## Foreword

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the Secretariat.

#### Abstract

The 4X5Y Haddock Framework Assessment: Modeling and Reference Points meeting, held on April 26-27, 2016, was the second of two Maritimes Region of Fisheries and Oceans Canada peer review meetings for 4X5Y Haddock. This meeting was preceded by a 4X5Y Haddock 2014 Framework Assessment: Data inputs and Exploratory Modelling meeting, held on October 22, 2014. This research document summarizes the conclusions from the 'data inputs' meeting and describes the methodologies developed for estimating current stock status, fishery reference points, forecasting methodology for providing advice, guidance on inter-framework review activities and events that would trigger an earlier-than-scheduled assessment.

To resolve the retrospective pattern and other model fit issues observed in past 4X5Y Haddock stock assessments, Virtual Population Analysis (VPA) models with random walk in M (natural mortality) for different age groups were explored. A VPA model with M at Ages 10 and older fixed at 0.3, 0.6, and 0.9 for three 5 -year time blocks (2000-2004, 2005-2009, and 2010-2014; respectively) was recommended as the new framework model for the 4X5Y Haddock stock assessment. Despite the uncertainties in estimating $F_{\text {msy }}$, it was agreed at this framework meeting that an $F_{\text {ref }}$ of 0.25 would be a removal fishing mortality reference when the stock is in the Healthy Zone, and an F of 0.15 would be an appropriate target when the stock is in the Cautious Zone. Given that the poor stock recruit relationship precludes the calculation of an appropriate $B_{\text {msy }}$, a more conservative $B_{\text {recover }}$ (19,700 metric tonnes ( t ) was recommended as $\mathrm{B}_{\text {lim }}$ for 4X5Y Haddock.

# Évaluation du cadre de 2016 pour l'aiglefin de la division 4X5Y : Modélisation et points de référence 

#### Abstract

RÉSUMÉ La réunion sur l'évaluation du cadre pour l'aiglefin de la division 4X5Y : Modélisation et points de référence tenue les 26 et 27 avril 2016 a été la seconde de deux réunions d'examen par les pairs de Pêches et Océans Canada de la région des Maritimes organisées pour l'aiglefin de cette zone. Cette réunion a été précédée d'une réunion sur l'évaluation du cadre de 2014 pour l'aiglefin de la division 4X5Y: Saisie de données et modélisation exploratoire, tenue le 22 octobre 2014. Le présent document de recherche résume les conclusions de la réunion sur la « saisie de données » et décrit les méthodes mises au point pour estimer l'état des stocks actuels et les points de référence des pêches, et fournir les prévisions qui guident les activités de l'examen intercadres et les événements qui peuvent nécessiter une évaluation plus tôt que prévu. Afin de résoudre les problèmes observés lors des évaluations du stock d'aiglefin de la division $4 X 5 Y$ réalisées par le passé (problèmes avec la tendance rétrospective et l'intégration des autres modèles), on a examiné des modèles d'analyse de la population virtuelle (APV) comportant une marche aléatoire du M (mortalité naturelle) pour différents groupes d'âge. Comme nouveau modèle de cadre pour l'évaluation du stock d'aiglefin de la division 4X5Y, on a recommandé un modèle d'APV avec une valeur M de 10 ans et plus fixée à 0,$3 ; 0,6$, et 0,9 pour trois blocs de cinq ans (2000-2004, 2005-2009 et 2010-2014, respectivement). Malgré les incertitudes sur le plan de l'estimation de la valeur $\mathrm{F}_{\mathrm{rms}}$, on a convenu à cette réunion sur le cadre que la valeur de référence pour la mortalité par capture serait un $F_{\text {réf }}$ de 0,25 lorsque le stock se situe dans la zone saine, et qu'une valeur $F$ de 0,15 serait une cible adéquate lorsque le stock se situe dans la zone de prudence. Étant donné que la faible corrélation entre stock et recrutement empêche de calculer un $B_{r m s}$ approprié, on a recommandé un $B_{\text {rétablissement }}$ plus conservateur (19 700 tonnes métriques [ t ) comme $\mathrm{B}_{\text {lim }}$ pour l'aiglefin de la division 4X5Y.

## INTRODUCTION

Haddock (Melanogrammus aeglefinus) are found on both sides of the North Atlantic and occur in the northwestern Atlantic from southwest Greenland to Cape Hatteras. A major stock exists on the western Scotian Shelf and in the Bay of Fundy (Northwest Atlantic Fisheries Organization (NAFO) Divisions 4X5Y) (Figure 1). Growth rates of Haddock in the Bay of Fundy (4Xqrs5Y), are higher than those of Haddock on the western Scotian Shelf (4Xmnop) (Hurley et al. 1998) so separate age length keys (ALKs) have been used in the past for calculating the fishery catch at age (CAA) and survey indices of abundance. Major spawning grounds are found on Browns Bank and peak spawning occurs from April to May, although it can occur as early as February if conditions are favourable (Head et al. 2005). A seasonal spawning closure, implemented in 1970, currently extends from February $1^{\text {st }}$ June $15^{\text {th }}$ (Halliday 1988).

NAFO Divs. 4X5Y Haddock are harvested as part of a mixed, multi-species fishery that includes Atlantic Cod, Atlantic Halibut, redfish, Pollock, White Hake, and flounders. The Haddock fishery is limited by the incidental catch of Cod which has strict bycatch limits. The mandatory use of a 130 mm square mesh Cod end for bottom trawl was implemented in 1991 to allow for escapement of smaller fish; however, Haddock are also captured as bycatch in the redfish fishery, which uses smaller 100-112 mm diamond mesh Cod ends.

In past assessments, the 4X5Y Haddock stock has been modelled using Sequential Population Analysis (SPA) tuned to two surveys: the Fisheries and Oceans Canada (DFO) Summer Multispecies Ecosystem survey (1970 to present) and a joint Industry/DFO survey (Individual Transfer Quota (ITQ) survey) (Showell et al. 2013), with the latter discontinued after 2012. The fishery has been managed using a removal reference ( $\mathrm{F}_{\text {ref }}=0.25$ ). A limit reference point (LRP) of $40 \%$ SSB $_{\text {MSY }}\left(20,800\right.$ metric tonnes(t)) and upper stock reference point (USR) of $80 \%$ SSB $_{\text {MSY }}$ $(41,600 \mathrm{t})$ based on estimates from a Sissenwine-Sheppard stock production model (Mohn et al. 2010) have been calculated as illustrative biological reference points for this stock.

The last analytical assessment conducted in 2012 (Showell et al. 2013) suggested that Age 4+ biomass (a proxy for spawning stock biomass (SSB)) has remained relatively stable over the past two decades and is likely within the Cautious Zone. However, a strong retrospective pattern in the model results (i.e. a tendency to overestimate Age 4+ biomass and underestimate Ages 6-9 F when additional years of data were added), and a miss-match between survey and catch information, indicated that the recent increases in Age 4+ biomass were likely overestimates (Figure 2). Consequently, the SPA model results were not considered sufficiently reliable to produce meaningful projections for 2013 and 2014. A framework review for the 4X5Y Haddock assessment was recommended, given the continuing strong retrospective pattern in the model and its poor fit to the survey indices.

## FRAMEWORK REVIEW PROCESS

In 2014, the Maritimes Region of DFO initiated a 2-part framework assessment review of 4X5Y Haddock. The first part focused on commercial fishery and survey data inputs, which were evaluated during a meeting conducted at the Bedford Institute of Oceanography in Dartmouth, NS, on October 22, 2014, and documented in Stone and Hansen (2015). The main elements of the data inputs review included:

- Stock Structure.
- Fishery spatial and temporal distribution, bycatch, CAA, weight at age (WAA), length at age (LAA), maturity, growth and the appropriateness of using area-specific age-length keys (Bay of Fundy, Scotian Shelf).
- Research Vessel survey age-specific indices of abundance, weight/length at age, maturity, growth, condition and age-specific spatial distribution.
- Exploratory Virtual Population Analysis (VPA) runs to evaluate the influence of input data revisions (i.e. exclusion of the ITQ index, revised ageing for 1985-1989, use of 2 cm groupings, inclusion of a small mesh category), truncating the CAA time series (i.e. 19852013 vs. 1970-2013), and the effects of removing mixed stock (i.e. 5Zjm and 4X5Y) Haddock catches near the 4X5Y NAFO boundary line.

The main conclusions from the data input review (also summarized in Stone and Hansen 2015) are provided below.

## Commercial Fishery

- The current 4X5Y Management Area is appropriate for this stock; there is no new information to indicate otherwise.
- Landings have been less than 4,000 t (below the Total Allowable Catch, TAC) since 2012, and have been taken mainly by small otter trawlers (Tonnage Class (TC) 1-3, 80\%), followed by longline (20\%). The share taken by longline has declined since 2011.
- Most landings currently come from Scotian Shelf statistical Unit Areas 4Xn and 4Xp during the $1^{\text {st }}$ and $3^{\text {rd }}$ quarters; a general seasonal/geographic pattern in areas fished has evolved to reduce Cod bycatch.
- Haddock landings from the mixed stock area in $4 \times p$ south (i.e. within 5 nautical miles north of the 4 X5Z NAFO Area line) were as high as $1,350 t$ and 2,400 $t$ in 2005 and 2007, respectively, but have declined to low levels in recent years.
- Past occurrences of high catches in $4 X$ p south may reflect periods when above average year classes from the eastern Georges Bank stock (i.e. 2000, 2003) expanded into the Fundian Channel and were captured in 4Xp during the summer/fall fishery.

## Fishery Catch at Age (CAA), Weight at Age (WAA), and Length at Age (LAA)

- The CAA time series was re-calculated using 2 cm groupings for 1985-2010 and revised age determinations for 1985-1989, and it is now considered to be more consistent in terms of the approach used.
- Revised fishery WAA did not have the precipitous drop in WAA values for Ages 9 and 11, which occurred in the old series from 1987-1988; the revised series continues to show a declining trend from 2000-2008, then levels off.

## DFO Summer Survey

- Survey indices, WAA and LAA were recalculated for Scotian Shelf (470-481) and Bay of Fundy Strata (482-495) and then combined.
- The main areas of Haddock abundance were on Browns, Baccaro and LaHave banks; there was an increase in biomass in the Bay of Fundy in the 1980s and 1990s followed by a decline in the 2000s.
- There has been a decline in survey WAA for Ages 5 and older beginning in the early 1980s, similar to the trend in fishery WAA. Current stock productivity is lower now compared to the past.
- Von Bertalanffy growth model parameters indicate that Haddock from Bay of Fundy Strata grow faster and attain a larger size than Haddock from Scotian Shelf Strata.
- There has been a temporal shift in the size at $50 \%$ mature for both sexes such that fish are currently maturing at smaller sizes in the recent period (2011-2014) compared to the early part of the time series (1979-1986). Haddock Age 4+ will continue to be used as a proxy for spawning stock biomass.
- Fulton's K has been declining since 1990; more rapidly for Bay of Fundy Haddock.
- There has been an improvement in age structure since the late 1990s (increase in Age 6+).
- Indications from 2013 and 2014 surveys are that the 2013 year class is the strongest in the 44 year time series.

## Observer Coverage and Bycatch

- Observer coverage for directed Haddock trips over the past 10 years has averaged approximately $4 \%$ for mobile gear and approximately $2 \%$ for fixed gear, too low for estimating bycatch rates.
- Discard estimates are low in Haddock directed and non-directed fisheries; dogfish, Lobster, and skates are the primary discarded species.

## Exploratory Virtual Population Analysis (VPA) Model Comparisons

- Removing the ITQ Survey series as a tuning index had a small influence on estimates of Age 1 recruitment, Age 4+ biomass and Ages 6-9 fishing mortality for the recent period up to 2010. The ITQ Survey has been discontinued as of 2013 and will not be used as a tuning index in future modelling.
- Revisions to the CAA up to 2010 resulted in only minor changes to past estimates of $4+B$ and 6-9F. The revised CAA has been calculated using a more consistent approach than the previous CAA.
- Removing early years from the CAA time series (1970-1984), which were not re-aged using revised ageing criteria, had no impact on model results. The proposed time series for input data (i.e. fishery and survey CAA, WAA) used for framework modelling will start from 1985.
- VPA analysis using data inputs extended to 2013 illustrated the persistence of the retrospective issue. The various data revisions were not enough to alleviate the retrospective problem and there are other issues with the VPA model that need to be resolved.
- Removing catches and port sample length frequencies (LF)/ages from 4Xp South, an area where 5Zjm and 4X5Y stocks may overlap, particularly when there are strong year classes in $5 Z$, had little effect on estimates of $R, 4+B$, and $6-9 \mathrm{~F}$ and will not be considered for further analysis.
- Allowing the model to estimate natural mortality (M) on Ages 8+ from 1995 to present indicated that M had increased on older fish in the recent period. Using higher M in the VPA model may help to reduce the retrospective pattern. Further exploration of models that use higher M (i.e. Random Walk M ) is recommended.
The second part of the framework review process took place at the Biological Station in St. Andrews, NB, from April 26-27, 2016, and focused on the model(s) used to determine stock
status, reference points, risk analysis and the inter-framework assessment strategy. The primary elements of this review include:
- Determining the methodology to estimate the current status of the stock, including methods for estimating stock size and fishing mortality.
- Determining the methodology to characterize stock productivity including reference points for fishing mortality and spawning stock biomass.
- Determining the forecasting methodology for providing advice on harvest levels including the risk of falling below biological reference points.
- Providing guidance on inter-framework review activities, including the procedure and frequency of providing fisheries management advice and events that would trigger an earlier-than-scheduled assessment.

This research document provides an overview of the framework methodology used to provide future assessments of stock status.

## FISHERY UPDATE

## Commercial Landings

Reported annual landings of 4X5Y Haddock averaged18,500 t during the 1970s and 19,800 t during the 1980s with peaks occurring in the late 1960s and early 1980s (Table 1; Figure 3). Noteworthy is that from 1982-1984, the TAC peaked at 32,000 t , but was quickly reduced to $4,600 \mathrm{t}$ by 1989. In 1991 and 1992, there was no TAC for Haddock under a Management Plan that called for a bycatch fishery only, although landings exceeded 9,000 t during these years (Hurley et al. 2009). The TAC of $8,100 \mathrm{t}$ established for the 12-month fishery in 1999 was extended to $9,800 t$ for the 15 -month period ending March 31, 2000. The fishing year since then has been April $1^{\text {st }}$ to March $31^{\text {st }}$. Annual landings dropped substantially in the 1990 s and 2000s, averaging 6,681 t and 4,260 t, respectively. Since 2010, landings have been below 5,000 t and in 2014 and 2015 they were 2,718 t and 2,789 t,respectively, the lowest in the 40 year time series. The Fishing Year (FY) TAC (FY, April $1^{\text {st }}-$ March $31^{\text {st }}$ ) was $7,000 \mathrm{t}$ from 2006-2009, but was subsequently reduced to 6,000 t for FYs 2010/2011 and 2011/2012 and to 5,100 t for FYs 2012/2013 through 2015/2016 (Table 1). Fishing year landings for 2014/2015 and 2015/2016 were $2,825 \mathrm{t}$ and $2,964 \mathrm{t}$, respectively, well below the TAC.

Since the mid-1970s, the small mobile gear component (bottom trawl, TC 1-3) has accounted for most of the total landings, with the exception of the early 1990s when the percentage taken by fixed gear (longline) was greater (Figure 4; Table 2). The percentage of landings from longline has steadily declined since 1994, whereas the small mobile gear share has increased. Over the past 10 years, small otter trawlers (TC 1-3) have taken an average of about $80 \%$ of the catch and longline vessels about 20\%. There has been a declining trend in longline catches since 2011, with the 2015 catch representing only $4 \%$ of total landings (compared to $96 \%$ for mobile gear). Large otter trawlers (TC 4+) contributed 30-40\% of total landings in the 1970s but there are few left in the fishery at present (their contribution is currently < 1\%). The contribution by the handline and gillnet sectors has also declined to very low levels ( $<1 \%$ ) since the late 1990s.

Since 2010, most landings have occurred during the $1^{\text {st }}$ quarter (44\%), followed by the $3^{\text {rd }}(24 \%), 4^{\text {th }}(19 \%)$ and $2^{\text {nd }}(13 \%)$ quarters (Table 3). The change to an April-March fishing year in 2000 has led to an increase in the proportion of fish landed during January to March, a seasonal change that has helped to reduce the bycatch of Cod (Hurley et al. 2009). This is also when the Georges Bank fishery for Haddock is closed (i.e. mid-February to May 31 ${ }^{\text {st }}$ ), so there
is likely a shift to fishing the $4 \times 5 Y$ stock at this time of year. Over the past decade, about $75 \%$ of total landings have been taken from Scotian Shelf Statistical Unit Areas 4Xn and 4Xp (Figure 5). While the increase in 4 Xn is largely a result of the winter (January-March) fishery, the increase in $4 X p$ reflects directing for larger Haddock in the deeper waters of the Fundian Channel where the bycatch of Cod also tends to be lower (Hurley et al. 2009).
Most of the 4X5Y Haddock fishery catch is currently taken on the Scotian Shelf (4Xmnop) by the mobile gear sector followed by fixed gear, with the remainder taken in the Bay of Fundy (4Xqrs5Y) by mobile gear (Table 4; Figure 6). Fixed gear catches from the Bay of Fundy region (4Xqrs5Y) are now very low and there has been an overall decline in catches from this area by both gear sectors since 2005 (Figure 7).
Showell et al. (2013) reported that the distribution of the fishery has changed in the last decade with effort shifting from the Bay of Fundy to Statistical Unit Area 4Xp, which, over the past 10 years, is where about 43\% of the total Haddock catches have occurred. Noteworthy is that in 2004, 2005, 2007 and 2009, 14-35\% of total annual landings occurred in the southern portion of $4 \times p$ in the Fundian Channel close to the 4X5Z NAFO boundary line (Figure 8). Showell et al. (2013) hypothesized that these fish may be from the eastern Georges Bank (5Zjm) stock, rather than 4X5Y. Stone and Hansen (2015) examined the impact or removing catches and port sample length frequencies/ages from VPA model input data and showed that there was little or no effect on model results (i.e. estimates of Age 4+ biomass, Age 1 recruits and Age 6-9 fishing mortality) when this data was excluded, therefore, it is included in the CAA time series.

## Fishery Catch at Age and Length/Weight at Age

The 4X5Y Haddock fishery CAA, WAA and LAA was updated for 2011-2014 and revised for 1985-2010 (see Stone and Hansen 2015 for revision history). For CAA calculations, the length frequencies obtained by port samplers were grouped by Gear (Mobile, Fixed), Season (QTR or Half Year) and Area (Bay of Fundy: 4Xqrs5Y; Scotian Shelf: 4Xmnop). Age length keys were grouped by Area and Season (Qtr or Half Year). Annual length-weight relationships (a's and b's) for Haddock from the DFO Summer survey were calculated separately for Bay of Fundy Strata (482-495) and Scotian Shelf Strata (470-481) and applied to matching sample areas for CAA determinations.

Catch at Age calculations for 2011, 2012 and 2013 included a separate category for Haddock catches from the 4X redfish fishery, which uses a smaller Cod end mesh size (i.e. 100-112 mm diamond mesh) and has a tendency to retain more small fish (i.e. Ages 2-3). Haddock catches from the 4 X redfish fishery increased from $<1 \%$ of total landings in the early 1990s to $8 \%$ by 2002, declined to <2\% in 2003-2004, then increased steadily reaching $15 \%$ in 2012 and $13 \%$ in 2013 before dropping off to $6 \%$ in 2014 (Figure 9). For 2011-2014, small mesh gear landings of Haddock were 325 t , 623 t , 460 t , and 128 t , respectively. With the exception of 2011-2013, there were too few port samples available to size the small mesh catches in CAA calculations from earlier years and for 2014.
The revised 4X5Y Haddock fishery CAA data for framework modelling includes Ages 1-14 for 1985-2014 (Table 5; Figure 10). This series shows the presence of some recent strong year classes (i.e. 2003,2010) and a reduction in the catches of Age 2 fish beginning in the early 1990s. The latter coincides with the mandatory use of 130 mm square mesh in 1991, but also there has been a decline in WAA and LAA during this period, which has reduced the partial recruitment/selectivity of this age group (Table 6; Figure 11 and 12). In the 2014 fishery, the 2010 year class at Age 4 (the most recent strong year class) was predominant and represented $42 \%$ of the CAA followed by the 2011 year class at $21 \%$. The 2003 year class, which made a significant contribution to the fishery back to 2006, represented only $1 \%$ of the 2014 fishery
catch at Age 11. Noteworthy is that older fish (Age 10+) continue to appear in the time series right up to 2014.
There have been significant changes in the catch at size by gear type (mobile vs. fixed) and area (Bay of Fundy vs. Scotian Shelf) over the 30 year time period (1985-2014), which could contribute to changes in selectivity and partial recruitment to the fishery (Figure 13). Not only are Haddock captured in the recent period (2010-2014) considerably smaller than they were in the past, but the contribution from the fixed gear sector, which generally captured larger fish than mobile gear, has greatly diminished, especially from the Bay of Fundy. Catches by mobile gear from the Bay of Fundy have declined as well, so that the fishery is now largely conducted on the Scotian Shelf by this sector.

A revised time series of fishery mean weights at age (WAA, kg) and lengths at age (LAA, cm) for 1985-2014 was calculated from the catch at age application (Table 6; Figure 11 and 12). The weighting of WAA is done internally in the CAA workspace. Separate ALK's are used for Scotian Shelf and Bay of Fundy samples to generate numbers at age (NAA), which are then used for weighting the calculations of the overall fishery WAA. Both series indicate a declining trend in WAA and LAA from the early 1990s to mid-2000s and then either show a modest increase or leveling off in the recent period. While it is not clear what caused the declining trend over this time period, the effect on stock productivity is significant and has been discussed in previous assessments (Hurley et al. 2009; Mohn et al. 2010).

## DFO SUMMER RESEARCH VESSEL (RV) SURVEY UPDATE

## Catch Distribution, Indices of Abundance, Length/Weight at Age

DFO has conducted a stratified random bottom trawl survey of the Scotian Shelf and Bay of Fundy every summer since 1970. Over the 45-year DFO Summer survey time series (19702015), the main areas of Haddock abundance have been on Browns Bank, Baccaro Bank and the outer Bay of Fundy area. In the 1980s and 1990s, there was an increase in biomass in the Bay of Fundy, followed by decline in the 2000s that persists to 2015 (Figure 14).
Due to differences in growth rates (Hurley et al. 1998), the total biomass index is calculated separately for the Bay of Fundy (Strata 482-495) and western Scotian Shelf (Strata 470-481) for 1970-2015 (Figure 15). While both indices show high variability over the time series, the general pattern is one of decreasing biomass from the mid-1980s to mid-1990s, followed by a period of increasing biomass through the late 1990s to the early 2000s, lower biomass from 2004-2013, after which it increases (Table 7; Figure 16). The total biomass index has been below the long term mean for the western Scotian Shelf since 2011 and for the Bay of Fundy since 2003. Scotian Shelf Strata have accounted for approximately $64 \%$ of total biomass since 2006. In 2015, the total biomass estimate for the Bay of Fundy was 32,200 t (1970-2015 mean: $21,800 \mathrm{t}$ ) and for the Scotian Shelf it was $37,600 \mathrm{t}$ (1970-2015 mean: 33,500 t). The total biomass index in 2015 for both areas combined was $70,000 \mathrm{t}$.

The age-specific indices of abundance (total numbers at age) for 1970-2014 were calculated separately for Bay of Fundy Strata (482-495) and western Scotian Shelf Strata (470-481) and then combined to generate the indices of abundance for the entire 4 X 5 Y management area (Strata 470-495) (Table 8). Since the early portion of the series was not re-aged, only data from 1985-2014 will be used as a tuning index in VPA modelling (Figure 17). During the late 1980s, there was a period of diminished numbers at age for all ages that persisted until the early 1990s. The abundance at age increased from 1995-2002, especially for Ages 1-5, and was followed by an overall improvement in age structure, with increased abundance of Ages 6+ up to about 2011. The 2003, 2006, and 2010 year classes all appear to have been moderately
strong, with indications that the 2013 year class (Age 1 in 2014) is the strongest in the time series. In 2014, Ages 1-4 made up most of the survey catch (the 2013, 2012, 2011, and 2010 year classes) and represented $77 \%, 7 \%, 6 \%$, and $6 \%$ of the survey CAA, respectively.
DFO Summer survey mean weight at age (WAA, kg) and mean length at age (LAA, cm) for 4X5Y Haddock was calculated separately for Bay of Fundy and western Scotian Shelf Strata, then combined after weighting using total abundance at age for each area (Tables 9 and 10). The revised survey WAA time series for 1985-2014 is used for calculations of beginning of year biomass after applying the Rivard back-calculation method. Similar to the trends observed for the commercial fishery, the DFO Summer survey values for mean WAA and LAA show a decline from the early 1990s to the mid-2000s then level off or show a modest increase (Tables 9 and 10; Figures 18 and 19).

A comparison of 4 X 5 Y Haddock mean WAA for Ages 3, 5, 7, and 9 from the commercial fishery and the DFO Summer survey indicates a higher mean weight at Age 3 in the fishery compared to the survey, with diminishing differences as age increases (Figure 20). Beginning of year and projected Age 4+ (spawning stock) biomass calculations use DFO Summer survey WAA values, while projected catch yields are based on fishery WAA.

## DATA FEATURES THAT MODELS NEED TO FIT/EXPLAIN

## FISHERY AND SURVEY CATCH AT AGE

The Coefficient of Variation (CVs) values for 1985-2014 Bay of Fundy and Scotian Shelf combined fishery catch at age are shown in Table 11. CVs were generally less than $30 \%$ for the younger ages (1-10). There was considerable uncertainty in the estimates of catch at age among some of the older ages (11-16). Considering the small contribution of the older age groups (11-16) to the total fishery catch (ranged from $0.2 \%$ to $6.1 \%$ by number, $1 \%$ to $8 \%$ by weight), an age-aggregated 11+ group was used in the model input (Table 5).
The DFO Summer survey catch at age CVs are shown in Table 12. The average CVs were below 30\% for Ages 2-10. Considering the higher CVs and zero observations in the older age groups, the survey catch at age 1-10 was used as abundance indices (Table 8).

## FISHERY SELECTIVITY CHANGES

The spatial distribution of the 4X5Y Haddock fishery has changed in the last decade with effort shifting from the Bay of Fundy to the western Scotian Shelf. Most landings currently come from Scotian Shelf Unit Areas 4Xn and 4Xp (Figure 5). The change to an April-March fishing year in 2000 resulted in an increase in the proportion of fish landed during January to March. The proportion of the landings from mobile and fixed gear has also changed since the mid-1990s with fixed gear catches currently representing $<10 \%$ of total landings (Figure 4). A reduced price for Haddock and the inability to avoid Cod bycatch has likely contributed to the decline in catches from the longline gear sector. Changes in the geographic and seasonal distribution of the fishery as well as in the proportion of catch by gear type have likely affected fishery selectivity over time (Figure 13). The length and age composition of Haddock show differences between gear sectors, with more older, larger fish captured by longline compared to mobile gear (Figures 19-21; Stone and Hansen 2015); however, the contribution from fixed gear has greatly declined in recent years.

Clark (2014) proposed a method to calculate the ratio of selectivity of two fisheries or surveys at each age or length directly from the age or length composition data. This method calculated a relative value of fishery selectivity and survey selectivity. Under the assumption of no temporal
changes in survey selectivity, these values could be used to detect temporal changes of fishery selectivity relative to the survey. Results using data from the fishery and RV survey CAA from 1985-2013 indicated a flat relative fishery selectivity for the post-1994 period, while the selectivity on older fish (10+) in the pre-1994 period was double that for post-1994 (Figure 1). This information in a model independent framework was used to understand the possible fishery partial recruitment (PR) changes (dome- or flat-shaped PR) and to help determine future model setup.

## RELATIVE F AND SURVEY Z

Total mortality (Z) at age was calculated from the DFO Summer survey catch at age. Relative fishing mortality at age (Relative F) was calculated as the ratio of fishery catch at age over the survey catch at age (Figure 22). Relative $F$ has generally declined on younger ages (2-7) in the mid-1990s and again after 2000 for the older ages (8+). However, survey Z on Ages 10+ has not declined and has remained high throughout the time series.

Catch curve analyses were conducted on log-transformed relative abundance data from a cohort in successive years, which removed the confounding effects of differential year class strength on the interpretation of catch curve results. Using Age 5 as the fully recruited age, Figure 23 shows survey Z for Ages 5-9 and Ages 10-14 and Relative F from a cohort in successive years for the same age groups. Relative F on both age groups dropped significantly around the mid-1990s, while $Z$ on the older age groups (10-14) has stayed at even higher levels.

Discarding and high-grading of Haddock appeared to be negligible (Hurley et al. 2009) because catches have been lower than the TAC since 2005. Based on the above analysis, there may be factors other than the fishery contributing to population dynamics.

## POPULATION MODEL: VIRTUAL POPULATION ANALYSIS (VPA) WITH RANDOM WALK IN NATURAL MORTALITY (M)

In order to address retrospective patterns and other data and model fit issues, a VPA model with time-varying natural mortality (M) was fit to 4X5Y Haddock data. This model was used to determine when M increased (in time) and which age groups were affected. Simulation tests of these VPA models for eastern Georges Bank and southern Gulf of St. Lawrence Cod indicated that they resulted in reliable conclusions about changes in M (Swain 2013, Swain and Benoit 2015).

For 4X5Y Haddock, the data inputs to this model were fishery catch at age for Ages 1-11+ (1985-2014) and DFO Summer survey swept area abundance indices for Ages 1-10 (19852014). Zero observations for abundance indices were treated as missing data. In this model, independent time series of $M$ were modelled as a random walk for different age groups,

$$
\begin{gather*}
M_{j, 1985}=\text { Minit }_{j}  \tag{1}\\
M_{j, y}=M_{j, y-1} e^{M d e v_{j, y}} \text { if } \mathrm{y}>1985 \tag{2}
\end{gather*}
$$

where $j$ is the age group, $y$ is the year. Minit $j_{j}$ is the $M$ for age group $j$ at first year (1985).
Based on the analysis for possible fishery selectivity changes, $F$ on the Age 11+ group ( $F_{11+}$ ) was assumed equal to 2 times $F$ on Age $10\left(F_{10}\right)$ for 1985-1994, and $F_{11+}$ was set equal to $F_{10}$ for 1995-2013. Minit $j_{j}$ Mdev $_{j, y}$, survey catchability at age, and terminal year (2015) population
abundance at age were the model parameters. These parameters were estimated by minimizing an objective function with the following components:

1. a component for the discrepancy between observed and predicted values of the abundance indices at age, which were assumed to be log-normally distributed;
2. a penalty for departures of Minit from its prior value (normal priors for Minit $j_{j}$ were set at mean of 0.2 and a standard deviation of 0.05 for all the age groups); and
3. a penalty for departures of $M d e v_{j, y}$ from its prior value. A normal prior for $M d e v_{j, y}$ was set at a mean of 0 and a standard deviation of 0.05. For model details, see Swain (2013).
Three models with trends in $M$ were estimated separately for different age groups:
A. 2 M age groups: 1-3 and 4+;
B. 3 M age groups: 1-3, 4-6, and 7+;
C. 4 M age groups: 1-3, 4-6, 7-9, and 10+.

The results from the three model runs suggested:
A. Estimated $M$ for Ages 1-3 was about 0.2, but estimated $M$ for Ages $4+$ started to increase from 2000 and stayed at a higher level of 0.4 from 2005 onwards.
B. Both the estimated $M$ for Ages 1-3 and 4-6 were around 0.2 with no significant trend, but M for older Ages 7+ showed a clear increase from 2000 and stayed at a higher level of 0.6 from 2005 onwards.
C. Estimated M for the 3 younger age groups 1-3, 4-6, and 7-9 were relatively stable and stayed around 0.2 , but M for older Ages $10+$ were greater and estimated as about 0.27 in the early years, then increased since 2000 and reached a higher level of 0.8 in most recent years (Figure 24).
There was no obvious temporal pattern in the residuals from model C (Figure 25); however, some cohort patterns exist. There was still a retrospective pattern for SSB (4+) and F (Figure 26), but it was greatly improved compared with the past model retrospective and residual patterns (Figures 2 and 27).

## POPULATION MODEL: VPA WITH M IN AGE AND TIME BLOCKS

The adaptive framework, ADAPT (Gavaris 1988), was used for calibrating VPA with the trends in abundance from the DFO Summer survey. The model input data was the same as the random walk of $M$ models. Fishing mortality on the plus group (F11+) was set up using the $\mathrm{F}_{\text {ratio }}$ method in ADAPT. Based on the results from the random walk of $M$ model, $M$ was fixed at 0.2 for all the ages and years except for the Ages 10-11+ after 2000. The M for Ages 10-11+ was estimated by three 5 -year time blocks beginning in 2000. The three time blocks were for years 2000-2004, 2005-2009, and 2010-2014. Other model parameters included survey catchability at age for Ages 1-10 and terminal year population abundance at age for Ages 2-11+. All the parameters were estimated by minimization of the discrepancy between observed and predicted values of the abundance indices at age, which were assumed to be log-normally distributed. Statistical properties of the estimators were determined using conditional non-parametric bootstrapping of model residuals (Rivard and Gavaris 2003).
Natural mortality was estimated as 0.26 with CV of $30 \%, 0.62$ with CV of $8 \%$, and 0.9 with CV of $8 \%$ for years 2000-2004, 2005-2009, and 2010-2014, respectively. Based on the above analysis, a VPA model with M fixed at $0.3,0.6$, and 0.9 for Ages $10-11+$ for the three 5 -year time blocks (2000-2004, 2005-2009, and 2010-2014) was recommended as the framework
model for 4X5Y Haddock. The model residuals (Figure 28) have similar patterns to the random walk M model. Some of the stronger cohorts at younger ages were underestimated by the model. Survey catchability started at 0.5 for Age 1 and gradually increased to around 1.0 at the fully recruited Age 4 with a relatively flat topped selectivity for the older ages (Figure 29). The retrospective analysis still showed some minor retrospective patterns. For the most recent 3 years, the model tended to overestimate the biomass and underestimate $F$ when each year of data was peeled off (Figure 30).

The calculated F (population number weighted average over Ages 6-10) is shown in Figure 31 and Table 13. The model results showed high fishing mortality early in the time series until about 1998, after which fishing mortality remained low, and was estimated at 0.08 in 2014. Spawning stock biomass (4+) decreased from 42,000 tin 1985 to 20,000 tin 1990, and started to increase in 1996 due to the contribution of the strong cohorts of 1993, 1994, 1998, 1999 and 2000; the estimated SSB at the beginning of 2015 was $27,000 \mathrm{t}$ (Figure 32 and Table 14). Preliminary estimates for the 2013 year class at Age 1 were extraordinarily high for this stock at 317 million recruits.

## REFERENCE POINTS

The terms of reference for the 2016 framework for 4X5Y Haddock requested the estimation of a removal fishing mortality reference ( $\mathrm{F}_{\text {ref }}$ ) and a biomass limit reference point ( $\mathrm{B}_{\mathrm{lim}}$ ). The output data from the VPA formulation with M fixed at 0.2 , except $0.3,0.6$, and 0.9 for Ages 10-11+ for the three 5-year time blocks (2000-2004, 2005-2009, and 2010-2014; respectively) was used for reference point calculations. Although errors in aging are likely in the earlier time period in the fishery and survey age samples (1970-1984), the productivity during this period appears high based on the research survey biomass index trends (Figure 16). Ignoring this period of higher productivity information could have significant implications on reference point calculations. Therefore, a trial VPA run including the earlier time period (1970-1984) fishery and survey data was conducted. The survey abundance time series was split in 1985 in order to reduce the impact of the ageing error in the earlier period (1970-1984) on the recent period (1985-2014) population abundance estimate. The Ages 4-10 biomass from the "model predicted" and "survey observed" were compared, and the fit was deemed acceptable (Figure 33). The SSB and recruitment data from this run was then used as sensitivity run for the reference points calculations.

## $F_{\text {REF }}$

For the harvest strategy to be compliant with the DFO Precautionary Approach, $\mathrm{F}_{\text {ref }}$ is the maximum acceptable removal rate for the stock and is adjusted depending on the stock's status. For 4X5Y Haddock, the proxy $\mathrm{F}_{0.1}$ or $\mathrm{F}_{40 \%}=0.25$ was the current $\mathrm{F}_{\text {ref }}$ that was derived using output data from an earlier assessment. For the new proposed framework model, and considering the significant changes in fishery selectivity, growth and natural mortality since 2000, the average of the most recent 15 years (2000-2014) of PR, natural mortality, fishery weight at age, spawning stock weight at age and maturity at age were used for the per recruit analysis (Table 15). $\mathrm{F}_{0.1}$ was calculated as 0.44 and $\mathrm{F}_{40 \%}$ as 0.4 , which are much greater than 0.25 . Changes in M on the Ages 10-11+ potentially caused this difference. For the per recruit analysis, M only impacts the trade-off between the gains from leaving fish in the water to grow bigger versus the losses of fish over time due to natural mortality. However, when there is a positive stock-recruitment (SR) relationship, per recruit analyses will tend to overestimate $F_{\text {ref }}$ since it does not consider the relationship between conserving biomass in the water to increased recruitment and yield in the future (sustainable recruitment) (Duplisea 2012). Several studies have demonstrated that using reference point estimates that do not incorporate variation
in recruitment are likely to result in unexpected population declines or even collapse when productivity is low (Brooks 2013, Morgan et al. 2014).
Fishing mortality at Maximum Sustainable Yield ( $F_{\text {msy }}$ ) has been internationally accepted as the limit of $\mathrm{F}_{\text {ref }}$. The Sissenwine-Shepherd age structured production model (Sissenwine and Shepherd 1987), which incorporates a stock-recruitment relationship with the per-recruit results, was applied to 4X5Y Haddock. $\mathrm{F}_{\text {loss }}$, the fishing mortality under which the replacement line gives an equilibrium at the lowest observed spawning stock biomass, has been suggested as a proxy for $\mathrm{F}_{\text {crash }}$ (Cook 1998; O'Brien 1999), and was calculated here for 4X5Y Haddock. It is known that Haddock recruitment events are highly episodic and not well described by traditional stock recruitment relationships. Considering the importance of model uncertainty on reference point calculations, a range of parametric and non-parametric SR models were compared: Ricker, Beverton-Holt (B-H), Hockey Stick (HS), and LOESS smoother (Cleveland 1979).

The estimated proxy values for $F_{\text {ref }}$ are shown in Table 16 and Figures 34-38. The Ricker model estimated $F_{\text {msy }}$ at 0.25 and $F_{\text {loss }}$ at 0.29 using the long time series SR data (1970-2014).
However, with fitting the shorter time series data (1985-2014), the $F_{\text {msy }}$ was estimated as high as 0.6 with estimated SSB $_{\text {msy }}$ below the lowest observed SSB (Table 16 and Figure 34), which was not considered precautionary and 0.6 was not valid as $\mathrm{F}_{\text {ref. }}$. For the B-H model, the profile likelihoods and likelihood surfaces showed that the SR parameters and hence the corresponding production model reference points were not well determined (Figure 35). For the HS model, an iterative grid search method was used for parameter estimation (O'Brien et al. 2003) and calculated $\mathrm{F}_{\text {msy }}=\mathrm{F}_{\text {crash }}=0.3$ (Table 16 and Figure 36). For the LOESS smooth model, there can be large uncertainties with the selection of the LOESS smooth parameter so the joint probability of $\mathrm{F}_{\text {loss }}$ under different smoothing parameter values was calculated. For the current $F_{\text {ref }}=0.25$, there was a $25 \%$ probability that this value would exceed $F_{\text {loss }}$ (Figure 37).
Sissenwine and Shepherd (1987) suggest when SR relationships are poorly determined, an alternative reference point based on SR data, $F_{\text {rep }}$, can be found by finding the fishing mortality rate that produces a replacement line with a slope that equals the average survival ratio. $F_{\text {rep }}$ could be estimated from the median survival ratio ( $F_{\text {median }}$ ). For 4X5Y Haddock, the estimated $F_{\text {median }}=0.15$ (Table 16, Figure 38), which is the level of fishing mortality where recruitment has been more than sufficient to balance losses to fishing mortality in half the observed years (Gibson and Myers 2003). However, the current $\mathrm{F}_{\text {ref }}=0.25$ corresponded to a replacement line where only $35 \%$ of the observed years of R/S were above this line (Figure 38), which means that at this level of fishing, it was expected the stock would be fished below the average level.
$F_{\text {ref }}$ is used in fishery management as a tool to help ensure that removals are at a level that can be sustained by the population.
Despite the uncertainties with the estimate of $\mathrm{F}_{\text {ref }}$ for 4 X 5 Y Haddock (Table 16), the framework meeting participants agreed that $F_{\text {ref }}$ of 0.25 , an estimated $F_{\text {msy }}$ value from the Ricker model with a $25 \%$ probability exceeding $F_{\text {loss }}$ based on LOESS analysis, would be a removal fishing reference when the stock is in the Healthy Zone. However, the current estimated population biomass is at low levels compared to the historic data. $F_{\text {median }}=0.15$ from the replacement line analysis was suggested as a more appropriate target for 4 X 5 Y Haddock in the Cautious Zone.

## $B_{\text {LIM }}$

According to the DFO precautionary approach, $\mathrm{B}_{\text {lim }}$ is the stock level below which productivity is sufficiently impaired to cause serious harm to the resource.

At the 2002 National Workshop on Reference Points for Gadoids (DFO 2002), five computational methods were considered for defining limit reference points in terms of SSB. These five methods were (DFO 2002, p. 10):
$B_{\text {recover: }}$ the lowest historical biomass level from which the stock has recovered readily.
$S b_{50 / 90}$ : the SSB corresponding to the intersection of the 50th percentile of the recruitment observations and the replacement line for which $10 \%$ of the stock-recruitment (S-R) points are above the line.
$\mathrm{BH}_{50}$ : the SSB at which expected average recruitment is one half of the maximum recruitment predicted by assuming an underlying B-H stock-recruit relationship (i.e. the recruitment that is $50 \%$ of the value at the asymptote).
$R K_{50}$ : the lower SSB at which expected average recruitment is one half of the maximum recruitment predicted by assuming an underlying Ricker-type stock-recruit relationship (i.e. the recruitment that is $50 \%$ of the value at the peak of the dome).
$N P_{50}$ : estimate of the lowest SSB where the expected median recruitment is one half of the maximum recruitment calculated by non-parametric analysis (i.e. the recruitment that is $50 \%$ of the largest median recruitment achievable at any SSB within the range of historic observations).

At the workshop it was felt that a comparison amongst the five $B_{\text {lim }}$ candidates provided some insight into the certainty of advice. These methods were applied to the full 4X5Y Haddock stockrecruitment data time series (1970-2014).

For 4 X 5 Y Haddock, $\mathrm{BH}_{50}$ was not well defined (Figure 35). $\mathrm{NP}_{50}$ was not considered for the LOESS smoother model due to the uncertainties of model fit. $\mathrm{RK}_{50}$ was estimated as $9,564 \mathrm{t}$ and $S b_{50 / 90}$ was calculated as $15,866 \mathrm{t}$ for this stock, both using the longer time series of SR data (Figure 39). However, the two values were below the lowest observed biomass of 16,800 t in 2012. For resources that are considered fully exploited, $\mathrm{B}_{\text {lim }}$ proxies that are lower than the lowest observed biomass may not be consistent with the intent of the precautionary approach. $B_{\text {lim }}$ is defined as the biomass level below which serious harm is occurring and secure recovery cannot be achieved. From the biomass history, the 4X5Y Haddock stock has been exposed to full exploitation over an extended time series and has recovered from a low level, 19,700 t in 1994 ( $\mathrm{B}_{\text {recover }}$, Figure 40).

At the Framework meeting, it was agreed that the poor stock recruit relationship precludes the calculation of an appropriate $\mathrm{B}_{\text {lim }}$, so $\mathrm{B}_{\text {recover }}(19,700 \mathrm{t})$ was recommended as a lower reference. In this context, $\mathrm{B}_{\text {recover }}$ is defined as the lowest point on record from which the stock has recovered readily, but it is not necessarily the lowest level from which recovery is possible ( $\mathrm{B}_{\text {lim }}$ ). It is therefore a more conservative reference point than $\mathrm{B}_{\text {lim }}$.

## PROJECTION AND RISK ANALYSIS

The terms of reference for this framework also requested determining the forecasting methodology for providing advice on harvest levels including the risk of falling below biological reference points. The 4 X 5 Y Haddock age-structured fishery and survey information were updated to 2014. Beginning of terminal year (2015) population abundance was estimated from the proposed three 5 -year block (2000-2004, 2005-2009, and 2010-2014) VPA model. The projection and risk analysis shown here is only to illustrate how this outlook can be provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2016 and 2017 had they been pursued in 2015. Uncertainty about current biomass generates uncertainty in forecast results, which was expressed here as the risk of exceeding the proposed
limit $F_{\text {ref }}=0.25$ in 2016 and 2017, and the probability of adult biomass changes relative to 2016 and to 2017.
The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, they are dependent on the data and model assumptions and do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect stock dynamics closely enough, and/or retrospective bias. These projections assume that the current productivity conditions will persist over the projection period. The most recent 5 year average of fishery weight at age, beginning of year population weights at age and fishery PR, as well as the most recent 10 years of geometric mean of recruitment at Age 1 (excluding the exceptional strong 2013 year class), were used as inputs for the projection (Table 17). The catch in 2015 was assumed to be equal to the $5,100 \mathrm{t}$ quota.

Illustrative projections were conducted to evaluate the differences in stock status and catch levels using different harvest strategies. Deterministic projections under a constant quota of $5,100 \mathrm{t}$ are summarized in Table 18. A stochastic projection to provide the risk of F in 2016 exceeding $\mathrm{F}_{\text {ref }}=0.25$ under different catch levels and that risk that the 2017 biomass would not increase by $20 \%$ compared to 2016 are shown in Figure 41. The absolute size of the 2013 year class was the largest source of uncertainty in this exercise. As the projection horizon increases, the contribution of the 2013 year class becomes more important. Therefore, another sensitivity projection was conducted by assuming the 2013 year class recruitment equals the second largest recruitment in the history at 52 million. The deterministic and stochastic results for this sensitivity projection are shown in Table 19 and Figure 42.

## GUIDANCE ON INTER-FRAMEWORK REVIEW

Haddock stocks are known for dramatic changes in recruitment. The fishery PR used in the projection was 0.2 for Age 3 and 0.5 for Age 4 . The assumptions on the strength of upcoming year classes will have significant impacts on stock size and catch advice in the multi-year projections. The following approach for the years between frameworks is proposed:
A two year projection, based on the VPA results, using the most recently available survey and fishery information will be conducted in the full assessment year. The catch advice in the following year will be based on the first year projection.
For the second year, science will provide catch advice based on an interim stock status update, which will be reported as a CSAS Special Science Response. This report will be created by comparing the projections from the full assessment with the updated fishery and survey information, which includes total fishery catch and swept area survey biomass. If age-structured survey and fishery information is available, the document will include a comparison of the strong year classes to the proportion expected from the projection and will monitor possible growth changes. The format is shown in Appendix 1.
For the third year, 2018, the random walk model will be re-run to ensure the M estimates from the framework are still valid. If the M estimates are similar, VPA will be run using an 8 year block (2010-2018) for the most recent years and another 2-year projection will be created. The catch advice for the third year will be based on this projection and reported as CSAS Science Response.
For the fourth year, a similar approach to the second year will be used.
At the framework meeting, it was agreed that the above schedule will be followed unless the following triggers for a full assessment occur:

A difference in strong year class projected versus realised. In this case, if the perception of 2013 year class strength goes below the second highest observed year class, (i.e. below the value used for sensitivity analysis (1999 year class) and outside the range of sensitivity projections), then a more complete review will be conducted.

Low survey biomass trigger (Suggested a 3 year running q adjusted average below $\mathrm{B}_{\mathrm{lim}}$ ) using the previous year's q values.

## RESEARCH RECOMMENDATIONS

The high M used in the recommended framework model could be aliasing fish moving to adjacent areas or deeper waters where the fishery or survey cannot catch them. Noteworthy is that the adjacent Haddock stock on Eastern Georges Bank also shows high Z on older (Age 8+) fish (Stone et al. 2015). Research on a possible mechanism for high M on older ages would help to understand the population dynamics of 4X5Y Haddock. In addition, research on changes in growth/productivity over time and factors influencing the production of exceptionally strong year classes would also be helpful.

## ACKNOWLEDGEMENTS

We thank Doug Swain for providing the ADMB source Code to run VPA models with random walks in $M$ and $P$. Comeau for aging the 4Y5Y Haddock samples.

## TABLES

Table 1. Reported annual and fishing year catch (t) of Haddock from NAFO Division 4X, 1970-2015. Canadian landings include 5Y. FY: Fishing Year; TAC: Total Allowable Catch.

| Year | Catch | TAC | FY Catch ${ }^{1}$ | FY TAC ${ }^{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| 1970 | 18,072 | 18,000 | - | - |
| 1971 | 17,592 | 18,000 | - | - |
| 1972 | 13,483 | 9,000 | - | - |
| 1973 | 13,106 | 9,000 | - | - |
| 1974 | 13,378 | 0 | - | - |
| 1975 | 18,298 | 15,000 | - | - |
| 1976 | 17,498 | 15,000 | - | - |
| 1977 | 21,281 | 15,000 | - | - |
| 1978 | 27,323 | 21,500 | - | - |
| 1979 | 25,193 | 26,000 | - | - |
| 1980 | 29,210 | 28,000 | - | - |
| 1981 | 31,475 | 27,850 | - | - |
| 1982 | 25,729 | 32,000 | - | - |
| 1983 | 27,405 | 32,000 | - | - |
| 1984 | 21,156 | 32,000 | - | - |
| 1985 | 16,131 | 15,000 | - | - |
| 1986 | 15,555 | 15,000 | - | - |
| 1987 | 13,780 | 15,000 | - | - |
| 1988 | 11,272 | 12,400 | - | - |
| 1989 | 6,800 | 4,600 | - | - |
| 1990 | 7,556 | 4,600 | - | - |
| 1991 | 9,826 | 0 | - | - |
| 1992 | 10,530 | 0 | - | - |
| 1993 | 6,968 | 6,000 | - | - |

Table 7. DFO Summer survey total biomass index (t) for 4X5Y Haddock calculated separately for Bay of Fundy Strata (482-495), western Scotian Shelf Strata (470-481) and both areas combined, 1970-2015. (Average is for 1970-2015). A conversion factor of 1.2 has been applied to indices from 1970-1981 to account for vessel and gear changes.

| Year | Total Biomass Index (t) |  |  |

Table 8. DFO Summer survey total abundance index at age (000's) for $4 X 5 Y$ Haddock calculated separately for Scotian Shelf Strata (470-481) and Bay of Fundy Strata (482-495) then combined, 1970-2014. A conversion factor of 1.2 has been applied to indices from 1970-1981 to account for vessel and gear changes. Abundance at age data from 1985-2014 is used for framework modelling.

Table 9. Weighted DFO Summer survey mean weight at age (kg) of 4X5Y Haddock for Ages 0-14 calculated separately for Scotian Shelf Strata (470-481) and Bay of Fundy Strata (482-495) then combined after weighting by total number, 1970-2014. Cells with dashes have no data available. WAA data from 1985-2014 is used for framework modelling.

## FIGURES

Figure1. Map of the 4X5Y Haddock management area and Canadian Statistical unit areas for the Bay of Fundy (4Xqrs) and western Scotian Shelf (4Xmnop). Separate age length keys for the western Scotian Shelf and Bay of Fundy are used for calculating the catch at age and survey age-specific indices of abundance. Haddock landed from statistical areas 5Zem and 5Zej are not included in the 4X5Y Haddock stock assessment.

Figure 2. Retrospective results from sequential population analysis (SPA) for 4X5Y Haddock from the 2012 assessment (Showell et al. 2013) for Ages 6-9 fishing mortality (top panel), and 4+ biomass (bottom panel) as successive years of data were removed from the assessment.

Figure 3. Reported annual landings (t), fishing year landings (FY; April $1^{\text {st }}-$ March $31^{\text {st }}$ ) and TAC for the 4X5Y Haddock fishery, 1970-2015.

Figure 4. Percentage of annual landings (t) by gear type for the 4X5Y Haddock fishery, 1970-2015. TC 13 = otter trawl tonnage class 1-3; TC 4+ = otter trawl tonnage class 4+; LL = longline.

Figure 5. Annual landings (t) by Canadian statistical unit area for the 4X5Y Haddock fishery, 1985-2015.

Figure 6. Annual landings (\%) by gear sector for Canadian statistical unit areas representing the western Scotian Shelf (SS; 4Xmnop) and Bay of Fundy (BoF; 4Xqrs5Y) areas of the 4X5Y Haddock fishery, used in catch at age calculations for 1985-2014.

Figure 7. Distribution of 4X5Y Haddock catches (t) by gear type for 2005, 2010 and 2015.

Figure 8. Haddock landings ( $000 \mathrm{~s} t$ ) from $4 X$ p south (i.e. within 5 nautical miles north of $4 X 5 Z$ line), and all other statistical unit areas within the 4X5Y management unit for 2004-2014. Numerical values represent the percentage of total catch taken from the $4 X p$ south area.

Figure 9. 4X5Y Haddock landings (t) from Small Mesh Otter trawl (Cod end mesh size: 110-112 mm diamond) and \% of total annual landings,1991-2014.

Figure 10. Catch at age for $4 \times 5$ Y Haddock for Ages 1-14, 1985-2014. The area of the circle is proportional to the catch at that age and year. Two examples of recent strong cohorts are highlighted: 2003 (red) and 2010 (black). Data from 1985-2014 is used for framework modelling.

Figure 11. Commercial fishery mean length at age (cm) by area [Scotian Shelf (SS) and Bay of Fundy (BoF)] and gear type(mobile and fixed) for 4X5Y Haddock Ages 3, 5, 7, and 9 for 1985-2014.

Figure 12. Commercial fishery mean weight at age (kg) by area [Scotian Shelf (SS) and Bay of Fundy (BoF)] and gear type (mobile and fixed), as well as the combined weight at age for 4X5Y Haddock Ages 3, 5, 7, and 9 for years 1985-2014.

Figure 13. 4X5Y Haddock commercial fishery catch at size by area (SS: Scotian Shelf; BoF: Bay of Fundy) and gear type (M: mobile; F: fixed) summed over year intervals, 1985-2015.

Figure 14. Distribution of $4 X 5 Y$ Haddock catches ( 5 and 10 year average weight $(\mathrm{kg}) / t o w$ aggregated by 10 minute squares) from DFO Summer survey Strata 470-495, 1970-2015. Grey shading indicates extent of area surveyed.

Figure 15. DFO Summer survey strata and area of coverage for Scotian Shelf (Strata 470-481, blue shading) and Bay of Fundy (Strata 482-495; pink shading) areas of 4X5Y.

Figure 16. Trends in the total biomass index (000 t), including all ages, from the DFO Summer survey for Scotian Shelf (Strata 470-481), Bay of Fundy (Strata 482-495) (left panel) and both areas combined (4X5Y; right panel) compared to the long term average for each series from 1970-2015. A conversion factor of 1.2 has been applied to total biomass estimated for 1970-1981 to account for vessel and gear changes.

Figure 17. Stratified total number per tow at age (1-13) for $4 X 5 Y$ Haddock from the DFO Summer survey, Strata 470-495, 1985-2014. Recent strong year classes are indicated by the yellow (2003) and red (2010) circles. The black circle represents the 2013 year class at Age 1 in 2014. The area of the circle is proportional to the catch at that age and year. Abundance at age data from 1985-2014 is used for framework modelling.

Figure 18. DFO Summer survey mean length at age (cm) for each strata (Scotian Shelf and Bay of Fundy); as well as the mean weighted length at age for 4 X5Y Haddock Ages 3, 5, 7, 9, and 11 1985-2014. Mean weighted lengths at age were calculated separately for Bay of Fundy and western Scotian Shelf Strata then combined after weighting using total abundance at age from each strata.

Figure 19. DFO Summer survey mean weight at age (kg) for each strata (Scotian Shelf and Bay of Fundy); as well as the mean weighted weight at age (Combined) for 4X5Y Haddock Ages 3, 5, 7, 9, and 11 for 1985-2014. Mean weighted weights at age were calculated separately for Bay of Fundy and western Scotian Shelf Strata then combined after weighting using total abundance at age from each strata.

Figure 20. Comparison of DFO Summer survey and commercial fishery mean weight at age (kg) for Ages 3 and 5 (upper panel) and Ages 7 and 9 (lower panel) for Haddock from the 4X5Y management area, 1985-2014.

Figure 21. Relative fishery selectivity at age for $4 X 5 Y$ Haddock from two time periods before and after 1994 calculated using the method of Clark (2014).

Figure 22. The 1985-2014 relative $F$ (left) calculated as the ratio of fishery catch at age over the survey catch at age; and survey $Z$ (right) calculated from the DFO Summer survey catch at age for 4X5Y Haddock.

Figure 23. Estimated survey $Z$ (top) and relative F (bottom) on Ages 5-9 and Ages 10+ by tracking each cohort for 4X5Y Haddock. The blue vertical reference lines represent strong cohorts.

Figure 24. Natural mortality estimated from the 3 VPA models with time-varying natural mortality (M) on different age groups for 4X5Y Haddock. A) from the model with 2 M age groups: 1-3 and 4+; B) from the model with $3 M$ age groups: 1-3, 4-6, and $7+; C$ ) from the model with $4 M$ age groups: 1-3, 4-6, 7-9, and 10+.

Figure 25. Residuals from the VPA model with time-varying natural mortality on 4 age groups: 1-3, 4-6, 79, and 10+ for 4X5Y Haddock.

Figure 26. The retrospective analysis from the VPA model with time-varying natural mortality on 4 age groups: 1-3, 4-6, 7-9 and 10+ for 4X5Y Haddock. The top panel shows the spawning stock biomass (SSB) and bottom panel shows the fishing mortality (F6-9).

Figure 27. Residuals from the VPA model with a constant natural mortality of 0.2 for $4 X 5 Y$ Haddock.

Figure 28. Residuals from the ADAPT VPA model formulation of $M$ fixed 0.2 , except at $0.3,0.6$, and 0.9 for Ages 10-11+ for the three 5-year times block (2000-2004, 2005-2009, and 2010-2014, respectively) for 4X5Y Haddock.

Figure 29. Survey catchability $(q)$ at age estimated from ADAPT VPA model formulation of $M$ fixed at 0.2, except 0.3, 0.6, and 0.9 for Ages 10-11+ for the three 5-year time blocks (2000-2004, 2005-2009, and 2010-2014; respectively) for 4X5Y Haddock.

Figure 30. Retrospective analysis for the ADAPT VPA model formulation of M fixed at 0.2, except 0.3, 0.6 , and 0.9 for Ages 10-11+ for the three 5-year time blocks (2000-2004, 2005-2009, and 2010-2014; respectively) for 4 X 5 Y Haddock.

Figure 31. The population number weighted average fishing mortality over Ages 6-10 ( $F_{6-10}$ ) from the ADAPT VPA model formulation with M fixed at 0.2, except 0.3, 0.6, and 0.9 for Ages 10-11+ for the three 5-year time blocks (2000-2004, 2005-2009, and 2010-2014, respectively) for 4X5Y Haddock.

Figure 32. Biomass (000s t) of Ages 4-10 for 4X5Y Haddock from ADAPT VPA model formulation with M fixed at 0.2, except 0.3, 0.6, and 0.9 for Ages 10-11+ for the three 5-year time blocks (2000-2004, 20052009, and 2010-2014; respectively) compared with q adjusted DFO Summer survey biomass.

Figure 33. The model predicted and observed q adjusted DFO Summer survey biomass, Ages 4-10, for 4 X5Y Haddock. The solid lines indicate more recent years (1985-2014), when aging data is believed to be more accurate and broken lines indicate the early portion of the series that was not re-aged.

Figure 34. The fitted stock recruitment (SR) relationship with the Ricker SR model for 4X5Y Haddock using the output data from the ADAPT VPA formulation of $M$ fixed at 0.2 , except $0.3,0.6$, and 0.9 for Ages 10-11+ for the three 5-year time blocks (2000-2004, 2005-2009, and 2010-2014; respectively). The upper panel shows the result using a longer time series (1970-2014) and the lower panel with a shorter time series (1985-2014) of SR data. $F_{l o s s}, F_{\text {msy }}$ and the replacement line when there was no fishing $\left(S P R_{F=0}\right)$ are shown when applicable.

Figure 35. The fitted stock recruitment (SR) relationship with the B-H SR model for 4X5Y Haddock using the output from the ADAPT VPA formulation of $M$ fixed at 0.2 , except $0.3,0.6$, and 0.9 for Ages 10-11+ for the three 5 -year time blocks (2000-2004, 2005-2009, and 2010-2014; respectively). The upper panel shows the point estimate using maximum likelihood method. The lower panel shows the likelihood profile of B-H model parameters.

Figure 36. The fitted stock recruitment (SR) relationship with HS model I for $4 X 5 Y$ Haddock using the output from the ADAPT VPA formulation of M fixed at 0.2 except, $0.3,0.6$, and 0.9 for Ages 10-11+ for the three 5-year time blocks (2000-2004, 2005-2009, and 2010-2014; respectively). The upper panel shows the result using a longer time series (1970-2014) and the lower panel with a shorter time series(19852014) of SR data. The dashed red line represents the replacement line, when there is no fishing (SPR $\mathrm{F}_{F=0}$ ).
probability of spr at Floss

Figure 37. The probability of Spawner per Recruitment at $F_{\text {loss }}$ when the SR relationship was fitted using the LOESS smooth method for 4X5Y Haddock.

Figure 38. The fishing mortality corresponding to different percentile of replacement line for 4X5Y Haddock.

Figure 39. The $S b_{50 / 90}$ for $4 X 5 Y$ Haddock. The dashed line represents the $50^{\text {th }}$ percentile of the recruitment observations and the solid line represents the replacement line for which $10 \%$ of the stockrecruitment points are above.

Figure 40. $B_{\text {recover }}$ for $4 X 5$ Y Haddock.

Figure 41. Stochastic projection to provide the risk of exceeding $F_{r e f}=0.25$ and the probability of 2017 biomass will not increase by 20\% under different catch in 2016 for 4X5Y Haddock.

Figure 42. Sensitivity run for stochastic projection to provide the risk of exceeding $F_{\text {ref }}=0.25$ and the probability of 2017 biomass will not increase by $20 \%$ under different catch in 2016 for $4 X 5$ Y Haddock. The 2013 year class was adjusted to second largest recruitment in the time series.

## APPENDIX: CSAS SCIENCE RESPONSE FORMAT FOR 4X5Y HADDOCK

## SUMMARY

A brief list of summary bullets.

## Context

Based on two-year projection approach.
Provide the history on the assessment/update schedule.

## FISHERY

An update on fishery landings, include a brief paragraph description and data in table format (e.g. a shortened version of Table 1).

Document any changes in fishing practices, if applicable.

## Indicators and Recommendations

- Provide updated DFO Summer RV survey total biomass index.
o Describe the 2016 biomass estimate from survey relative to long term trends and include a biomass index figure (Figure 15).
o Compare q-adjusted survey biomass with the long term mean and projected biomass from the most recent full assessment.
o Note any changes to survey (e.g. timing) that should be considered in next full stock assessment.
- If survey and fishery ageing is available for the survey and fishery:
o Update age-specific indices and fishery catch, describe the features of the age distribution, noting if there are any unexpected apparent differences in the year class strength compared to the projection from the most recent full assessment.
o Update DFO survey WAA (beginning of year population), and compare with what was used in the projection from most recent full assessment.
- Comment on performance of recent quotas relative to expected risk and the most recent retrospective pattern:
o Describe recent quotas and their associated risk (for F exceeding $F_{\text {ref }}$ and for B not increasing), recent catch (as a fraction of those quotas), and whether the estimated $F$ and B were consistent with the risk level for the specified quota.
o Describe the direction and magnitude of retrospective pattern from recent assessments.

## CONCLUSIONS

Using interim results described in the previous section (comparison of survey results to historical time series, comparison of survey results to VPA projections, weights at age, quota performance and retrospective pattern), determine whether the catch advice from the projection is still valid and include a table of indicators that provide support for either 1) maintaining existing catches advice, or 2 ) reducing catch advice.

[^0]:    ${ }^{1}$ Fishing year in 1999 was extended to March 3, 2000. TAC prorated upwards. Subsequent fishing years begin on April $1^{\text {st }}$.

[^1]:    ${ }^{1}$ Mobile gears include all kinds of trawls (e.g. otter, midwater, shrimp) and pair sSeine.
    ${ }^{2}$ Miscellaneous gears include trap, unknown gears, dredge, jigger, pot, squid jig and weir.
