D.G. Saigaonkar

Senior Statistician (Education)

The views expressed in this report are those of the author and do not necessarily reflect the official views of the Department of Indian Affairs and Northern Development.

## ACKNOWLEDGEMENTS

The author wishes to gratefully acknowledge the constant co-operation received during the preparation of this report from the Education Operations Branch, the Computer Information Systems Division and from Mr. W. Zayachkowski, Chief, Program Statistics Division.

Special thanks are due to Mr. M.A. Sulutas and Miss G.T. Nelson for their help in field visits and to Mrs. P.J. Murphy for her painstaking and diligent typing.

Lastly but not the least, the author wishes to express his gratitude to the innumerable field staff and other respondents, without whose help this study could not have achieved its present status.

Ottawa, Ontario
October 29, 1976
D.G. Saigaonkar

Senior Statistician (Education).

A feasibility study in Kingston Education District was conducted in 1976 to develop a suitable statistical methodology for evaluating the Data Bank on enrolment of regiatered Indian students. That study also developed corrective measures to resolve different field problems.

The present report, presented in three parts, is primarily based upon techniques and measures developed by that study and covers a sample of 1,599 Indian children selected from another nine districts across the country.

Part A covers specific particulars like sample selection, sources and items of information, statistical techniques, time schedule, manpower and cost, assessment of objectives, recommendations and general observations.

Part B deals with the evaluation of the Data Bank based on all samples covered in the study using three different approaches. An error analysis and relevant tables and charts are supplied in this part.

Part $C$ gives a detailed evaluation of the Data Bank based upon individual samples from each of the nine Education Districts, supplemented by district leve1 tables.

Any suggestions and enquiries regarding this report may be directed to Mr. D.G. Saigaonkar, Senior Statistician (Education), Statistics Section, Program Statistics Division.

## PART A

## 1. Introduction

The Department of Indian Affairs and Northern Development maintains statistical records for all registered Indian students under its responsibility. An Education Data Bank has been developed to store the annual records of nearly 72,000 students beginning with the school year 1969-70.

The volume of data collected over the past six years and the diverse background of individuals associated with the collection, compilation, editing and processing of the data may affect the homogeneity and objectivity of the data bank. Realizing this, the Management Information Systems Working Group recommended in 1974 that a study of the Data Bank be undertaken to determine its reliability and to suggest corrective measures for its improvement. Consequently, in 1975, a feasibility study was carried out in Kingston Education District to develop suitable methodology and to identify and resolve probable field problems arising in this type of study.

In accordance with the recommendations of the feasibility study, reference years and statistical techniques for the sample selection were revised and a nation-wide study was conducted in early 1976. This report documents the revised sample selection and the methodology, analysis and recommendations of the main study.

## 2. Sample Selection

Since the Departmental responsibility to registered Indians residing on reserves is different from that to those who are off reserves, separate sampling techniques were necessary for the two types of Indian population. In the case of on-reserve population, ideally speaking, every Indian child of school-going age will be in school
and its educational responsibility will be borne by the Department. On the other hand, Departmental responsibility for the off-reserve Indian population is limited to counselling, provision of books and school supplies, and, in rare cases, the paying of tuition fees.

Nine Education Districts were selected in the sampling scheme, one from each of the administrative regions except in British Columbia where three districts were chosen because of interesting educational achievements of Indian community in that region. The choice of these districts was made in consultation with the district offices and was mainly based upon the diversity of field problems likely to be encountered in the study.

In order to ensure consistent coverage of school-going children for the entire reference period from 1970-71 to 1974-75 inclusive, it was decided to consider the registered Indian population born between 1960 and 1964 inclusive. Individuals from selected districts and ages were listed by residence of their parents; those of the same age were further arranged alphabetically.

Every twentieth person was selected for study from the lists of individuals with parents residing off reserve; this constituted Sample A. Since Departmental responsibility is greater in the case of Indians residing on reserve, every sixth person from the corresponding list was included in the study; this constituted Sample B.

## 3. Sources of Information

Most of the individuals selected in the samples were identified in the data bank and their particulars as retrieved from the data bank were
recorded in codes on compilation sheets specially developed for this purpose. (See Annexures $A$ and $B$ on pages 45, 46, 47 for details).

Attempts were made to obtain correct records of as many sample units as possible from the Education District Offices, respective schools, counsellors, teachers and liaison officers. In the absence of any records, information was collected from the informant as a last resort and identified separately for assessing its magnitude and impact on the overall findings of the study.

Any variation from field records was treated as a data bank error. Some bias may have been introduced in the final analysis by the use of personal knowledge in lieu of field records and by not being able to identify an individual by his registered name in the field.

## 4. Items of Information

The statistical information retrieved from the Education Data Bank is used for budgetary planning, program forecasts, feed-back to Education Districts, projections and other research requirements. Based upon their importance to these requirements, items of information were classified in three groups as follows:
(a) Essential - Home district, band code, family number, child position, year of birth, parents' residence, school number, school type (management), and grade;
(b) Acceptable - Day of birth, month of birth, type of course, student's accommodation, allowance and other facilities, and language(s) spoken by the student at first entry to school;
(c) Negligible - Spelling of student's surname and given name(s).

Any error in reporting an item from the essential group was considered serious enough to affect adversely the reliability of the student record. Comparatively speaking, an error in reporting an item from the acceptable group was not considered that serious while any spelling error in the student's surname or given name(s) was presumed to be negligible, thus having a minimal effect on the reliability of the student record.

Information on school attendance and use of native language in school is being collected beginning with the 1973-74 school year. Information on the sex of the student, though available in the Data Bank, was not considered to be pertinent for any policy planning. These items were not included in the study.

## 5. Methodology Employed

The data were analysed separately for Samples $A$ and $B$ and for each of the five school years under study using three different approaches, described in this section of the report.
(a) Criterion Grouping: If a student record, also referred to as a sample unit, had identical information in the data bank and field records with respect to at least five of the nine items of information from the essential group, it was assumed to have satisfied the essential criterion and was allotted to group E. A sample unit satisfying at most four items from the essential group was allotted to group e. In the case of the acceptable group, a student record was assumed to have satisfied the acceptable criterion only if it had identical information in the data bank and field records for at least four of the six items of information. Such a record was allotted to group A. All other records were allotted to group a.

Similarly, for allotment to group $N$, a student record was required to have identical information in the data bank and field records with respect to both items of information from the negligible group. Otherwise, the student record was allotted to group n.

The three criteria $E, A$ and $N$ and their absences, indicated by $e$, a and $n$, generated eight mutually exclusive classes, namely EAN, EAn, EaN, Ean, eAN, eAn, eaN, and ean. Each of the student records thus belonged to one of these eight classes depending upon the number of items of information observed as identical in the data bank and field records in each of the three criteria groups. The distribution of student records in these eight classes was then studied for an Education District to obtain an aggregate picture of reliability for that Education District. Finally, the distribution of all student records from the nine Education Districts was studied to arrive at an aggregate indication of reliability for all of Canada, for a given school year and sample type.
(b) Record Reliability: Each of the nine items of information from the essential group was assigned a weight of 0.08 . In other words, this meant that its contribution to the reliability of a student record was $8 \%$. The entire group of nine essential items thus carried a total weight of 0.72 or accounted for $72 \%$ of the reliability of a student record.

Each of the six items of information from the acceptable group was assigned a weight of 0.04 , the whole group thus accounting for $24 \%$ of the reliability of a student record. The two items from the negligible group were each given a weight of only 0.02
and contributed the remaining $4 \%$ of the reliability of a student record.

Mathematically speaking, this could be summarized by the following model:
$R x y=0.08 \mathrm{E}+0.04 \mathrm{~A}+0.02 \mathrm{~N} \quad$ where
Rxy is the reliability of a record $x$ for the school year $y$; and $E, A$ and $N$ are the number of items of information reported identically in the data bank and field records from the essential, acceptable, and negligible groups, respectively.

In an ideal situation, all nine items from the essential group, six items from the acceptable group, and both items from the negligible group would be identically reported in the data bank and field records. According to our model, the reliability index for such a student record would be:

$$
\begin{aligned}
\mathrm{R}_{(\text {ideal })} \text { or } \mathrm{R}_{(\max .)} & =\underline{0.08(9)}+\underline{0.04(6)}+\underline{0.02(2)} \\
& =0.72+0.24+0.04=1.00
\end{aligned}
$$

On the other hand, if none of the items were identically reported in the two sources of information,

$$
\mathrm{R}_{(\text {min. })}=\underline{0.08(0)}+0.04(0)+0.02(0)=\text { zero. }
$$

The reliability index thus assumes values between zero and one. The maximum contribution to the reliability index from the acceptable and negligible groups cannot exceed 0.28. Consequently, if an arbitrary lower limit of 0.85 is set for the reliability index for acceptance of a student record, a significant portion of 0.57 of the reliability index would have to come from the essential
group. This means that at least eight of the nine items from this group would have to be identically reported in the data bank and field records.

Depending upon the desired quality of records, this arbitrary lower limit could be changed. The record reliability indices for sample records could conveniently be averaged over samples in an Education District and over all samples to obtain aggregate record reliability indices for these areas.
(c) Item Reliability: A11 items of information were further studied individually for their own reliability. If a certain item of information was reported correctly in the data bank, in agreement with field records, for all sample units in an Education District, for a particular sample type and in a given school year, its item reliability would be one hundred. On the other hand, if it was not reported correctly in the data bank for any one of the sample units, its item reliability would be zero.

Mathematically, this could be described as $R_{a y}=\left(1-\frac{n}{N}\right) 100$ where $R_{a y}$ is the item reliability of an item a for the year $y, n$ is the number of student records in which item a has been reported in the data bank in a manner different from that reported in field records, and N is the total number of student records being considered from an area.

An aggregate of item reliabilities over all eighteen items could obviously be worked out over a certain area for a given school year. This would be identical with the corresponding aggregate record reliability index for that area and school year obtained in the manner discussed in paragraph (b) above.

## 6. Time Schedule

The band membership lists as of December 31,1970 to December 31 , 1974 were used for selecting and identifying the sample units.

The data retrieved from the enrolment data bank and collected from the field records had a reference date of September 30 for each of the school years from 1970 to 1974 inclusive. The current data used for reference and identification of a sample unit in the field was as of October 31,1975 and was taken from the Nominal Roll recently received from the field.

The study was initiated in November of 1975 when selection of the Education Districts and sample units and the formulation of the frame design were completed. Retrieval of records from the enrolment data bank was carried out in December, 1975. Field visits were completed during February to April of 1976. The compilation and tabulation of the data was carried out in July-August, 1976 while the analysis and report writing was done in September, 1976.

## 7. Manpower and Cost

The entire study was designed, developed and executed by the Senior Statistician (Education) in about sixty days. He was assisted by a statistician and a statistical support officer both of whom together put in approximately thirty days of field work. The compilation, carried out by statistical clerks, required about fifty man-days.

The travel costs incurred in field visits amounted roughly to $\$ 4,700$; the cost of retrieval of data from the enrolment data bank was $\$ 200$; and the cost of printing forms and the report was approximately $\$ 100$.

## 8. Responsibility

The Education Operations Branch of the Indian and Eskimo Affairs Program was administratively responsible for the study and provided funds for field visits by members of the study team to obtain records from the nine Education Districts covered in the project.

## The former Departmental Statistics Division and the present Program

 Statistics Division developed and organized the project, and supplied the required manpower for the study.The Computer Information Systems Division provided initial band membership lists and student lists, and retrieved information for the selected sample units for the school years under reference.

The Education District Offices in Fredericton, Montreal, Sioux Lookout, Winnipeg, Brandon, Yorkton, Lethbridge, Nanaimo, Prince Rupert and Vancouver provided available information on sample units from their respective areas, and arranged for visits to certain schools and for discussions with counsellors, band officials and teachers having the necessary field records.

## 9. Assessment of Objectives

A suitable technique to evaluate the enrolment data bank was achieved by this study. Various problem areas contributing to discrepancies in the data bank were identified and corrective measures could now be taken to resolve such problems.

Major observations and recommendations on the study are discussed briefly in the next two paragraphs. A detailed evaluation for all samples combined and for the samples by Education District is given in Parts $B$ and $C$, respectively.

## 10. Major Observations

1. From Table 1 on page 34, it can be seen that the population of registered Indians in the age group 10 to 14 inclusive was 12,120 as of December 31, 1974. Of these, 8,593 were reported as residing on reserve, and 3,527 were reported as being off reserve.

As many as 169 children from the off-reserve population constituted Sample A and 1,430 children of on-reserve status comprised Sample B.

The number of sample units for which field records were available ranged between $38 \%$ and $45 \%$ of the total sample size for off-reserve children. Since their education responsibility does not rest with the Department, these low percentages are not surprising. In the case of on-reserve children, field records were available in the range of $81 \%$ to $88 \%$ of the sample units over the period under review.
2. Table 2 on page 35 analyzes various reasons for which information on some sample units was missing from field records. Frequent migration to and from reserves, different ways of maintaining student records, and isolation of certain areas are some of the important reasons. In case the enrolment data bank also had no information on some sample units, it would totally agree with the field records for these sample units and eventually yield a perfect reliability index for such sample units. The number of such cases ranged between 72 and 96 for Sample A and between 130 and 208 for Sample B over the five-year period.
3. Table 3 on page 37 gives the distribution of sample units by mutually exclusive criterion groups which are explained earlier in paragraph 5(a). A broad idea about the quality of data is obtained from this tahle.

Out of 169 sample units in Sample $A$, as many as 131 to 154 units satisfied the essential criterion, since these units had at least five essential items of information in agreement in the data bank and field records. Of these, sample units ranging between 100 and 144 had at least four items from the acceptable group and both items from the negligible group in agreement and consequently, satisfied all the three criteria.

In the case of Sample $B$ comprising of 1,430 sample units, the range of student records satisfying the essential criterion was between 1,203 and 1,272. From these sample units, as many as 1,038 to 1,137 further satisfied the acceptable criterion. The sample units satisfying all three criteria were in the range of 1,033 to 1,134 .
4. Table 4 on page 38 gives a further breakdown of the sample units satisfying the essential criterion by Education Districts. It also indicates that most of the records satisfying the essential criterion also succeed in satisfying the remaining acceptable and negligible criteria.

It was observed that nearly $78 \%$ to $91 \%$ of the sample units from Sample A and $84 \%$ to $89 \%$ of the sample units from Sample B satisfied the essential criterion.

The corresponding ranges for sample units satisfying all three criteria were $59 \%$ to $85 \%$ for Sample A and $72 \%$ to $79 \%$ for Sample B.
5. Table 5 on page 39 supplies aggregate record reliability indices by Education District, school year and sample type. Contributions from the three mutually exclusive criterion groups are also given in this table.

The aggregate (total) reliability indices for all sample A units for off-reserve individuals ranged from 0.71 to 0.88 . For sample $B$ units, these indices were between 0.74 and 0.84 . Contribution from the essential items of information ranged from 0.51 to 0.63 for the sample $A$ units and from 0.54 to 0.61 for the sample $B$ units. Consequently, we could conclude that the records for on-reserve persons were more homogeneous than those for off-reserve persons over the five school years under study.
6. The aggregate record reliability indices discussed earlier are grouped in twenty equal class intervals of 0.05 each, in table 6 on page 40 for studying their frequency distributions for both sample types and over the five school years.

As many as $8 \%$ to $18 \%$ of the sample $A$ units had a record reliability index of minimal value. For sample B units, $6 \%$ to $11 \%$ of the records exhibited the minimum record reliability index. On the other hand, $54 \%$ to $77 \%$ of the sample A units had a perfect reliability index while only $10 \%$ to $42 \%$ of the records from sample B achieved this level.

A statistical analysis of the distribution of sample records in these classes further confirmed that the grouped averages of record reliability indices were in close agreement with those obtained in table 5 earlier. The variation of individual record reliability indices from these averages was also studied at this stage. The average variation, statistically known as the standard deviation, ranged from 0.28 for the school year $1974-75$ to 0.38 for the school year 1973-74 for Sample A records. For sample B
records, the least standard deviation of 0.27 was observed for the school year 1974-75 while the largest standard deviation of 0.31 was recorded for the school year 1970-71. This once again confirmed the homogeneity of sample $B$ records. Some charts indicating the frequency distribution of the sample records by record reliability index are given on page 43 of this report.
7. As discussed in paragraph 5 (c) above, item reliability indices were calculated for seventeen items of information for both types of sample units over the five school years under study. The results are given in table 7 on page 41 of this report. It was observed that the reliability of information on home district, band code, family number, child position and year of birth was identical for a given school year in sample A. For sample B units, slight variations were recorded amongst reliability indices for these items of information. The arithmetical average over the five-year period for these items in sample A was $83 \%$, somewhat lower than the corresponding average item reliability index of $87 \%$ observed for these items in sample B records.

The information on reporting students' names was the most reliable, $94 \%-95 \%$ in sample $A$ and $93 \%$ in sample $B$, while that on allowance was the least reliable, $70 \%$ in sample $A$ and $55 \%$ in sample $B$.
8. A comparison among the three approaches to judge the reliability of records was obviously necessary. This was carried out and the results are given in table 8 on page 42 . The proportion of records satisfying the essential criterion, the aggregate record reliability index and the average item reliability index for items from the essential group were used for this comparison.

It was observed that the proportion of records satisfying the essential criterion was, on the whole, greater than either of the other two reliability indices for a given Education District and school year for both sample types. This proportion ranged from 0.75 to 0.91 for sample $A$ records and from 0.84 to 0.89 for sample $B$ records. An interesting thing to note was that the record reliability indices more or less synchronized with the average item reliability indices for the essential items for almost a11 Education Districts and school years.

The similarity of the two indices establishes some validity of the statistical models developed for this study and discussed above in paragraphs $5(\mathrm{~b})$ and $5(\mathrm{c})$.
9. A relationship between the number of student records available in the data bank and field records for Sample B (see table 2 A on page 35 ) was established using a statistical technique known as regression. Chart II on page 44 indicates this relationship and enables us to estimate the number of student records that could be available in one source, given the number of records from the other source of information.
10. The differences among the proportions of units from Sample B satisfying the EAN criteria over the five school years under study could be attributed mainly to chance fluctuations. This was established by employing another statistical technique known as the Kruskal-Wallis one-way analysis of variance. See Annexure $C$ on page 48 for details.
11. The record reliability indices for Sample B units obtained for the five school years under reference could also be treated to be similar to each other. The differences observed among these
indices were proved to be insignificant and attributable to chance by using a Chi-square test for $k$ independent samples. See Annexure D on page 50 for details.

The same data were tested for variation among the nine Education Districts for all the school years by using another technique known as the two-way analysis of variance. The results are given in Annexure $E$ on page 52 of this report.
12. The item reliability indices in sample $B$ were also tested for their homogeneity over the school years $1970-71$ to $1974-75$ inclusive by using a statistical technique developed by Friedman. See Annexure F on page 54 for the details. The test established that any differences among the item reliability indices for this group are incidental and could be attributed to sampling fluctuations.

## 11. Recommendations

1. Assuming the validity of our statistical model, a record reliability index of 0.77 will ensure that at least seven of the nine essential items are identically reported in the data bank and field records. Setting this as the lowest limit for acceptance of a record, we may divide the sample units into two groups. Those reflecting an index of at least 0.77 may be considered to belong to the acceptance group while those having an index of at most 0.76 may be considered to constitute the rejection group.
2. The acceptance group may be further subdivided into (a) an ideal group having a record reliability index of at least 0.93 , thus ensuring identical information on all nine essential items from both the data bank and field records; and (b) a tolerable group with
reliability indices ranging from 0.77 to 0.92 , ensuring that seven or eight essential items tally from the two sources of information.
3. Based upon these norms, sample A records for the school year 1974-75 and sample B records for the school years 1971-72 to 1974-75 show reasonable reliability for all units as a whole.
4. Data bank records for sample B units for the school year 1970-71 need some improvements before they are accepted for any research purpose.
5. From sample A units, the data bank records for school years 1970-71 to 1973-74 also need some corrections before these could be re1iab1y used.
6. Regular updating of the cumulative record cards for the registered Indian students at the Education District office seems desirable. This alone could have reduced the number of ineffective sample units for the present survey anywhere from one-ha1f to two-thirds.
7. Information on allowances collected up to the school year 1973-74 was scanty, incomplete and incorrect in many cases. This item not only had the least reliability index of 0.55 for sample B units, but also lowered the aggregate reliability index considerably. The discontinuation of this item of information from the school year $1974-75$ seems justified in view of our findings.
8. In view of the volume of data, the diversified background of persons handling the collection, processing and analysis of the data, and the significant role the data play in policy development, education research and program forecasts, a quinquennial evaluation of the data bank through such sample surveys seems essential.

## PART B

This part of the report documents the evaluation of the Enrolment Data Bank on the basis of all samples covered in the study. The general approach of the analysis would be to present a comparative picture among the nine Education Districts and among the five school years under reference.

## 1. Evaluation Based Upon Table 1

The population of registered Indians in the age group 10 to 14 as of December 31, 1974 was considered as the basis for this study. Table 1 on page 34 presents this population along with the sample size and sample units effectively available for study by Education District by school year for the on and off-reserve types of population.
1.1 A sample of 169 children was available from the off-reserve population of 3,527 registered Indians. Manitoba accounted for $34 \%$ of this number, mainly due to its centralized administration. British Columbia also covered another $34 \%$ of the population through the selection of the Vancouver, Nanaimo and North Coast Education Districts for the study. Yorkton (14\%), Sioux Lookout (6\%), Montreal (5\%), Blood-Peigan (4\%) and New Brunswick (3\%) represented their respective regions in proportion to the corresponding populations.
1.2 Information on some of the sample units selected in the study was not available from the field records. In the North Coast Education District, for example, none of the 17 sample A units could be studied for want of field records. On the other hand, all six sample units from New Brunswick and as many as 41 to 43 sample units out of a total of 57 units from Manitoba were available for the study. The low numbers of sample units effectively available for study from the respective total number of sample $A$ units chosen for the study were mainly due to the restricted educational responsibility of the Department towards the off-reserve registered Indian community.
1.3 As many as 1,430 registered Indian children of on-reserve status were included in sample $B$, representing a total population of 8,593 individuals in the selected age group. Once again, Manitoba accounted for the largest share, nearly $32 \%$ of the population. British Columbia contributed one-fourth through its three Education Districts. Sioux Lookout and Blood-Peigan each accounted for $11 \%$ of the sample while Montreal ( $8 \%$ ), Yorkton (7\%), and New Brunswick (6\%) accounted for the remainder in proportion to the respective on-reserve populations.
1.4 Information on $86 \%$ of the sample units was available in the data bank and in the field records, on an average, over the nine Education Districts under reference. Once again, New Brunswick had the highest average percentage (95\%) of available records over the period under reference. It had $100 \%$ coverage for every school year except 1970-71. The Yorkton Education District, on the other hand, had the least coverage of $61 \%$ for the school year $1973-74$ and also recorded the least average coverage of $67 \%$ over all the five school years included in the study.

## 2. Evaluation Based Upon Table 2

The student records for which no information was available in the field were analyzed for the cause of their ineffectiveness by sample type, school year and their consequential impact on the reliability of the enrolment data bank. Table 2 on page 35 presents this error analysis. 2.1 Considering all sample A units having no records in the field over the five school year period, it was observed that $83 \%$ of these units had no information in the enrolment data bank also. Since these units, technically speaking, had identical information in both the data bank and the field records, these are indicated under the column entitled one in table 2. The remaining $17 \%$ units showed a total variation in the two sources of information and hence are presented in the next columns entitled zero.
2.2 Of the sample units shown under column one, it was observed, on an average, that over the period under reference
(a) $30 \%$ were no longer Departmental responsibility;
(b) $28 \%$ were unknown to the field personnel;
(c) no records were available in the field for $24 \%$ of the cases;
(d) $9 \%$ were studying in the States;
(e) $6 \%$ were in the care of provincial authorities and institutions 1ike Children's Aid Society; and
(f) $3 \%$ were not registered Indians at one time or another before December 31, 1974.

In the case of sample units shown under column zero,
(a) $58 \%$ were no longer Departmental responsibility;
(b) $28 \%$ had no records available in the fie1d;
(c) $12 \%$ were with the provincial authorities; and
(d) the remaining were not registered at one time or another before December 31, 1974.
2.3 From the sample $B$ units having no records in the field over the five-year period, it was seen that as many as $76 \%$ had no information in the data bank also. These are presented under column one of table 2 . The remaining $24 \%$ had complete records in the data bank and consequently showed total variation between the two sources of information. These are given under the column entitled zero in table 2.
2.4 Of the sample units shown under columm one, it was observed over the period of reference that
(a) $31 \%$ had no field records available for verification;
(b) $26 \%$ were studied on the basis of informant's guesswork in lieu of records;
(c) $19 \%$ were not a Departmental responsibility;
(d) $12 \%$ were under provincial jurisdiction;
(e) $6 \%$ were not known to the field personne1; and
(f) another $6 \%$ were studying in the States.

In respect of the ineffective sample units having information in the data bank, it was observed over the five school years that
(a) no records were available in the field for $63 \%$ of the cases;
(b) $20 \%$ of the students were not a Departmental responsibility;
(c) $7 \%$ were located under provincial jurisdiction; and
(d) the remaining $10 \%$ were unknown to the field personnel for one reason or another.

## 3. Evaluation Based Upon Table 3

The eight mutually exclusive classes generated by three groups of essential, acceptable and negligible items of information broadly indicate the reliability of student records. Table 3 on page 37 presents the distribution of student records in these classes over the five school years for both types of samples.
3.1 On an average over the reference period of five school years, two-thirds of the student records from Sample A comprising of 169 units satisfied all the three criteria and belonged to the group EAN. Another one-sixth of the records satisfied the essential and negligible criteria but had three or fewer items of information from the acceptable group for which the data bank and field records were in agreement. These accordingly belonged to the group EaN. Nearly nine percent of the student records correctly reported only the names of the students but were incorrect in both the essential and acceptable groups. About seven percent did not achieve even this accuracy and were totally inaccurate in the data bank.
3.2 A similar analysis of 1,430 sample $B$ units over the five school-year period indicates that a little over three-fourths of the student records satisfied all the three criteria and belonged to the group EAN. Another ten percent did not meet the acceptable criterion but satisfied the essential and negligible criteria and belonged to the group EaN. As many as $8 \%$ of the student records unable to meet the essential criterion but satisfying the negligible criterion were equally divided between the acceptable and non-acceptable groups. The remaining six percent of the records failed to meet any one of the three criteria; this means that the enrolment data bank had almost all inaccurate entries in their respect.

## 4. Evaluation Based Upon Table 4

The inter-district comparison of student records satisfying various criteria has been presented in table 4 on page 38 of this report.
4.1 For the period under review, $83 \%$ of the student records from Sample A satisfied the essential criterion. Montreal and Manitoba, with $100 \%$ and $96 \%$ of the student records, respectively, satisfying the essential criterion, were the leading Education Districts while Blood-Peigan (37\%) was the last Education District in this regard. On the whole, two-thirds of the student records from Sample A belonged to both the EA and EAN groups, indicating that there was no further loss of reliability of the data due to the information from the negligible group. In other words, we may conclude that the records which reported satisfactorily in respect of essential and acceptable items of information also reported correctly with respect to the students'
names and surname. The Montreal and Blood-Peigan Education Districts were once again at the extreme ends of the rating scale, with $90 \%$ and $31 \%$ of the student records, respectively, satisfying all the three criteria.
4.2 In the case of sample B records, the overall performance was slightly better than that for the Sample A records. Nearly $86 \%$ of the records satisfied the essential criterion. Montreal (97\%), Manitoba (96\%), Nanaimo (95\%), and Vancouver (94\%) were the 1eading Education Districts while Blood-Peigan (63\%) was again at the other extreme.

About $10 \%$ of these records, on the whole, failed to meet the acceptable and negligible criteria. A few of the records from New Brunswick and Yorkton satisfied the essential and acceptable criteria but lost credibility in the negligible group. It is significant to note that $20 \%$ of the records in the Montreal Education District did not meet the acceptable criterion while Nanaimo lost only one percent of the records in this respect. Consequently, with $94 \%$ of its student records satisfying all the three criteria, Nanaimo was the leading Education District while Blood-Peigan (62\%), once again remained at the bottom of the scale.

## 5. Evaluation Based Upon Table 5

In accordance with the model discussed earlier in paragraph $5(\mathrm{~b})$ of Part $A$ of this report, aggregate reliability indices were determined for each of the nine Education Districts for each of the five school years under review. Table 5 on page 39 presents these indices and the contributions they received from the essential, acceptable and negligible groups.
5.1 For Sample A records, the highest aggregate record reliability index of 0.88 was achieved in the school year 1974-75. The index had the lowest value of 0.71 in each of the school years 1971-72 and 1972-73. The aggregate indices for the school year 1973-74 and 1970-71 were 0.73 and 0.75 , respectively. Considering all sample A units over the period under review, we may conclude that a little over three-fourths of these units had identical records in the data bank and in the field. The Montreal Education District had the highest reliability index of 0.95 for Sample A units for all the school years combined while North Coast registered the lowest reliability index of 0.52 only.

Only the Montreal Education District achieved the distinction of having an ideal reliability of records, for the school year 1970-71. The Sioux Lookout Education District came close to this achievement when it presented a reliability index of 0.98 for the school year 1974-75. The lowest value of the reliability index was 0.23 for Blood-Peigan Education District for its records for the school year 1972-73. Another low index of 0.37 was recorded in the North Coast Education District for the school year 1973-74.
5.2 In the case of Sample B units, the school year 1974-75 registered the highest aggregate record reliability index of 0.84 . This index decreased slowly with each preceding school year, the least one being 0.74 for the school year 1970-71. On the whole, nearly four-fifths of the student records from Sample B were identically reported in the data bank and the field, the district percentages varying from a low of $65 \%$ in the Sioux Lookout

Education District to a high of $88 \%$ in the Nanaimo Education District.

The highest record reliability index (0.92) was recorded in the North Coast Education District for the school year 1974-75, closely followed by New Brunswick with 0.91 for the school year 1973-74 and Nanaimo with 0.90 for the school year 1974-75. On the other hand, Sioux Lookout recorded the pair of lowest indices, 0.57 and 0.58 , for the school years $1971-72$ and $1972-73$, respectively.

## 6. Evaluation Based Upon Table 6

Table 6 on page 40 presents the frequency distribution of the record reliability indices for all sample $A$ and $B$ units over the five school years under review. For the sake of convenience in statistical analysis, these indices are grouped into twenty classes with intervals of 0.05 . A quick glance at the table indicates that the records are clustering at the beginning, the middle and the end of the scale.
6.1 Considering sample A units over all the school years, it was observed that $15 \%$ of the records had a reliability index in the range of 0.50 to 0.54 , while $60 \%$ of the records had the maximum reliability index of one.

The number of student records with the maximum reliability index was about 94 for each of the school years except for $1974-75$, when 130 records had the perfect reliability index.

One-half of the student records, on the whole, had a reliability index greater than 0.99 , the median value of this distribution.
6.2 For Sample B units, over the entire five school-year period, the minimal value of the reliability index was recorded by $9 \%$ of the units. As many as $10 \%$ of the sample units belonged to the middle class with a reliability index of 0.50 to 0.54 , and $28 \%$ achieved the perfect reliability index. Nearly $57 \%$ of the records had a reliability index of 0.90 or more.

The number of student records with a reliability index of one, steeply increased from 143 ( $10 \%$ of the total) in the school year 1970-71 to 598 ( $42 \%$ of the total) in the school year 1974-75. This is quite satisfactory and fairly indicates that the quality of the data bank has substantially improved with every successive school year.

On the whole, one-half of the student records had a reliability index greater than 0.93 , the median value for the frequency distribution of sample $B$ units.

## 7. Evaluation Based Upon Table 7

According to present procedures, the computer identifies any student record by the home district, band code, family number and child position of the individual. If these are all in agreement with the data bank, further confirmation is sought for with information on the day, month and year of birth. Once this confirmation is received, the record is accepted and added to the data bank.

The information about parents' residence is also vital in determining the Departmental responsibility of the students. The different budgetary provisions for the federal, provincial, band-administered and private schools make the information regarding the type of school an essential item. The school number deciding the geographical location of the student and the grade indicating the student's level of achievement are similarly treated as items of importance to the Program. Table 7 on page 41 presents the reliability indices for the various items of information by school year for each of samples $A$ and $B$.
7.1 For Sample A records, the highest item reliability index was 96 when the surnames and given names of the students were correctly reported for the school year 1970-71. These items were satisfactorily reported on the whole, the least value of the index being 92 for the school year 1973-74.

Also, the highest reliability index for each of home district, band code, family number, child position, day of birth, month of birth and year of birth was also 92 , and was attained during the school year 1974-75. The information on allowances attained the least reliability index for the school year 1971-72 when only $60 \%$ of records were correctly reported in the data bank. Important items like the type of school and grade were reported with only $62 \%$ accuracy during the school year 1971-72. The average item reliability index over the entire five school years under review was 79 for all sample A records.
7.2 Considering sample $B$ records, it was observed that the highest item reliability index was 95 for the surname of the students
during the school year 1974-75. Once again, the overall reporting of both the surname and the given name of the students was quite satisfactory, with the least reliability index of 92 achieved for each of the itmes during the school year 1970-71.

Among other items from the essential and acceptable groups, the band code, family number, child position and the year of birth achieved the highest reliability index of 90 during the school year 1974-75. Surprising1y, information on allowances had the lowest reliability index of a meagre 16 for the school year 1970-71; the closest to this index was 50, again for allowances, during the next year.

The average reliability index for all items in sample $B$ for the entire period under review was 80 , just a bit more than the corresponding average reliability for the sample A records.

## 8. Evaluation Based Upon Table 8

The accuracy in reporting the items from the essential group is vitally important to the Program. Consequently, the proportion of records satisfying the essential criterion of the total number of student records was considered as an important item of analysis. Incidentally, it may be pointed out that records satisfying the essential criterion also tend to satisfy the acceptable and negligible criteria. In other words, persons careful enough to record information on the essential items like identification number, year of birth, and grade are likely to be careful in reporting information on the remaining items as well. The higher proportions under columns A of table 8 on page 42 substantiate this observation.

In the second approach entitled $B$, different weights were attached to the items belonging to the three groups in accordance with the relative importance of these items. As such, the aggregate record reliability indices for the Education Districts and all samples are considered pertinent for comparison.

The remaining approach of the item reliability index once again treats each item separately. For the sake of consistency and importance of accuracy in reporting information on items belonging to the essential group, the average reliability index for these items only has been used for comparison and shown under columns $C$ of table 8.
8.1 A closer analysis of the indices presented in Table 8 indicates that for the sample A units, in $58 \%$ of the cases on the whole, the indices by the three approaches were within three percentage points of each other. In $13 \%$ of the cases, they differed from each other by more than twenty percentage points; and the greatest difference of twenty-three percentage points occurred in Blood-Peigan for the school year 1972-73. We may conclude, therefore, that each of the three approaches substantiates the validity of the results to the same extent.
8.2 A corresponding analysis of the indices for Sample B units indicates that over the five school years under study, $40 \%$ of the cases had the indices by approaches $A, B$ and $C$ within four percentage points of each other. These indices were apart from each other by fourteen percentage points in only $14 \%$ of the cases. The greatest difference was twenty percentage points in Manitoba for the school year 1970-71.

The data for sample $B$ units seem to be more homogeneous than those for Sample A units. All the three approaches once again establish credibility of the methodology applied in the analysis of the data and also establish their own co-relationship.

TABLE 1
REGISTERED INDLAN POPULATION AGE-GROUP 10-14; SAMPLE SIZE AND UNITS EFFECTIVELY AVAILABLE FOR SIUDY BY RESIDENCE, SCHOOL YEAR AND EDUCATION DISTRICT

| $\mathrm{~T}_{\mathrm{j}}$ | 6 | 6 | 24 | 6 | 6 | 24 | 24 | 24 | 6 | 6 | 6 | 6 | 6 |

Null Hypothesis ( $H_{o}$ ) : There is no real difference within a given Education District in the percentages of sample units satisfying the EAN criterion over the five school years under study.

Kruskal-Wallis One-Way Analysis of Variance formula* is :
$H=\frac{12}{N(N+1)} \sum_{j=1}^{K} R_{j}^{2} /_{n_{j}}-3(N+1) ; \quad$ Correction for tied ranks is $1-\frac{\sum T_{j}}{N^{3}-N}$;
In our study, $N$ is $45 ; n_{j}$ is $9 ; R_{j}$ has $177,213,225,183.5$ and 236.5 values and $T_{j}$ is 150 Therefore, H equals $\frac{12}{45 \times 46}\left[\frac{177^{2}}{9}+\cdots \cdots \cdots+\frac{236.5^{2}}{9^{0}}\right]-3 \times 46=1.73$ and the correction for tied ranks equals $1-\frac{150}{91080}$ or 0.9984 giving us the value of
corrected H as $1.73 / 0.9984$ or 1.7328 .

Since the probability associated with the occurrence under $H_{o}$ of a value as large as $H=1.7328$ for degrees of freedom $k-1=4$ is between 0.70 and 0.80 *, we do not reject $H_{o}$. That is, we conclude that the observed differences in the percentages may be due to chance fluctuations.

| Nanaimo | . 83 | . 81 | . 89 | . 87 | . 87 | . 88 | . 89 | . 89 | . 90 | . 93 | 4.38 | 4.38 |
| North Coast | . 82 | . 79 | . 82 | . 84 | . 82 | . 85 | . 85 | . 86 | . 92 | . 90 | 4.23 | 4.24 |
| Vancouver | . 80 | . 77 | . 81 | . 82 | . 81 | . 83 | . 83 | . 84 | . 88 | . 88 | 4.13 | 4.14 |
| TOTAL | 6.61 | 6.61 | 7.07 | 7.08 | 7.12 | 7.13 | 7.20 | 7.21 | 7.53 | 7.53 | 35.53 | 35.56 |

Obs.: Observed Value (Oij); Exp.: Expected Value $\left[E i j=\left(\sum_{i} X_{i j}\right) \times\left(\sum_{j} X_{i j}\right) \div\left(\sum_{i} \sum_{j} X_{i j}\right)\right]$ * Null Hypothesis (Ho): There is no difference among the aggregate record reliability indices for different school years.

$$
\begin{aligned}
& X^{2}=\sum_{i=1}^{r} \sum_{j=1}^{k} \frac{(O i j-E i j)^{2}}{E i j} \quad \text { We have } 9 \text { rows, hence } r=9 ; \text { and } 5 \text { columns, hence } \\
& \\
& k=5 ; \text { therefore degrees of freedom }=(r-1)(k-1) \\
& \\
& =(8) \times(4)=32
\end{aligned} \quad \begin{aligned}
& =\frac{(.60-.76)^{2}}{.76}+\frac{(.81-.78)^{2}}{.78}+\ldots+\frac{(.92-.90)^{2}}{.90}+\frac{(.88-.88)^{2}}{.88} \\
& =12.84
\end{aligned}
$$

Since the probability associated with the occurrence under $H_{o}$ of a value as large as $X^{2}=12.84$ for 32 degrees of freedom is more than 0.99 , we do not reject $H_{o}$ and conclude that the differences amongst these indices may be due to sampling fluctuations.

[^2]ANNEXURE E
APPLICATION OF TWO-WAY ANALYSIS OF VARIANCE TEST TO AGGREGATE RECORD RELIABILITY INDICES FOR SAMPLE 'B' UNITS, IN EDUCATION DISTRICTS FOR SCHOOL YEARS 1970-71 TO 1974-75

| Year | 1970-71 |  | 1971-72 |  | 1972-73 |  | 1973-74 |  | 1974-75 |  | Mean |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| District | Obs. | Var. | Obs. | Var. | Obs. | Var. | Obs. | Var. | Obs. | Var. | Obs. | Var. |
| New Brunswick... | . 60 | . 19 | . 86 | . 07 | . 89 | . 10 | . 91 | . 12 | . 84 | . 05 | . 82 | . 03 |
| Montreal........ | . 81 | . 02 | . 83 | . 04 | . 84 | . 05 | . 83 | . 04 | . 86 | . 07 | . 83 | . 04 |

| Yorkton......... | . 71 | . 08 | . 74 | . 05 | . 75 | . 04 | . 67 | . 12 | . 68 | . 11 | . 71 | . 08 |
| Blood/Peigan.... | . 63 | . 16 | . 74 | . 05 | . 73 | . 06 | . 74 | . 05 | . 76 | . 03 | . 72 | . 07 |
| Nanaimo......... | . 83 | . 04 | . 89 | . 10 | . 87 | . 08 | . 89 | . 10 | . 90 | . 11 | . 88 | . 09 |
| North Coast. | . 82 | . 03 | . 82 | . 03 | . 82 | . 03 | . 85 | . 06 | . 92 | . 13 | . 85 | . 06 |
| Vancouver. | . 80 | . 01 | . 81 | . 02 | . 81 | . 02 | . 83 | . 04 | . 88 | . 09 | . 83 | . 04 |
| Mean. | . 73 | . 06 | . 79 | - | . 79 | - | . 80 | . 01 | . 84 | . 05 | . 79 | - |

Obs.: Observed value (Xij); Var.: Variation from grand mean (0.79).
Null Hypothesis (Ho): The Education Districts and School Years do not affect the aggregate record reliability indices.

Analysis of Variance a

| Source | Sum of Squares | d.f. | MSS | F-Ratio |
| :---: | :---: | :---: | :---: | :---: |
| Districts... <br> Years....... <br> Residual... |  | $\begin{gathered} I-1=8 \\ J-1=4 \\ (I-1)(J-1) 32 \end{gathered}$ | $\begin{gathered} 2.98 \\ 1.40 \\ 0.24 \end{gathered}$ | $\begin{gathered} 12.42 * * * \\ 5.83 * * * \\ - \end{gathered}$ |
| Total....... | $\sum_{i j} \sum_{j}\left(x^{i j}-x \ldots\right)^{2}=36.98$ | IJ-1=44 | - | - |

Since the probabilities associated with the occurrences under the $H_{0}$ of values as large as observed for F-ratio in the above table, namely 12.42 and 5.83 for degrees of freedom 8,32 and 4,32 respectively are less than $0.005 @$, we reject $H_{0}$ and conclude that the Education Districts and the School Years jointly affect the aggregate record reliability indices.

[^3]APPLICATION OF FRIEDMAN'S TWO-WAY ANALYSIS OF VARIANCE TEST TO RELIABILITY"INDICES FOR ALL ITEMS OF INFORMATION IN SAMPLE "B" UNITS FOR SCHOOL YEARS 1970-71 TO 1974-75.

| YEAR | $1970-71$ |  | $1971-72$ |  | $1972-73$ |  | $1973-74$ |  | 1974-75 |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ITEM OF INFORMATION | Index | Rank | Index | Rank | Index | Rank | Index | Rank | Index | Rank |
| 1. Home District | .84 | 1 | .86 | 2 | .87 | 3.5 | .87 | 3.5 | .89 | 5 |
| 2. Band Code | .83 | 1 | .86 | 2 | .87 | 3.5 | .87 | 3.5 | .90 | 5 |
| 3. Family Number | .84 | 1 | .86 | 2 | .87 | 3.5 | .87 | 3.5 | .90 | 5 |
| 4. Child Position | .84 | 1 | .86 | 2 | .87 | 3.5 | .87 | 3.5 | .90 | 5 |
| 5. Year of Birth | .84 | 1 | .86 | 2 | .87 | 3.5 | .87 | 3.5 | .90 | 5 |
| 6. Parent's Residence | .73 | 1 | .75 | 2 | .77 | 3 | .78 | 4 | .81 | 5 |
| 7. School Number | .61 | 1 | .72 | 2 | .74 | 3.5 | .74 | 3.5 | .81 | 5 |
| 8. Type of School | .56 | 1 | .64 | 2 | .68 | 3 | .69 | 4 | .79 | 5 |
| 9. Grade | .62 | 1 | .66 | 2 | .67 | 3 | .71 | 4 | .78 | 5 |
| 10. Day of Birth | .84 | 1 | .86 | 2.5 | .86 | 2.5 | .87 | 4 | .89 | 5 |
| 11. Month of Birth | .84 | 1 | .86 | 2 | .87 | 3.5 | .87 | 3.5 | .89 | 5 |
| 12. Type of Course | .74 | 2 | .78 | 4 | .79 | 5 | .77 | 3 | .73 | 1 |
| 13. Accommodation | .72 | 1 | .76 | 2 | .77 | 3 | .78 | 4 | .81 | 5 |
| 14. Allowance | .16 | 1 | .50 | 2 | .64 | 3 | .65 | 4 | .79 | 5 |
| 15. Language at Entry | .68 | 1 | .69 | 2 | .70 | 4 | .70 | 4 | .70 | 4 |
| 16. Surname | .92 | 1 | .93 | 2.5 | .94 | 4 | .93 | 2.5 | .95 | 5 |
| 17. Given Name (s) | .92 | 1.5 | .92 | 1.5 | .93 | 3.5 | .93 | 3.5 | .94 | 5 |

Null Hypothesis ( $H_{0}$ ): The school years do not have any effect on the item reliability indices.
$X_{r}^{2}=\frac{12}{N K(K+1)} \sum_{j=1}^{k}\left(R_{j}\right)^{2}-3 N(k+1)$ according to Friedman*
where $N=$ Number of rows $=17$
$\mathrm{K}=$ Number of columns $=5$

$$
R_{j}=\text { Rank Totals }=18.5,36.5,58.5,61.5,80.0 ;
$$

$$
\text { Therefore } \begin{aligned}
X_{T}^{2} & =\frac{12}{(17) \times(5) \times(6)}\left[(18.5)^{2}+\ldots+(80.0)^{2}\right]-(3) \times(17) \times(6) \\
& =1.1749
\end{aligned}
$$

Since the probability associated with the occurrence under $H_{o}$ of a value as large as 1.1749 for degrees of freedom $\mathrm{K}-1=4$ is between 0.80 and 0.90 * we do not reject $H_{o}$ and conclude that the differences in item reliability indices may be due to sampling fluctuations.

Tables
$3 \& 4$

Table 5

1. Population as of December 31, 1974 in the age group 10-14
(a) Off-Reserve. $\qquad$ (b) On-Reserve
905
2. Size of the sample selected for study
(a) Off-Reserve
9
(b) On-Reserve
150
3. Average number of ineffective sample units over the five school years under study
(a) Sample A:
(i) Both in the data bank and field
(ii) In the field only 0.8
(b) Sample B:
(i) Both in the data bank and field 25.2
(ii) In the field only 19.0
$\qquad$
4. Important reason(s) for loss of information:

Sample A: Unknown, No records.
Sample B: Unknown, No records, moved out.
5. Averaged percentage to the total number of student records belonging to criterion group EAN: (a) Sample A $78 \%$
(b) Sample B $68 \%$

EA
(a) Sample A $78 \%$
(b) Sample B $68 \%$

E
(a) Sample A $82 \%$
(b) Sample B $69 \%$
ean
(a) Sample A $18 \%$
(b) Sample B $31 \%$
6. Ranking of the Education District on the basis of average percentage . of student records satisfying criterion EAN
(a) Sample A $\qquad$ (b) Sample B $\qquad$
7. Record reliability indices for the Education District:
(a) Sample A:
(i) highest index $\qquad$ 0.98 in the school year 1974-1975
(ii) lowest index 0.67 in the school year 1973-1974
(b) Sample B: (i) highest index 0.81 in the school year 1974-1975
(ii) lowest index 0.57 in the school year 1971-1972

Table 6

Table 7

Table 8
8. Averaged percentages to the total number of sample units with the record reliability index of:
(a) one:
(i) Sample A $\qquad$ (ii) Sample B $\qquad$
(b) 0 to 0.04:
(i) Sample A $\qquad$ (ii) Sample B $\qquad$
(c) 0.50 to 0.54 :
(i) Sample A $\qquad$ (ii) Sample B $\qquad$
9. Median value of the aggregate record reliability index and ranking within the Education Districts:
(a) Median:
(i) Sample A $\qquad$ (ii) Sample B $\qquad$
(b) Rank:
(i) Sample A 3 (ii) Sample B $\qquad$
10. Item reliability indices averaged over all school years:
(a) Sample A: (i) highest index 89 for day and month of birth
(ii) lowest index 76 for grade, type of course, allowance
(iii) average over all essential items $\qquad$
80
(iv) ranking with other districts $\qquad$
(b) Sample B: (i) highest index 69 for year \& month of birth
(ii) lowest index_ 44 for allowances
(iii) average over all essential items 67
(iv) ranking with other districts $\qquad$
11. Comparison of indices by the three approaches:
(a) Sample A:
(i) highest index 1.00 by approach $\qquad$
in the school year 1974-1975
(ii) lowest index 0.67 by approach A, B, C
in the school. year 1973-1974
(iii) average difference among the three
approaches $\qquad$
(b) Sample B: (i) highest index 0.85 by approach ${ }^{\circ} \mathrm{A}$ in the school year $1974-1975$
(ii) Lowest index 0.57 by approach In the school year 1971-1972
(iii) average difference among the three approaches 0.036

Indices shown here are percentages of sample records identically reported in the data bank and field
records to the corresponding sample size.

Evaluation of the Data Bank based upon individual samples from Yorkton Education District

Table 1

Table 2

Tables $3 \& 4$

1. Population as of December 31,1974 in the age group 10-14
(a) Off-Reserve $\qquad$ (b) On-Reserve $\qquad$
2. Size of the sample selected for study
(a) Off-Reserve
24
(b) On-Reserve
94
3. Average number of ineffective sample units over the five school years under study
(a) Sample A:
(i) Both in the data bank and field $\qquad$
(ii) In the field only 3.2
(b) Sample B:
(i) Both in the data bank and field 14.8
(ii) In the field only 17.0
4. Important reason(s) for loss of information:

Sample A: Unknown, no records, moved out.
Sample B: No records, moved out.
5. Averaged percentage to the total number of student records belonging to criterion group EAN:
(a) Sample A $\quad 84 \%$
(b) Sample B $74 \%$

EA
(a) Sample A $84 \%$
(b) Sample B $75 \%$

E
(a) Sample A $\quad 84 \%$
(b) Sample B $76 \%$
ean
(a) Sample A $16 \%$
(b) Sample B
$24 \%$
6. Ranking of the Education District on the basis of average percentage . of student records satisfying criterion EAN
(a) Sample A $\qquad$ (b) Sample B $\qquad$
7. Record reliability indices for the Education District:
(a) Sample A:
(i) highest index 0.91 in the school year $197 \underline{0}-1971$
(ii) lowest index 0.78 in the school year 1973-1974
(b) Sample B: (i) highest index $\quad 0.75$ in the school year 1972 $\underline{\underline{L}}^{-197} \underline{\underline{2}}$
(ii) lowest index 0.67 in the school year 1973-1974

Table 6

Table 7

Table 8
8. Averaged percentages to the total number of sample units with the record reliability index of:
(a) one:
(i) Sample A
80\%
(ii) Sample B $32 \%$
(b) 0 to 0.04:
(i) Sample A $\qquad$ (ii) Sample B 24\%
(c) 0.50 to 0.54 :
(i) Sample A
Nil
(ii) Sample B $\qquad$
9. Median value of the aggregate record reliability index and ranking within the Education Districts:
(a) Median:
(i) Sample A $\qquad$ (ii) Sample B 0.92
(b) Rank:
(i) Sample A
81
(ii) Sample B
7
10. Item reliability indices averaged over all school years:
(a) Sample A: (i) highest index 84 for 13 of the 17 items
(ii) lowest index 81 for grade
(iii) average over all essential items 83
(iv) ranking with other districts 3
(b) Sample B: (i) highest index 76 for home, district, band, child position and type of course
(ii) lowest index 62 for Allowances
(iii) average over all essential items $\qquad$ 71
(iv) ranking with other districts
7.5
11. Comparison of indices by the three approaches:
(a) Sample A: (i) highest index 0.92 by approach A
in: the school year 1970-1971
(ii) lowest index 0.78 by approach $B$ and $C$
in the school year 1973-1974
(iii) average difference among the three
approaches
0.006
(b) Sample B: (i) highest index 0.82 by approach ${ }^{\circ} \mathrm{A}$
in the school year 1972-1973
(ii) Lowest index 0.67 by approach $B$ and $C$
in the school year $1973-1974$
(iii) average difference among the three
. approaches 0.052

TABLE 2.5
ANALYSIS OF INEFFECTIVE SAMPLE UNITS BY REMARKS CODE, TYPE, INDEX AND SCHOOL YEAR - YORKTON

Notes: 1. Index 'one' indicates total acceptance of computer printouts due to the absence of field-records.
2. Index 'zero' indicates total rejection of computer printouts due to the absence of field-records.

TABLE 3.5
FREQUENCY DISTRIBUTION OF SAMPLE UNITS BY CRITERION GROUP
BY TYPE BY SCHOOL YEAR - YORKTON

Sample A: No records, provincial authority.
Sample B: No records, moved out.
5. Averaged percentage to the total number of student records belonging to criterion group EAN: (a) Sample A 83\% (b) Sample B $93 \%$

| EA | (a) | Sample A | 83\% | (b) | Sample B | 93\% |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| E | (a) | Sample A | 83\% | (b) | Sample B | 93\% |
| ean | (a) | Sample A | 17\% | (b) | Sample B | 7\% |

6. Ranking of the Education District on the basis of average percentage of student records satisfying criterion EAN
(a) Sample A $\qquad$ (b) Sample B $\qquad$ 1
7. Record reliability indices for the Education District:
(a) Sample A:
(i) highest index 0.89 in the school year $1971-1972$
(ii) lowest index $\quad 0.77$ in the school year 1973-1974
(b) Sample B: (i) highest index 0.90 in the school year 1974-1975
(ii) lowest index 0.83 in the school year 1970-1971

Table 6

Table 7

Table 8
8. Averaged percentages to the total number of sample units with the record reliability index of:
(a) one:
(i) Sample A
$63 \%$
(ii) Sample B $36 \%$
(b) 0 to 0.04 :
(i) Sample A $\qquad$ (ii) Sample B $7 \%$
(c) 0.50 to 0.54 :
(i) Sample A $\qquad$ (ii) Sample B Nil
9. Median value of the aggregate record reliability index and ranking within the Education Districts:
(a) Median:
(i) Sample A $\qquad$ (ii) Sample B $\qquad$
(b) Rank:
(i) Sample A $\qquad$ (ii) Sample B $\qquad$
10. Item reliability indices averaged over all school years:
(a) Sample A: (i) highest index 83 for 10 of 17 items
(ii) lowest index 76 for Grade, Allowance
(iii) average over all essential items 82
(iv) ranking with other districts

4
(b) Sample B:
(i) highest index $\qquad$ 93 for 9 of 17 items
(ii) lowest index _67 for Allowance
(iii) average over all essential items $\qquad$
(iv) ranking with other districts $\qquad$
11. Comparison of indices by the three approaches:
(a) Sample A:
(i) highest index $\qquad$ by approach A and B
in: the school year $197_{1}-1972$
(ii) lowest index 0.77 by approach $B$ and C
in the school year 1973-1974
(iii) average difference among the three approaches $\qquad$
(b) Sample B: (i) highest index 0.95 by approach ${ }^{\circ} \mathrm{A}$
in the school year 1973-1974
(ii) Lowest index $\quad 0.83$ by approach B
in the school year 1970-1971
(iii) average difference among the three
, approaches $\quad 0.056$

Evaluation of the Data Bank based upon individual samples from Vancouver Education District

Table 5

1. Population as of December 31,1974 in the age group 10-14
(a) Off-Reserve $\qquad$ (b) On-Reserve $\qquad$ 892
2. Size of the sample selected for study
(a) Off-Reserve
22
(b) On-Reserve 149
$\qquad$
3. Average number of ineffective sample units over the five school years under study
(a) Sample A:
(i) Both in the data bank and field $\qquad$
(ii) In the field only 0.2
(b) Sample B:
(i) Both in the data bank and field 14.0
(ii) In the field only 0.8
4. Important reason(s) for loss of information:

Sample A: Study in U.S.A:, not registered, no records, moved out. $\qquad$

Sample B: Study in U.S.A., no records, $r$ moved out, provincial authority.
5. Averaged percentage to the total number of student records belonging to criterion group EAN:
(a) Sample A $\qquad$ (b) Sample B $\qquad$

EA
(a) Sample A $\qquad$ (b) Sample B $\qquad$
E (a) Sample A $83 \%$ (b) Sample B
ean (a) Sample A Nil (b) Sample B Nil
6. Ranking of the Education District on the basis of average percentage . of student records satisfying criterion EAN
(a) Sample A $\qquad$ (b) Sample B $\qquad$ 2
7. Record reliability indices for the Education District:
(a) Sample A: (i) highest index 0.78 in the school year 1974-1975
(ii) lowest index 0.55 in the school year 1971-1972
(b) Sample B: (i) highest index $\quad 0.88$ in the school year $1974 \underline{4} 1975$
(ii) lowest index $\quad 0.80$ in the school year 197 0-1971

Table 6

Table 7

Table 8
8. Averaged percentages to the total number of sample units with the record reliability index of:
(a) one:
(i) Sample A
$40 \%$
(ii) Sample B
$22 \%$
(b) 0 to 0.04 :
(i) Sample A
$17 \%$
(ii) Sample B $\qquad$
(c) 0.50 to 0.54 :
(i) Sample A $\qquad$ (ii) Sample B $\qquad$
9. Median value of the aggregate record reliability index and ranking within the Education Districts:
(a) Median:
(i) Sample A 0.6250
(ii) Sample B $\qquad$
(b) Rank:
(i) Sample A $\qquad$ (ii) Sample.B $\qquad$
10. Item reliability indices averaged over all school years:
(a) Sample A: (i) highest index 100 for given name
(ii) lowest index _ 44 for parents' residence, school number
(iii) average over all essential items 66
(iv) ranking with other districts $\qquad$
(b) Sample B: (i) highest index $\qquad$ 99 for name and surname
(ii) lowest index $\qquad$ for type of school
(iii) average over all essential items 81
(iv) ranking with other districts 6
11. Comparison of indices by the three approaches: 7
(a) Sample A:
(i) highest index $\qquad$ 0.91 by approach $\qquad$ A in: the school year $197 \underline{4} 1975$ and 1973-74.
(ii) lowest index 0.55 by approach $\qquad$ in the school. year 197_1972
(iii) average difference among the three approaches 0.17
(b) Sample B: (i) highest index 0.95 by approach •A
in the school year 1974-197 and 1973-74.
(ii) Lowest index $\quad 0.79$ by approach ___ C
in the school year 1970-1971 and 1971-72.
(iii) average difference among the three approaches 0.128

TABLE 2.9
analysis of ineffective sample units by remarks code, type, index and school year - vancouver

| Year | 1970-71 |  | 1971-72 |  | 1972-73 |  | 1973-74 |  | 1974-75 |  |
