) over the time series resulting in little change in CPUE (Fig. 23B) despite continued declining abundance in the main index river (Conne River) for the South Coast (Robertson et al. 2013).

A catch of zero fish is still the most commonly reported outcome for anglers on the South Coast. Over 30\% of respondents and over 50\% of non-respondents with effort on the South Coast reported that they caught no fish in 2013 (Fig. 24). Retention is still an important component of the data as $60 \%$ or more of
respondents and 70\% or more of non-respondents consistently reported releasing no fish (Fig. 25). There was a large increase in 1999 in the proportion of respondents that reported retaining 2 fish (Fig 26). This corresponded to a drop in the percentage retaining 3 fish and is most likely a result of the implementation of the River Classification System (Veinott et al. 2013), which reduced the season bag limit on many South Coast rivers to 2 fish.

## Southwest Coast

The Southwest Coast is made up of a single SFA (13) (Fig. 2) and is its own COSEWIC DU (DU5) (COSEWIC 2010). This is because the salmon populations in the Southwest Coast rivers have a multi-sea-winter salmon stock component not observed anywhere else on the island. Multi-sea-winter salmon generally return to their home rivers to spawn for the first time as large salmon ( $>63 \mathrm{~cm}$ ).

The trends in catch and effort on the Southwest Coast tend to be in alignment with the other regions. The exception is in the statistics on large catch. Both respondents and non-respondents averaged greater catch of large salmon on the Southwest Coast compared to the other insular regions (Fig. 27A-B). Over the time series, respondents reported releasing an average of 0.67 large salmon per angler per year and non-respondents reported an average catch of 0.53 large salmon per year. Labrador excepted, the next closest region was the Northwest Coast (discussed below) with an average release of 0.30 large salmon per angler per year. Labrador, however, with respondents reporting an average catch of over one large salmon annually, was the region with the greatest reported catch of large salmon per angler.

## Northwest Coast

The Northwest coast is comprised of a single SFA (14A) and corresponds to COSEWIC's DU6. The separate COSEWIC designation was based on geography, geology and the smolt migration route northward through the Strait of Belle Isle (COSEWIC 2010).

There was little of note within the catch and effort statistics from the Northwest Coast. Anglers fishing rivers in SFA 14A reported catch and effort very similar with the remainder of the island. One exception is average total catch, which reached a series low in 2013 for respondents and non-respondents of 2.5 and 1.4 fish per angler, respectively (Fig. 28). However, anecdotal reports for 2014 suggest a better than average fishing season on the Northwest Coast so 2013 may be an anomaly. As in other parts of the province, the most commonly reported outcome of a fishing trip was zero catch, however, for those with catch retention rates were high.

## DISCUSSION

Self-reported angling data should always be viewed with some caution as biases are inherent in such programs (Pollock et al. 1994). Often respondents consist of the more avid angler (Dorow and Arlinghaus 2011) and catch statistics and biological characteristics (lengths and weights) can be exaggerated (Essig and Holliday 1991). Low response rates can also cause problems as the question of a representative sample becomes a concern. Despite the potential problems with an angler diary or log program, many have reported successful outcomes from such programs. Kerr (2007), based on angler diary programs in Ontario, concluded that muskellunge (Esox masquinongy) catch rates had improved and attributed the improvement to new minimum size limit regulations and increased catch-and-release practices. Long-term changes in pike (Esox Lucius) populations were revealed through voluntary angler log books (Jansen et al. 2013) and trends in steelhead (Oncorhynchus mykiss) abundance from an angler questionnaire were validated by fisheries independent data (Smith et al. 2000). In their study of angler diary programs in Ontario, Cooke et al. (2000) found that frequent contact with participants through some sort of a reminder, similar to whatwas used in this report, was a characteristic of successful angler diary programs.

If we assume that the trends observed in catch and CPUE in this study are an accurate reflection of the NL angler's experience, then for anglers on the island there has been very little change over the last 20 years. Average catch per angler per year has changed very little and CPUE has remained stable. There were some regional improvements. There was a slight increase in average catch with less effort for anglers on the Northeast Coast, and Labrador saw a steady increase in total average catch of respondents over the 20 years. Improved catch on the Northeast Coast can probably be attributed to the increase in returns observed on Exploits River (Bourgeois et al. 2012). Although not part of this study, catch and abundance on the Exploits River are highly correlated (unpublished data this office). The increase in catch for Labrador respondents may be related to increased abundance as Labrador rivers have shown a steady increase in returns since the early 1990's (ICES 2014). Another possibility for Labrador is that respondents from Labrador may be more avid, specialized anglers. Labrador is isolated and requires considerable commitment and expense to angle there recreationally. Respondents are often the more avid anglers (Dorow and Arlinghaus 2011; Bray and Schramm 2001), and Beardmore et al. (2011) found that specialized or committed anglers were more catchoriented. If respondents in Labrador are motivated by catch, then their angling experience has been improving.

A difference in catch and effort between respondents and non-respondents was not unexpected as many studies have shown non-response bias in angling surveys (Fisher 1996; Connelly and Brown 1995; Connelly et al. 2000). However, in our study non-respondents were surveyed directly so there was no need to adjust the respondents' data to account for non-response. Veinott and Cochrane
(2014) showed that given the number of non-respondents sampled each year in the NL licence stub program, the margin of error on the catch and effort statistics should be less than $5 \%$ suggesting that the survey is providing an accurate estimate of the non-respondents' memory of their catch and effort. Unfortunately re-call bias has never been studied in this population. Regardless, if the nonresponse data is believed, then there is a clear difference in catch and effort between the respondents and non-respondents. The most striking difference is in effort. Provincially non-respondents have consistently reported 1.5 to 2 times more effort compared to respondents. Combined with less fish caught, nonrespondents have consistently lower CPUE, and this is observed across all regions of the province. Is the lower CPUE because non-respondents are less skilled anglers requiring more effort to catch their bag limits? If so, that supports the studies that concluded respondents were the more avid and presumably more skilled anglers (Dorow and Arlinghaus 2011; Bray and Schramm 2001). Intuitively one might expect the more avid angler to fish more often (greater effort), but if the angler is harvest oriented as suggested by the small percentage of NL anglers that release their entire catch, then the more skilled anglers may fill their bag limit with less effort.

Catch and effort are highly correlated in NL which shows that if regulators want to reduce catch, one way to achieve that outcome would be to reduce effort. Effort can increase either by individual anglers fishing more often or increased participation by the general public. Given that average effort for respondents and non-respondents has changed very little over the time series and across regions, attempting to regulate the number of days individual anglers could fish would seem unnecessarily difficult. However, it would be very simple to restrict the number of new entrants to the fishery by limiting the number of available licences. This is common for big game. Another option to reduce catch and harvest is to reduce the bag limits. The last major regulation change in the NL salmon fishery was the introduction of the River Classification System in 1999. This program introduced seasonal and daily bag limits on a river-by-river basis effectively reducing the season bag limit to 2 fish on the majority of scheduled salmon rivers within the province. Veinott et al. (2013) concluded that the River Classification System had no effect on effort but reduced overall harvest, and shifted harvest to the rivers with higher allowed retention. This is similar to that reported by Johnston et al. (2011) who speculated that harvest-oriented anglers abandoned a recreational bull trout (Salvelinus confluentus) fishery after the implementation of a total catch-and-release regulation despite improved catch rates. Since Veinott et al. (2013) and these data both suggest that anglers in NL are harvest-oriented it is no surprise that the average annual harvest has been approximately 2 fish per angler per year over the time series. It seems likely harvest in NL would adjust to whatever the set bag limit is.

## CONCLUSIONS

There were very few significant trends observed in catch and effort over the 20 year time series of the angler log program. Anglers consistently averaged a catch of approximately 4 fish per year and harvested approximately 2 each. However, the most commonly reported outcome for anglers with effort was zero catch. The exception was Labrador, where respondents with effort often reported a catch of more than 6 fish, and the South Coast where retention has dropped to approximately 1 fish per angler per year. NL anglers are primarily retention anglers with less than $5 \%$ reporting the release of their entire catch. Resource managers wishing to reduce catch and harvest could reduce the season bag limit, or reduce the number of available licences, which would reduce harvest by reducing effort.
