No. 34, September 1973

**Report on 1972 sales of the Canada migratory game bird hunting permit, migratory game bird harvest and hunter activity**  
by F.G. Cooch,<sup>1</sup> G.W. Kaiser<sup>1</sup> and L. Wight<sup>1</sup>

**Introduction**

In 1972, geographical boundaries of survey substrata were unchanged from 1971 (see Appendix 1 of Progress Notes 28 and 9 for geographical co-ordinates). A major change was made in the method of sampling purchasers of Canada migratory game bird hunting permits, based on a sampling design developed by Dr. A.R. Sen and Dr. G.E.J. Smith, Biometrics Section. In addition the format of the survey questionnaire was changed to incorporate improvements in design developed by F. Filion, Biometrics Section.

All previously reported survey results were based on a sample drawn from the record of sales in the previous year. New hunters or those who do not hunt consistently from one year to the next were not sampled. In 1972 we were able to sample proportionally hunters with varying degrees of experience. At the same time the facility to produce data directly comparable to those of previous years was retained. For comparative purposes, therefore, this report contains kill statistics based on both the old and the revised survey methods. The effect of inclusion of the intermittent hunters will be obvious. More detail is given in the section relating to survey design.

**Permit sales**

The general rate of increase in the number of permits sold, slowed in 1972. As of January 31, 1973, 421,667 sales records had been placed on computer tape, an increase of only 3,440 over 1971. The 1972 sales record with comparable figures from 1969, 1970 and 1971 is given in Table 1. Of the 1972 total, 111,265 permittees are either new or inconsistent hunters with somewhat different characteristics from the remainder of the sample universe.

Table 2 is similar in design and intent to Table 2 of Progress Note 28 which gives permit sales by sample strata and province. The table also shows distribution of and response to the harvest survey questionnaire. Subsamples used in the 1972 sampling design have been lumped to give a single response rate. Consequently, it is no longer possible to extrapolate data from Table 2 except crudely.

As a result of permit redesign in 1972, only 22 of 421,667 permits could not be related to province and zone of sale. Consequently they are ignored, and for the first time no prorating of the sales record to zone or province of purchase was necessary.

A total of 25,851 questionnaires were mailed and delivered; 15,400 were returned (59.6 per cent), but of these 3,604 were unuseable because the respondents did not purchase a permit in 1972. The net response was therefore

<sup>1</sup> CWS, Ottawa, Ontario, K1A 0H3.

11,796 or 45.6 per cent, compared to 31.96 per cent in the 1971 survey. Characteristics of the subsamples and variations in response rate, and their implications for increased efficiency of the survey, are being studied independently of this report.

Table 2 shows potential hunters (permit purchasers), active hunters (those who hunted at least once) and successful hunters (those who harvested at least one bird) within each sample. Crude extrapolation factors to expand from the sample to the universe are derived by dividing the potential hunters from a zone (sampling strata) into the number of permits sold in that zone.

**The harvest survey**

The 1972 harvest survey sample was divided into four subsamples. Sample A was drawn from those who bought a permit in 1972 but not in 1971, sample B from those who purchased a permit in 1971 but not in 1970, and sample D from those who purchased permits in both 1970 and 1971 but had never been sampled. A fourth sample (C) was drawn from hunters who had responded in previous harvest surveys. This sample is not considered in the present report and is for research purposes only.

Results of the 1972 harvest survey by province are given in Table 3. The kill for any species is reported only from those areas where open seasons exist. For comparison, results of the 1971 harvest survey are given as well as results of the 1972 survey based on (a) subsamples B and D alone (this corresponds to last year's sampling method) and (b) subsamples A, B and D combined. Columns BD and ABD are also based on a reassignment of hunters to their indicated zone of hunting and not to their zone of purchase as in previous years. Successful hunters who moved out of the zone of purchase were deleted from further consideration within that zone but are included in the zone in which they hunted. Figures for 1971 have been adjusted in a similar manner.

Comparison of column ABD with BD shows the decrease from previous estimates of kill. This is due to inclusion of intermittent (new) purchasers of the permit in the sample. The changes in distribution of the kill are, we believe, a more accurate representation of the actual situation occurring in the field. These recalculations (inclusion of new hunters and assignment of data to actual zone of harvest) result in some major shifts in indicated kill and hunter activity between the zones in some provinces, but do not alter the provincial totals greatly.

In Table 3, the number of successful hunters is totalled for each species group but no attempt is made to provide a grand total of successful hunters for all groups combined because of the wide variety of species groups which may be taken by a single hunter. It is invalid to compute successful hunter totals based on Table 3 and compare them with totals given in Tables 4 and 5 under man-days of recreation.

## Survey results

If one includes intermittent hunters, national harvest totals for the major groups of migratory game birds changed little between 1971 and 1972. Gains in one province or zone were generally offset by decreases in others. If, on the other hand, estimates in 1972 had been based as in the past on a sampling universe derived from the sales record of the previous year, a harvest of 407,000 additional sport ducks would have been indicated. Except for woodcock and coots, kill of the minor species groups remained remarkably consistent with results published for 1971-72 (P.N. 28).

The full impact of the 1972 subsampling plan is not clearly shown in this report because nearly 8,000 American hunters were included in the 111,000 hunters who had not purchased a permit in 1972 (sample A). Many of these non-resident hunters may be specialists who go to areas of known good hunting, are experienced and successful, and give above average response to the survey. As a result of those characteristics, kill in zones of high concentration of non-resident hunters may be somewhat inflated. We are presently endeavouring to determine the degree of inflation and attempt ways of correcting that anomaly in the 1973-74 survey.

The new method of allocating hunters to zones does not have any effect on national totals but does result in varying degrees to reallocation among provinces and between sampling zones within provinces. The new procedure also

has an effect on the indicated average kill per successful and active hunter, as these are now also calculated on a zone of harvest basis weighted according to sampling fraction.

Average season bag per successful hunter or active hunter is a more useful statistic than total kill for assessing the quality of any given hunting season. Total kill is in part a function of permit sales, and may show an apparent increase which is not really related to improved hunting opportunity. In most zones there is greater difference between samples BD and ABD than there is between BD and the 1971 survey results. This is a result of the lower success rate of intermittent hunters.

An effort will be made to recalculate and publish material for previous progress notes of this series using this zone of harvest basis. It will not be possible to adjust previous harvest survey data to incorporate the effect of intermittent hunters.

Tables 4 and 5 give estimates of average daily bag, season bag and numbers of man-days of recreation spent hunting migratory game birds in 1972 for waterfowl and non-waterfowl. Because a hunter may hunt more than one species group it is not presently possible to add the two tables together and derive national totals of recreational activity. This has been a problem for several years, and a major redesign of the harvest survey questionnaire will be needed before the problem is solved.
