ACKNOWLEDGEMENTS

This is one of the four reports prepared for each designated group of the Employment Equity Program by the *Population Projections Section, Demography Division, Statistics Canada* under the direction of M.V. George, Chief, Population Projections Section, and R. Verma, Senior Analyst, Population Projections Section; Benoît Laroche, Director, Demography Division, supported and encouraged the work of this project. The other reports are on persons with disabilities at work; aboriginal population; and visible minorities.

The projection team provided the various inputs and technical assistance for this work as follows: the inputs for mortality projections were provided by François Nault and Réal Lortie; fertility projections by Ravi Verma, David Ford, and Shirley Loh; immigration projection by M.V. George and Ravi Verma, in consultation with Meyer Burstein of the former Employment and Immigration Canada; emigration projections by S. Rémillard; interprovincial migration projections by Alain Bélanger, Tim J. Werschler, M.V. George, Mary Jane Norris, François Nault, and S.Y. Dai; and technical and programming assistance by V. Kawka, Lucette Dell'Oso, Larry Wise, Reina Dubé, Patricia Johnston and Paul Fleury. Special thanks are due to Professor Norman Ryder for his technical note on developing fertility assumptions, and to Professor Ronald Lee for his methodological contributions in mortality projections.

Many thanks go to the Interdepartmental Working Group on Employment Equity who initiated and sponsored the project.

EXECUTIVE SUMMARY

This report presents female population projections by age for Canada, provinces, and territories from 1991 to 2016. The projections were prepared using Statistics Canada's regional cohort component approach, and are based on a combination of three fertility, one mortality, one international migration, and two interprovincial migration assumptions.

Using as the base population, the June 4, 1991 Census count, with an adjustment for population on incompletely enumerated Indian reserves, and excluding non-permanent residents; six series of projections were generated, which included all possible combinations of the above-mentioned assumptions on the components of population change. Three of these were then selected to provide a high, medium, and low scenario for Canada and the provinces. Although temporary residents were excluded from the base population, they were included in the projected population by adding them as a constant number each year.

The projection results indicate, that at the national level, regardless of the projection scenario considered, Canada's female population will grow at a slower pace than in the past, but in a similar pattern to males. However, the aging process among females will accelerate much faster.

Up to the year 2001, there will be no significant differences in the projected female population among the three scenarios. However, differences become noticeable in later years: under the high-growth scenario, the female population will grow to 18.7 million by 2016, compared to 18.1 million under the low-growth scenario.

Over the period 1991 to 2016 no radical change will take place in the proportion of females to the total population. In 1991 they accounted for 50.71 percent, under the medium-growth scenario this will increase to 50.72 percent, while under the low-growth scenario it will reach 50.75 percent. In contrast, under the high-growth scenario they will decline slightly to 50.68 percent. These variations in the proportion of females under the three scenarios can be explained by the sex ratio at birth, more male than female children being born at any one time.

In 1991, females aged 0 to 17 numbered 3.3 million, by 2016 they will reach between 3.5 and 4.0 million. According to the medium-growth scenario, females 18 to 64 will increase to 11.4 million by 2016 - up by 2.8 million from their 1991 level, while females aged 65 and over will age more rapidly from 1.8 million in 1991 to 3.3 million by 2016.

Results at the provincial level are less certain owing to the unpredictable effects of interprovincial migration. While the female population will grow at the national level throughout the projection period, within the range of projections selected there are cases where the female population will decline at the provincial and territorial level on an annual basis. In general however, the rate of growth of the female population in the provinces, though uneven, will decline fairly steadily in keeping with the trend of Canada's population as a whole.

INTRODUCTION

This report presents female population projections by age for Canada, provinces, and territories from 1991 to 2016. The projections were prepared using Statistics Canada's regional cohort component approach, and are based on a combination of three fertility, one mortality, one international migration, and two interprovincial migration assumptions (see Table 1).

Six series of projections were generated combining all possible combinations of the above mentioned assumptions on the components of population change. Three of these combinations have been chosen to provide a high, medium, or low growth scenario for Canada and the provinces. The selected projection scenarios, and the combinations of the varying component assumptions (fertility and interprovincial migration) are given below:

- 1.High: High fertility level and interprovincial migration pattern,'B'(HB)
- 2.Medium: Medium fertility level and interprovincial migration pattern,'A'(MA)
- 3.Low: Low fertility level and interprovincial migration pattern,'B'(LB)

On average, the projections generated from the combinations of component assumptions selected for this report showed the largest variation in the size of the projected female population for Canada and the provinces by the year 2016.

Section 1 describes the methodology, the base population and component assumptions. Section 2 presents a brief analysis of projection results. Finally, the appendix provides detailed tables of the three projections which were selected, and a summary table of the 3 projections which were not selected.

**Table 1. Base Population and Component Assumptions for Female Population,
Canada, Provinces and Territories, 1991-2016**

Projection Scenarios		Mortality Level (life expectancy at birth, in years)		Total Fertility Rate (number of children per woman)		Annual Immigration	Total Emigration Rate (in percent)	Interprovincial Migration
		1991	2016	1991	2016			
HA	M	74.2	78.0	1.80	2.05	250,000	0.1	A
	F	80.8	84.0	1.80	2.05	250,000	0.1	A
HB	M	74.2	78.0	1.80	2.05	250,000	0.1	B
	F	80.8	84.0	1.80	2.05	250,000	0.1	B
MA	M	74.2	78.0	1.80	1.85	250,000	0.1	A
	F	80.8	84.0	1.80	1.85	250,000	0.1	A
MB	M	74.2	78.0	1.80	1.85	250,000	0.1	B
	F	80.8	84.0	1.80	1.85	250,000	0.1	B
LA	M	74.2	78.0	1.80	1.65	250,000	0.1	A
	F	80.8	84.0	1.80	1.65	250,000	0.1	A
LB	M	74.2	78.0	1.80	1.65	250,000	0.1	B
	F	80.8	84.0	1.80	1.65	250,000	0.1	B

Note: Base Population: (1991 Census Count) - (non-permanent residents) + (population on incompletely enumerated Indian reserves). See Section 1.2.

HA - High fertility; interprovincial migration pattern A.

HB - High fertility; interprovincial migration pattern B.

MA - Medium fertility; interprovincial migration pattern A.

MB - Medium fertility; interprovincial migration pattern B.

LA - Low fertility; interprovincial migration pattern A.

LB - Low fertility; interprovincial migration pattern B.

Interprovincial Migration

A: Extrapolation of 1989 - 1991 interprovincial migration pattern (Westward migration, with concentration to B.C.).

B: Extrapolation of 1986 - 1988 interprovincial migration pattern (Ontario dominant migration).

1. METHODS AND ASSUMPTIONS

1.1 Projection Model

The general method used herein is Statistics Canada's regional cohort component model. There are two basic steps that are used for this model. The first step requires a separate analysis of the previous trends of each component of population growth - fertility, mortality and migration (interprovincial and international) - using appropriate demographic parameters. Secondly, these parameters, are generally in the form of absolute values, rates, and ratios, which are then extrapolated and added or applied to the population of the base year to obtain the future population by age and sex for each year and for each region. The national figures are then obtained by aggregating the projections for the provinces and territories.

The following subsections provide a summary of the inputs and specifications used in producing the current set of projections.

1.2 Base Population

The base population for these projections is the published 1991 Census count as of June 4, with an adjustment for population on incompletely enumerated Indian reserves; and excluding non-permanent residents. The base population was not adjusted to June 1, as the difference between the population counts on June 1, and June 4 would be negligible.

For each year of the projection period, a constant non-permanent resident population was added to the projected population from the base year onwards. This ensures that the non-permanent resident population is not cumulative.

1.3 Fertility

The cohort component projection model requires a set of projected age-specific fertility rates. By applying projected age-specific fertility rates to data for the number of females of the corresponding childbearing age, the projected total births were derived. The fertility age schedule was projected by applying the Pearsonian Type III curve, based on four indices: (1) the total fertility rate, measuring the level of fertility; (2) the mean age of fertility; (3) the variance of fertility (4) the skewness of fertility. The latter three provide a convenient measure of the age pattern of childbearing.

The assumptions regarding the fertility parameters (TFR and mean age) were first made at the national level. The values for the provinces and territories were then derived by analyzing the pattern of convergence among the regional indices.

Among the four fertility parameters, the total fertility rate is the most important index in projecting births. On the basis of trends in cohort and period fertility levels, low, medium, and high assumptions for the total fertility rate, and corresponding mean age of fertility were formulated as follows:

The Low Assumption: The total fertility rate for the country is assumed to decline from 1.80 births per woman in 1991 to 1.65 by 2016. This assumption is combined with a high mean age of fertility which increases from 27.8 years in 1991 to 28.0 years by 2016.

The Medium Assumption: The total fertility rate is assumed to increase slightly to 1.85 births per woman by the end of the projection period. Concomitantly, the mean age of fertility is assumed to decrease from its 1991 level of 27.8 years to 27.5 years by 2016.

The High Assumption:

The increasing trend in the total fertility rate observed in the years 1988 to 1990 is assumed to continue in the future, with the total fertility rate for Canada rising from 1.80 in 1991 to 2.05 births per woman by 2016. This assumption is combined with a low mean age of fertility decreasing from 27.8 years in 1991 to 27.0 years by 2016.

The projected total fertility rates and mean ages of fertility for the intervening years were obtained by fitting a curve of weighted least squares to the individual indices for the past ten years.

In order to keep the projection model simple, one assumption was developed for the other two fertility parameters, namely, the variance and the third moment of the fertility distribution. At the provincial level, these two parameters were projected as a function of the mean age of fertility. Using historical data from the period 1971-1989, regression analysis was performed, and the prediction models obtained were sufficiently significant to allow the variance and 3rd moment to be projected as a function of the mean age. The prediction model also allows for regional variations in the parameters.

Finally, the four parameter model of the Pearsonian Type III Curve, has been simplified into two parameters, the total fertility rate, and the mean age of fertility. The other two parameters (variance and skewness) were indirectly estimated from the projected mean age.

It should be noted that the Pearsonian Type III Curve fits the age specific fertility rate well when the μ_3 (skewness) value is greater than ± 1.0 . Whenever μ_3 is less than ± 1.0 , the value of μ_3 should be converted to ± 1.0 .

1.4 Mortality

One assumption is made for mortality in terms of life expectancy at birth (e_0). Two steps were involved in formulating this assumption. First, two assumptions, "high" and "low" were developed in terms of life expectancy at birth. Second, the average between the high and low assumptions was taken for the present set of projections (see Table 2). The high and low assumptions were developed as follows:

- (1) Six methods were used to project the e_0 's by sex at the Canada level. The results are presented in Table 2. The values produced by these various methods were then compared with the e_0 's used in the 1989 - based population projection series, and on the basis of consistency, the e_0 's for 2016 were selected (Table 2).
- (2) The provincial values were derived based on the ratio of the provincial/national life expectancy at birth.
- (3) The age-specific survival rates were calculated using the Lee-Carter equation $[l_n(m_x) = a_x + b_x k_t]$ and the usual life table equation. The old age (85+) mortality was calculated using the Coale-Kisker model.

Table 2 Projected e_0 's by Sex, Various Methods, and the Assumed Level, Canada, 2016

Methods	Male	Female
Analytical Report	78.3	84.4
Lee	76.5 ± 1.5	84.6 ± 1.0
Extrapolation of M_x		
30-Year trend	77.3	84.9
15-Year trend	78.8	84.4
Brass approach		
30-Year trend	77.8	85.3
15-Year trend	79.3	84.1
1989-based Population Projections	77.0	84.0
Projected e_0 in 2016		
High	77.0	83.0
Low	79.0	85.0

1.5 Immigration

- (1) At the Canada level, the number of immigrants is assumed to remain at 250,000 per annum from 1991 to 2016.
- (2) They are distributed by province using the average distribution of the last three years of observation, 1988 to 1990.
- (3) These are then distributed by age and sex within each province using an average of the flow of the last three years and 1991 Census stock data on immigrants arriving in the period 1988-90 as follows:
 - (a) The corresponding regional distributions are used for Ontario, Quebec and British Columbia, the Atlantic provinces and the Prairie provinces.
 - (b) The national distribution is used for the Yukon and the Northwest Territories.

1.6 Emigration

One assumption for emigration from Canada is made in terms of the total emigration rate (TER). The TER represents the sum of age-specific emigration rates. This concept is similar to the total fertility rate TFR which is the sum of age-specific fertility rates.

The various steps involved to project the emigration component are given below:

- (1) Calculate the specific emigration rate by age and sex for the provinces and territories for the years from 1976-77 to 1991-92, and sum the age-specific rates to get total emigration rates (TER).
- (2) Formulate the assumption for emigration. This was based on a 5-year average of the TER (the mean of the period 1987-88 to 1991-92) for the provinces and territories. It is assumed that this average TER level will be reached by 1996-97. The TER's between 1991 and 1996 were then obtained by linear interpolation. The emigration rate in 1996 was kept constant up to 2016.
- (3) For each year from 1976-77 to 1991-92, calculate the standardized distribution of the emigration rate by age and sex. This is done by dividing the age-specific emigration rate by the total emigration rate.
- (4) Calculate the 5-year average of the standardized distribution of emigration rates by age and sex in order to find a stable age-sex distribution of emigration.
- 5) The standardized distribution of emigration rates by age and sex, calculated in step (4), was then applied to the TER's obtained in step (2) and the specific emigration rate by age and sex between 1991 and 2016 for each of the provinces and the territories was thus obtained.

1.7 Interprovincial Migration

Two assumptions on interprovincial migration are made as follows:

Scenario A: This refers to the out-migration rates of the population by province that were based on the recent interprovincial migration trends of 1989, 1990 and 1991. This represents a Westward flow primarily favourable to British Columbia, and to a lesser extent, Alberta.

Scenario B: This refers to the out-migration rates of the total population by province that were based on the interprovincial migration trends of 1986, 1987, and 1988. This represents an Eastward flow centred primarily on Ontario.

These two scenarios, A and B were kept constant for the projection period.

The various steps involved in projecting migration by age and sex are the following:

- (1) The provincial crude out-migration rates (COR) and origin-destination matrices are used to produce the provincial net migration assumption ranges provided by the provincial statistical focal points. These net migration assumptions lie between scenarios A and B.
- (2) The assumed origin-destination matrices under scenarios A and B are kept constant throughout the projection period.
- (3) The gross migraproduction rate (GMR) is obtained by the summation of the age-specific migration rates. The GMR's are strongly correlated with the crude out-migration rates, however, research indicates that the GMR would be a more meaningful index of the propensity to migrate.
- (4) The assumed provincial crude out-migration rates are then converted into gross migraproduction rates by sex (GMR) using a ratio (COR/GMR) and a constant sex ratio.
- (5) Age-specific rates are then calculated using the Rogers-Castro model.

2. PROJECTION RESULTS

2.1 The Size of the Female Population and Future Growth

Regardless of which projection is considered, Canada's female population will grow at a slower pace than in the past, but in a similar pattern to males. However, the aging process among the female population will accelerate much faster compared to the male population.

According to the 1991 Census of Canada, the female population, including the non-institutional residents was 13.9 million. Under the medium-growth scenario, they will grow to 18.4 million by 2016 - an increase of 4.5 million over the twenty-five years (see Table 3 and Figure 1). Up to the year 2001, there will be no significant differences in the projected female population among the three growth scenarios.

However, differences among them are noticeable in the later years. Under the high-growth scenario, the female population will reach 18.7 million. Under the assumption that fertility will continue to fall (low-growth scenario), the female population will be lower, 18.1 million in 2016.

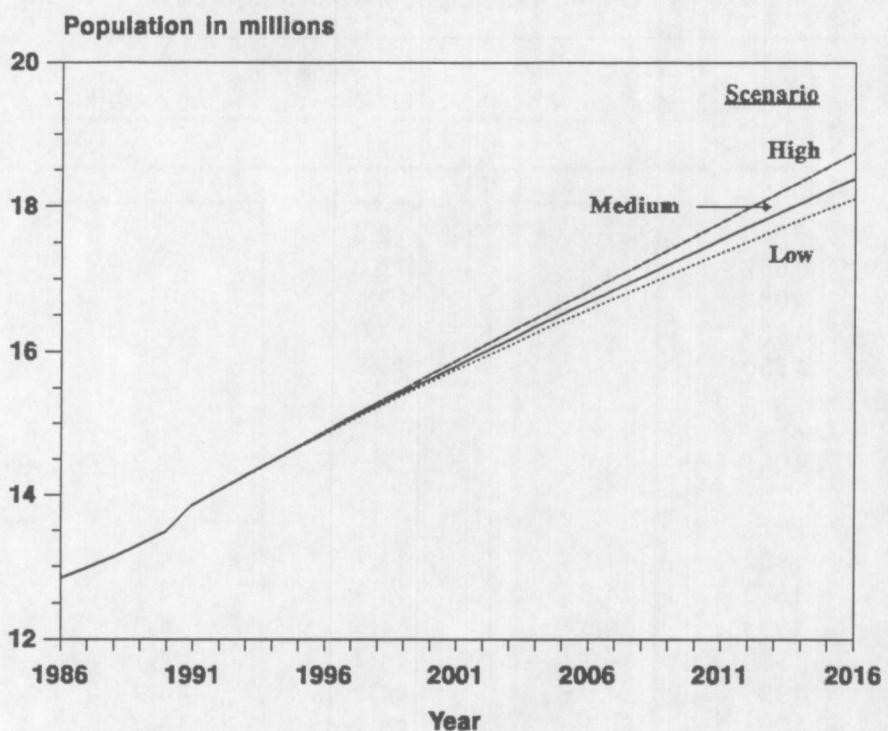

In 1991, the proportion of females to the total population was about 50.71 percent. By 2016, this ratio will increase slightly to 50.72 percent (under the medium-growth scenario); and 50.75 percent (under the low-growth scenario). In contrast, the ratio will decline slightly to 50.68 percent under the high-growth scenario. The sex ratio at birth with more male children than female children explains the observed variations in the proportion of females under the three scenarios.

Table 3. Trends in the Female Population of Canada, 1986 to 2016, According to Three Growth Scenarios (High, Medium and Low)

Year	Scenarios		
	High growth	Medium growth	Low growth
in millions			
Estimated			
1986		12.8	
1987		13.0	
1988		13.1	
1989		13.3	
1990		13.5

*1991 Census: As in Table 3.

Table 4. Projected Average Annual Rate of Population Change, Canada, 1991-1992 to 2011-2016, According to Three Scenarios

Period	High growth (a)		Medium growth (b)		Low growth (c)	
	Total	Female	Total	Female	Total	Female
	in percent					
1991-1996	1.43	1.44	1.41	1.42	1.38	1.39
1996-2001	1.29	1.29	1.22	1.22	1.17	1.17
2001-2006	1.18	1.18	1.09	1.09	1.03	1.03
2006-2011	1.12	1.11	1.02	1.01	0.93	0.93
2011-2016	1.07	1.06	0.95	0.95	0.86	0.86

(a) Medium mortality, high fertility and internal migration pattern B (1986-1988).

(b) Medium mortality, medium fertility and internal migration pattern A (1989-1991).

(c) Medium mortality, low fertility and internal migration pattern B (1986-1988).

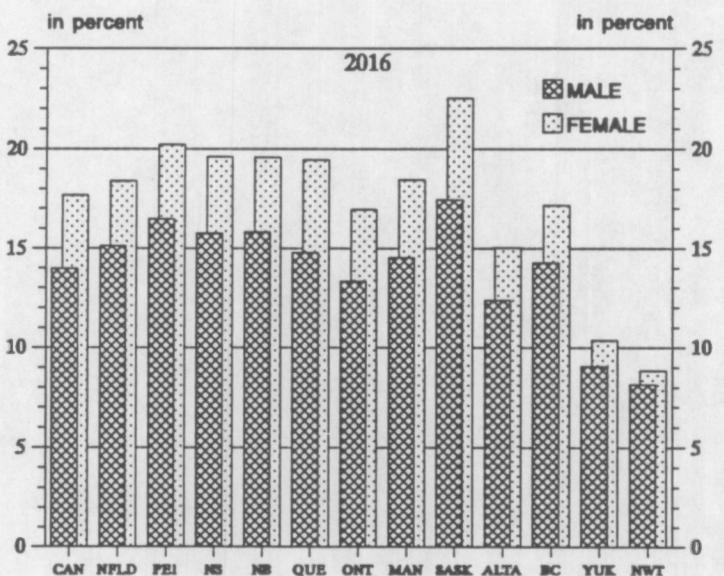

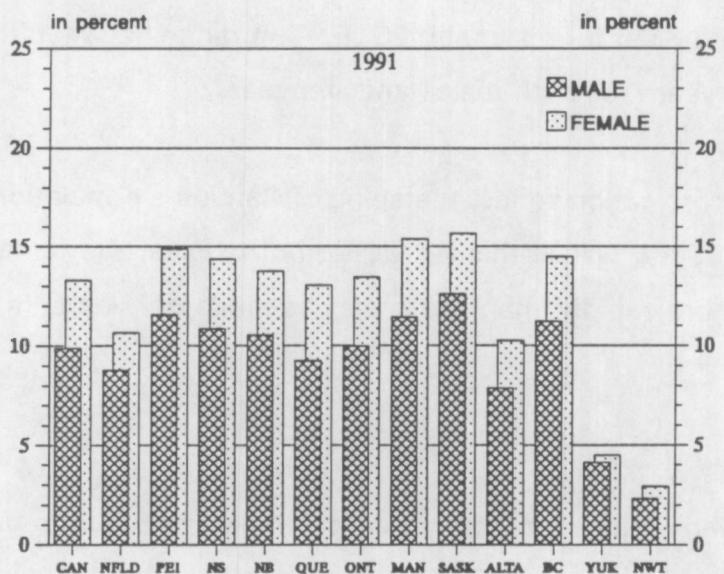

2.2 Changes in the Age Structure

The median age for the females in 1991 was 34.2, compared to the males which was 32.7. Based on the medium scenario, the median age would increase to 41.4 for females and 38.6 for males, by 2016. The range between the high and low scenarios was 1.3 years for both males and females.

Under all the projection series, the aging of Canada's population accelerates as a result of a low fertility. While this is true for both sexes, the female population is expected to age more rapidly than the male, because of women's higher survival rates.

In 1991 elderly females (aged 65+) accounted for 13.28 percent of the population, and elderly males for 9.88 percent. Under the medium-growth scenario, elderly females would increase to 17.67 percent of the population, and elderly males to 13.97 percent by 2016 (see Figure 2).

Figure 2 Percentage Distribution of Persons Aged 65+, by Sex, Canada and Provinces, 1991 and 2016 (Medium-growth Scenario)

In 1991, there were 3.3 million females aged 0 to 17 (the pre-school and school-age population). By 2016, their number is projected to reach between 3.5 and 4.0 million. Their projected number depends largely on the fertility assumption, as they move more and more away from the base year. The number of 18 to 64 is projected to reach 11.4 million by 2016 (medium-growth scenario), 2.8 million more than in 1991. The range between the high and low scenarios is quite low (64,300) due to the lesser effect of fertility on this age group. When considering the future number of women aged 65 and over, there is very little difference between the three scenarios. The cohorts who will make up this age group are already born. The projected size varies only through the international migration assumption (the mortality assumption is identical in all three scenarios). The 65 and over number will grow at a rapid pace. In 1991, the number of women in this age group was 1.8 million; by 2016, it would increase to 3.3 million (see Table 5).

Table 5. Broad Age Groups for Females, for the Three Projection Scenarios, 1991 and 2016

	1991	2016		
		High-growth Scenario	Medium-growth Scenario	Low-growth Scenario
		in thousands		
0-17	3328.8	4013.6	3701.2	3452.5
18-64	8691.4	11478.1	11441.3	11413.8
65 +	1840.4	3250.5	3251.0	3250.5

2.3 Provincial Trends

There is a much greater margin of uncertainty in the results at the provincial level. The reason for this is the presence of an additional growth factor, interprovincial migration, which is very unpredictable.

While the female population will grow at the national level throughout the projection period, there are some cases in the range of projections selected, where the female population at the provincial and territorial levels will actually decline on an annual basis.

In general, the rate of growth of the female population in the provinces, though uneven, declines fairly steadily in keeping with the trend projected for the Canadian population as a whole. The relative share of the female population among the provinces will change very slowly over the projection period. According to all of the projections, Ontario will continue to have the largest proportion; Quebec's proportion may decline slightly, but Alberta's and British Columbia's proportions would remain stable or increase depending on the projection scenario (see Table 6).

Table 6. Provincial Percentage Distribution of Female Population, 1991 and 2016, According to Three Scenarios

Province	1991*	2016		
		High Scenario	Medium Scenario	Low Scenario
Population in thousands				
Canada	13,860.7	18,742.1	18,393.5	18,116.8

* 1991 Census base population = Census count + (non-permanent residents) + (the population on incompletely enumerated Indian reserves).

3. LIMITATIONS OF PROJECTIONS INCLUDING THE IMPACT OF NET CENSUS UNDERCOVERAGE ON POPULATION PROJECTIONS

The accuracy of any projections is conditional on the reliability of the base population and component data, and the degree to which the underlying assumptions successfully anticipate future trends. Population change is influenced by various socioeconomic and/or political factors, which cannot be clearly foreseen, and whose impact on demographic changes cannot be accurately measured. In general, the uncertainty of future population change can be expected to increase over the projection period, and to be greater for smaller populations.

The base population for the current set of female projections is the 1991 census counts including an adjustment for refusals by the Native Peoples and the presence of non-permanent residents in the country. The 1991 Census counts are limited to the coverage bias. A study of the 1991 Census estimated that the net undercount rate was 2.87 percent for Canada, approximately 1.80 percent for Saskatchewan and 3.64 percent for Ontario. In the Yukon and Northwest Territories, the rates were 3.83 percent and 5.44 percent, respectively. The net undercount rate for the female population was much lower than that for the male population, 2.39 percent versus 3.37 percent. The study also showed that net undercoverage was not evenly distributed among age groups, that it tended to be higher among adults aged 20-24, where it reached 7 percent. In projecting the population, the 1991 level of undercoverage has been carried forward to future years, however the age pattern of undercoverage in the projected population will change, since it is the age cohorts and not the age groups which retain their initial rate of under coverage.

The impact of under-coverage on the base population has been evaluated in the past (see, Statistics Canada, 1990, Catalogue No. 91-520, p.46). The results of the previous evaluation showed that, "the projected population reflected the persistence of the same amount of under-coverage in the base population. For specific age groups, however, the difference between the two projections fluctuated more widely."

Statistics Canada will be adjusting the 1991 Census and post-censal population estimates for under-coverage. For the first time, the forthcoming Statistics Canada's population projections by age and sex for Canada, provinces and territories will be based on 1993 population estimates adjusted for net undercoverage in the 1991 Census.
