ISE OF ELECTRIC POWER
IN
MANIFACTURTNG AND MINING INDUSTRIES IN CANADA

1934

This roport, issued during the past five years, has attempted to show the evolution of power machinery in manufacturing and mining industries in Canada toward electric drive and particularly toward electric motors driven by power generated in central stations. With no coal mined in the chief mamfacturing provinces of Ontario and quebec and with a large supply of water power within economic transmission distance of manufacturing and mining contres in these and in most of the other provinces, this trend has been more pronounced than in many countries. The trend has been measured by the ratio of electric motor capacity to total power equipment installed in these industries, the central eloctric station industry being excluded as one of the manufacturing industries.

The report for the first four years also contained data on the production of electric power as reported monthly, but these data are now published monthly in a separate report.

This ratio of olectric motor rating to total power equipment indicates this avolution, but the movement towards electric drime is slightly exaggerated because of the practice in mills, factorles, etc. of instailing motors at each machine or group of machines with a total capaçty greater than would be necassary if only one large motor were used or if a stam angine and belts and shafting were used. In the early annual industrial censuses no segregation was made of elewtric motors operated on power purchased from contral eloctric stations and on power produced within the establishment making the report Consequently, 1923 is the first year for which total power emplayed can be compiled without duplication.

During the eleven years betwann 1923 and 1934 there has been very little net increase in the use of water power in manufacturing industries outside of the central electric station industry which is axcluded here. Stean engines increased by 40.7 per cent and internal combustion engines increased by 86.1 per cent, but the use of this latter type is still a very small part of the total. Elactric motors operated on contral station power, howaver, fincreased by 190.0 per cent and all electric motors increased by 153.1 per cent in capacity. The details are as follows:

POWER EQUIPMENT IN MANUFACTURING INDUSTRIES

|  | C a pacity |  | Per cent of Increase |
| :---: | :---: | :---: | :---: |
|  | 1923 | 1934 |  |
|  | H.P. | H.P. |  |
| Water wheels | 587,191 | 597,687 | 1.8 |
| Steam engines | 554,191 | 779,949 | 40.7 |
| Internal combustion (gas \& oil) engines | 46,829 | 87,147 | 86.1 |
| Total | 1,188,211 | 1,464,783 | 23.3 |
| Electric motors on purchased power ............. | 958,692 | 2,779,913 | 190.1 |
| Total Power ................................ | 2,146,903 | 4,244,696 | 97.7 |
| Electric motors on power produced in the industries | 357,136 | 550,500 | 54.1 |
| Total Electric Motors | 1,315,828 | 3,330,413 | 153.1 |

The ratio of electric motor capacity to total power employed has increased steadily from 1923 with only two small recessions and for 1934 was 78.5 per cent. Many industries use electric drive exclusively and scores of others have ratios above 90 per cent. This rise from 61.3 per cent in 1923 to 78.5 per cent in 1934 was affected largely by the pulp and paper mills included in Group 4, "Wood and Paper Products." The ratio of this group increased from 50 per cent in 1923 to 72 per cent in 1934 and the electric motors increased in total capacity from 569,437 horse power to $1,529,058$ horse power. This accounted for close to 48 per cent of the total electric motor increase in all manufacturing industries. Non-ferrous metal products also showed a large increase from 47 per cent to 94 per cent during this period. The electric motors in this group had a capacity of only 381,150 horse power in 1934, or 11.4 per cent of the total in all manufacturing industries and, consequently, the effect on the total was small. Increases in other groups ranged from one to eleven points with two groups showing slight decreases. These comparisons are shown in Table 3.

Data in Table 4 are for all manufacturing industries, by groups, but data for only the large power industries in each group are shown separately. The table shows for the first tine the kilowatt hour consumption and because a few industries had large consurapions, ilthough relatively small power equipinent installations, these have been inchined also. The large kilowatt hour consumption in these was largely in electric ovens, electric furnaces, electro-chemical processes, etc., and not solely for lighting and driving machines.

The mining industries in Canada are nearly as completely electrified as the * $\quad$ cturing industries witi the exception of the fuel group and the increase in the re io of electric inotors to total power equipment during these eleven years has been evag greater, rising from 57.3 per cent in 1923 to 75.1 per cent in 1934. Data for the mining industries are shown in Tables 2 and 6.

Tables 7,8 and 9 show for the nine groups of manufacturing industries and the totsic, (1) tice horse power ratings of the power equipment, (2) the number of employees, $\therefore 2:(\%)$ he net value of production for the years 1923-1934, and the index numbers of fitece tre insed on pages 14-17.

While the power equipment in all manufacturing industries almost doubled in capacity between 1923 and 1934, the net value of production rose to a peak in 1929 and then declined rapidly to 1932 and rose again in 1934. The two curves pere approximately parallel from 1924 to 1929, but with the decline in business the net value of production naturally fell off while the equipment retained its position, although probably some of it was idle, and it also showed small net increases each year throughout the depression. The employees also increased in number from 1924 to 1929, but at a much lower rate than the power and net value of production and declined in somewhat the same way as the net value of production in 1930-1933 and rose in 1934. The peak reached by the employee curve in 1929 was only 32 points above the 1923 level, whereas the power curve rose 80 points and by 1934 had reached 97.7 points above the 1923 level.

These curves show the steadily increasing spread between power and employees employed in manufacturing industries. The charts for some of the nine groups show much greater spreads than the curves for the totals and quite probably curves for individual industries would show even greater differences.

A change in method of computing the number of employees for the years 1925-1930, inclusive, tended to increase the number for these years so that the peaks in 1929 are higher than if this change had not been made and the divergence from the power curves is consequently less. For the years 1923 and 1924 and again 1931 onwards the number of employees was computed by dividing the sum of the monthly counts by 12. Thus it represented the average man year positions. For the years 1925-1930, inclusive, the sum of the monthly counts for each plant was divided by the number of months the plant operated which would give the average monthly employment. This second method produced a much higher figure for seasonal industries, such as fruit, vegetable and fish canneries, and was probably an important factor in raising the employee clurve above the power curve for Group 1, "Vegetable Products," and for the sharp rise in 1925 for Group 2, "Animal Products," and some of the other groups. The change in method of computing employees would only cause breaks in the curves upward in 1925 and downward in 1931 and would not affect the slopes of the curves except at these points. It is impossible, however, to calculate the exact effect of the change.

The three sets of data for these tebles (7-8-9) and graphs were compiled from the same reports and consequently the curves indicate change in manufacturing technique, largely a substitution of mechanical power for man power.

The non-ferrous metal products industries showed an increase in power of 250 per cent from 1923 to 1929 and another 100 per cent to 1934 , whereas the number of employees increased by only 86 per cent to 1929 and then declinad to 1933. This group showed only 47 per cent electric drive in 1923 and 94 per cent in 1934. It is quite probable that this large increase in electric motors was a factor in this enormous spread betveen the power and employee curves. As stated above, over-installation is a characteristic of electric drive where individual motors are installed for each machine or groups of machines, but allowing half of the increase in electric motors in this group as excess capacity reduces the increase in power to 132 per cent between 1923 and 1929 for an increase in employees of only 86 per cent, 28 points of which were made in 1925 when the change in method of computation was made. This feature of electric drive probably affected the power curve of the "Wood and Paper Products" group which showed an increase in the ratio of electric motors to total power from 50 per cent in 1923 to 62 per cent in 1923 and to 72 per cent in 1934. The same adjustment for excess power in this group produced an increase in power between 1923 and 1929 of 46 per cent for an increase in employees of only 28 per cent. The increase in electric motor ratio to total power in the other groups did not exceed 11 points and, consequently, any excess motor capacity installed in these groups would have little effect on the spread between the power and employee curves.

It is not contended that the foregoing adjustment for excess motor capacity installed during these years is correct, but it is liberal. Even with it, a large difference existed between the rate at which the rated capacity of power equipment was being increased during the boom years up to 1929 and the rate at which the number of employees was being increased.

It is quite probable that, with a revival of business, the employee curve will rise at a sharpar angle than the power curve, 28 it did for all the groups in 1934, until the present power equipment is used to a higher per cent of its capacity than in 1934. It is also proba ble that, after that point is reached, the record of 1923-1929 will be continued and the capacity of power equipment will increase at a faster rate than employees.

Table 1. POWER EQUIPMENT OF ALL MANUFACTURING INDUSTRIES

## IN CANADA
