CENSUS AND ESTIMATED POPULATIONS OF CANADA AND THE PROVINCES

by SEX and AGE GROUP

1931 - 1945

---

I N T R O D U C T I O N

The present publication provides estimates of the population of Canada and the Provinces by sex and age for the years 1931-45. Estimates of the provincial populations have not previously been published.

The method of arriving at these estimates was briefly described in the Canada Year Book 1945, pages 129 ff, and is as follows:

The figures for 1931 and 1941 are those obtained from the Census. The estimates for the inter-censal years are calculated from the Censuses, the births and deaths of each year, known immigration to and emigration from the country, and certain cross classification available from the 1941 Census on inter-provincial migrants.

For Canada (exclusive of the Territories) the population of the 1931 Census was the starting point in the calculation. The Census figures by sex and single years of age were used up to age 25, and graduated figures (preserving 5-year totals) from age 25 on. The decision to use graduated figures was made after a study of the concentrations on even ages; it was observed that these concentrations are greatest at middle and older ages. The sharp fluctuations in the numbers at younger ages are to be attributed mainly to the great variations in the number of births during and after the first World War, and should not be smoothed out.

The Census is taken at the beginning of June. A "Census Year" may therefore be said to run from June 1st to May 31st. In order to obtain the number living at age 0 on June 1st of each year (i.e., the number of children less than 1 year of age), from the number of children born during each "Census Year" was subtracted the number of them who had died during the same period. At each other single year of age, the deaths occurring at that age were subtracted from the Census figures to give a first approximation to the number at the next higher age in the following year. This process was carried through successive years to 1941, and together with known immigrants and emigrants gave what might be called the "expected" figures of population for that

year. These expected figures were then compared with the actual figures obtained from the 1941 Census, and the differences at each year of age noted. The sum of these differences amounted to about 90,000 persons in all, and are in part attributable to migration out of the country on which data are not available.

The inter-censal estimates arrived at by the method described above were revised in the light of the differences found in 1941. The official revised estimates of the total population were compared with the totals of both sexes and all ages of the original estimates. The differences of each year were distributed between the two sexes and the different ages in the same ratio as the differences between the actual and expected figures were found to be distributed in 1941.

The estimates for the years following 1941 are being made from year to year by the same method as that used in the original estimates for the inter-censal years prior to 1941. The figures for 1942-45 will be revised following the 1951 Census; those for the years 1932-40 are now final.

For each Province taken separately essentially the same method was used as for Canada. A graduated population, preserving the totals of the 5-year age-groups, was obtained for 1931 as the starting point of the calculations. Each year births were added and deaths by single years of age were subtracted in order to arrive at the "expected populations" for each successive year in 1932-41. The "expected population" for 1941 was then compared with the actual 1941 population as obtained from the Census, and the differences by sex and age noted. These differences provided a pattern by which to distribute similar differences found in the original inter-censal estimates. As a final step, an adjustment had to be made to the populations of each Province so calculated by age and sex, in order that the totals of the provincial estimates in each sex and age group might add to the figures for Canada previously estimated. These latter figures may be considered more accurate, since the net migration to and from the country as a whole was a smaller factor than that between the Provinces.

Following the procedure of the estimates for Canada, the provincial estimates for the years 1942-45 were made by the same method as that used in the original estimates for the years prior to 1941. The ration card counts provided information for estimating interprovincial movement. The figures for 1942-45 will be revised following the 1951 Census. The figures for 1932-40, however, are now final.

POPULATION DE RECENSEMENT ET POPULATION ESTIMATIVE DU CANADA ET DES PROVINCES,

selon le SEXE et le GROUPE d'AGE

1931 - 1945

---

I N T R O D U C T I O N

La présente publication donne les estimations de la population du Canada et des provinces par sexe et par âge pour les années 1931-45. Les estimations de la population des provinces n'ont pas été publiées précédemment.

La méthode utilisée pour calculer ces estimations est brièvement décrite dans l'Annuaire du Canada, 1945, aux pages 129 et suivantes, comme suit:

Les chiffres de 1931 et de 1941 sont les chiffres mêmes du recensement. Les estimations des années entre recensements sont calculées d'après les recensements, les naissances et les décès de chaque année, l'immigration et l'émigration, et certaines classifications recoupées obtenues du recensement de 1941 sur le mouvement migratoire interprovincial.

Le point de départ du calcul pour le Canada (à exclusion des Territoires) fut le recensement de 1931. Les chiffres du recensement par sexe et par chaque année d'âge ont servi jusqu'à l'âge de 25 ans, et des chiffres gradués (conservant les totaux quinquennaux) de 25 ans en montant. Il a été décidé d'employer des chiffres gradués à la suite d'une étude des concentrations aux âges ronds; il a été constaté que ces concentrations sont plus marquées aux âges moyens et aux âges avancés. Les fluctuations violentes des chiffres de population aux âges moins avancés doivent être attribuées principalement aux grandes variations survenues dans le nombre des naissances durant et après la guerre de 1914-18; ces variations ne doivent pas être ajustées.

Le recensement a lieu au commencement de juin. On peut donc considérer une "année de recensement" comme allant du 1er juin au 31 mai. Afin d'obtenir le nombre de personnes vivant à l'âge 0 le 1er juin de chaque année (i.e. le nombre d'enfants de moins de 1 an), il a été soustrait du nombre des naissances durant chaque "année de recensement" le nombre de ceux-ci qui sont mort avant leur premier anniversaire. A chaque autre année d'âge, les décès survenus à cet âge ont été soustraits des chiffres du recensement pour donner une première approximation au chiffre de population à l'âge suivant pour l'année suivante. Cette méthode a été appliquée aux années successives de

1931 jusqu'à 1941 et, avec l'immigration et l'émigration connues, a donné ce qu'on pourrait désigner les chiffres "prévus" de la population en 1941. Ces chiffres prévus ont été ensuite comparés aux chiffres réels obtenus du recensement de 1941, et les différences à chaque année d'âge ainsi constatées. Ces différences s'élèvent au total de 90.000 personnes environ; elles sont attribuables en partie à l'émigration dont les chiffres ne sont pas connus.

Les estimations pour les années entre les recensements obtenues par la méthode décrite ci-dessus ont été révisées à la lumière des différences constatées en 1941. D'abord, des estimations révisées de la population totale ont été établies. Ensuite, ces estimations révisées ont été comparées aux totaux des deux sexes et de tous les âges des estimations originales. Les différences de chaque année ont été réparties entre les deux sexes et les différents âges dans la même proportion que les différences entre les chiffres réels et les chiffres prévus se trouvaient réparties en 1941.

Les estimations des années après 1941 se font d'année en année d'après la même méthode que les estimations originales des années 1932 à 1941. Les chiffres de 1942-45 seront révisés après le recensement de 1951; les chiffres des années 1932-40 sont maintenant définitifs.

Pour chaque province individuelle, la méthode utilisée est essentiellement la même. Une population à chiffres gradués, conservant les totaux des groupes d'âge quinquennaux, a été obtenue pour 1931 comme point de départ des calculs. Chaque année les naissances ont été ajoutées et les décès à chaque âge ont été soustraits afin d'obtenir les chiffres prévus de population pour chaque année successive de 1932 à 1941. Les chiffres prévus de la population en 1941 ont été ensuite comparés aux chiffres réels de 1941 tels qu'obtenus du recensement et les différences par sexe et par âge ont été constatées. Ces différences ont fourni un modèle d'après lequel les différences semblables constatées dans les estimations originales des années entre les recensements ont été réparties. Enfin, il a fallu ajuster la population de chaque province ainsi calculée par sexe et par âge afin que la somme des estimations provinciales pour chaque sexe et groupe d'âge corresponde aux chiffres du Canada déjà estimés. Ces derniers chiffres peuvent être considérés comme plus exacts que les chiffres provinciaux, vu que la migration nette dans le pays ou au dehors du pays était proportionnellement plus petit que la migration entre les provinces.

Tout comme pour les estimations du Canada, les estimations provinciales des années 1942-45 ont été faites d'après la même méthode que les estimations originales des années antérieures à 1941. Le comptage des cartes de rationnement a été une source de renseignements pour l'estimation du mouvement migratoire interprovincial. Les chiffres de 1942-45 seront révisés après le recensement de 1951. Les chiffres de 1932-40, cependant, sont maintenant définitifs.
