EXECUTIVE SUMMARY

The purpose of the air tightness testing was to measure the degree to which unintentional openings had been avoided in the construction of the Apple Hill homes; and to evaluate the usefulness of various air tightness testing techniques.

A total of 35 houses were tested at three month intervals, over a period of one year. The tests were conducted in three configurations:

1. A depressurized test in accordance with the draft procedures of the CGSB Standard 14A GP 10M.
2. A pressurized air tightness test following the same procedures as the CGSB Standard.
3. A depressurized test with all intentional openings sealed. These include the furnace room, bathroom vents, dryer vents, and fireplace.

Based on these test, the normalized equivalent leadage area (NELA), and air change rates at 50Pa (AC $\S$ 50Pa) for gas heated houses are:

	<u>NELA(cm<sup>2</sup>/m<sup>2</sup>)</u>	<u>AC<math>\S</math>50Pa</u>
CGSB	3.2	3.86
Pressurized	3.4	4.07
Depressurized Seal	1.8	2.43

The Apple Hill homes are tighter, relative to other new housing in the same area, but not as tight as would be expected for new energy efficient standards. Current standards for R-2000 houses call for AC $\leq$ 50Pa to be less than 1.50. These are standards which only the electrically heated houses come close to meeting. The furnace room in gas heated houses appears to be the major contributor to the air leakiness of these houses. The gas heated houses are 30 to 70% leakier than the comparable electrically heated houses.

Both CGSB, and depressurized sealed tests provide reliable and reproducible results. The pressurized test is impractical, due to inconveniences to the homeowner during winter tests. The depressurized sealed test provides a useful measure for assessing the vapour barrier integrity only, while the current CGSB Standard provides a measure of the overall tightness of the above grade envelope. Some clarification of the draft CGSB Standard is required, in terms of

- defining the envelope area, and heated volume more rigorously;
- clarifying the necessary preparation of heat exchangers for testing;
- analysing the temperature correction term for flow.

## 1.0 INTRODUCTION

The field of airtightness testing has received considerable attention, since the mid-seventies, as a useful and relatively quick method of rating the integrity of the air/vapour barrier of a house. The fan depressurization method has been performed on several hundred houses in Canada by both independent contractors, and many Government related building research departments. The results fo the airtightness tests are not only uses to rate houses, but are becoming increasingly important in terms of providing key parameters for many natural infiltration models. With the growing demand for tighter homes, in reponse to increased energy costs, recommendations are presently being discussed to incorporate airtightness testing results as a measure of the thermal performance of new and existing houses.

Airtightness test results could become a reliable source of information for comparison analysis, as these results are less sensitive to local weather conditions (in contrast to tracer gas techniques), but this would require well defined test guidelines and standards. Numerous pressurized, depressurized CGSB, and depressurized sealed tests were performed in the Apple Hill subdivision. Evaluations of each test procedure, in terms of reliability, reproductibility, and practicability are documented, with regard to potential delineation of guidelines and standards.

## 2.0 OBJECTIVES

The purpose of this series of tests was:

- To measure the degree to which unintentional openings in the building structure had been avoided.
- To identify the distribution and magnitude of specific air leakage sites.
- To evaluate the usefulness of the draft CGSB Standard for airtightness in building in terms of reliability, cost, time, significance of data, equipment specifications: and compare this with other procedures.

This report presents the results of airtightness tests conducted in various configurations, during the four testing phases of the Study of Apple Hill Energy Efficient Homes. The test procedures are discussed and evaluated. The results of airtightness tests are compared between houses, models, and test phases, in order to make conclusions concerning the airtightness of Apple Hill Homes.

### 3.0 METHODOLOGY

Three types of airtightness tests were carried out to meet these objectives:

1. An airtightness test conducted according to detailed procedures of the draft CGSB Standard 14A GP 10M (third draft, January 1982). A copy of this draft is presented in Appendix 2-A. It should be noted that significant changes in this procedure have been incorporated in later drafts.
2. A pressurized airtightness test following the same procedure as 1.
3. A depressurized test with all the intentional openings sealed. These included those of the furnace room, bath vents, dryer, and fireplace. These are not normally sealed in the CGSBS Standard test.

The first airtightness test was the pressurization test on a house prepared to the CGSB Standard. Then the door fan unit was reversed and the house was depressurized in this condition. Finally, the house had all intentional openings sealed and a second depressurization test was completed. Phase 4 tests omitted the pressurized test, as most homeowners would not permit cold winter air to be blown into their house.

There was initially some question as to how the CGSB Standard should be applied to houses with enclosed furnace rooms. The Standard required that the flue of the furnace and hot water tank be sealed if they are located within a heated space of the house. Since the enclosed furnace room was essentially isolated from the heated space, both thermally and aerodynamically, it was decided that the CGSB Standard would not permit the sealing of these flues for test purposes. Consequently, the CGSB test in Apple Hill homes entailed only the closing of exterior doors and windows, and the closing of dampers on vents. There was no sealing whatsoever in the house. This practice is confirmed in CGSB Standard Draft #5. Leak location checklists were completed during the first phase of airtightness testing.

#### 4.0 EVALUATION OF TEST PROCEDURE

Analysis of the airtightness test summaries, in Appendix 2-B, shows that the airtightness test is the most reproducible of all tests performed in the Apple Hill project.

Some qualification of the test results follows:

1. Calculation of house volumes and envelope areas should be rigorous and double checked, particularly for research purposes. Errors are easy to make, and seem deceptively insignificant. Any comparison of model-to-model airtightness tests, results (NELA or AC $\S$ 50Pa) of one airtightness survey to another, are directly dependent on accurate envelope areas or house volumes. This report uses total house heated volume within the vapour barrier (including basement), and total above grade envelope area including doors and windows.
2. Phases 2,3, and 4 have comparable data using identical equipment, and technicians. Phase 1 data reflects the variability of equipment used to establish a good testing procedure. It also does not include sealing the hot water flue in many sealed tests, and oversight that occurred in phase 1 testing.
3. Based on the data from phases 2,3, and 4, it is difficult to see any significant seasonal trend in airtightness. All seasons showed roughly the same values for NELA and AC $\S$ 50Pa, with perhaps a moderate increase in leakiness in cold weather testing.

4. Pressurized test results during the summer months were generally higher than depressurized test results. In other words, the houses were leakier for the pressurized test than for the depressurized test. The opposite was found in cold weather testing (see Table 4.1: A comparison of Pressurized vs. Depressurized CGSB Tests by Model Means).

It is hard to imagine how this reversal is caused by seasonal changes in structural characteristics of the house. However, it is quite apparent that the temperature correction factors used to modify airflow in the CGSB equations would cause this trend. This suggests that some testing on a control house under various temperature conditions might be informative.

TABLE 4.1

COMPARISON OF PRESSURIZED VS DEPRESSURIZED CGSB TESTS BY MODEL MEANS

Mean Model A.C. § 50 Pa (no electric houses)

Phase	Houses 1-8		Houses 10-18		Houses 20-25		Houses 27-30	
	Pres.	Dep.	Pres.	Dep.	Pres.	Dep.	Pres.	Dep.
1	3.68	3.97	4.52	4.90	4.40	4.67	4.35	4.48
2	3.61	3.32	4.18	3.83	4.20	4.12	4.22	3.91
3	3.59	3.52	4.14	3.79	4.42	4.14	4.22	3.95
4	----	3.60	----	3.91	----	4.32	----	3.83

## 5.0 DISCUSSION OF RESULTS

Airtightness tests have been conducted on all available homes in each of the test phases. Summaries of the airtightness results for the three different types of tests are shown in Tables 5.1, 5.2 and 5.3 with detailed data sheets in Appendix 2-B. Based on this data, equivalent leakage areas (NELA), and air changes at 50 Pa for a representative sample of airtightness testing on gas heated houses, are shown here:

### AIRTIGHTNESS SUMMARY FOR GAS HEATED HOUSES ONLY

	NELA (cm <sup>2</sup> /m <sup>2</sup> )		AC/H @ 50 PA	
	<u>Phase 1</u>	<u>Phase 2-4</u>	<u>Phase 1</u>	<u>Phase 2-4</u>
Depressurized Unsealed (CGSB)	3.8	3.2	4.59	3.86
Pressurized Unsealed	3.8	3.4*	4.26	4.07*
Depressurized Sealed	2.5	1.8	3.50	2.43

\*Note: includes only phases 2 and 3

These results compare favorably with the study of R.K. Beach, "Relative Tightness of New Housing in the Ottawa Area", DBR Building Research Note No. 149-1978. In this study, the average normalized ELA was 3.25 cm<sup>2</sup>/m<sup>2</sup> for the depressurized sealed test, with a range of 1.8 to 5.3 cm<sup>2</sup>/m<sup>2</sup>. The Apple Hill homes are not as tight as would be expected of energy efficient homes. Standards for R-2000 houses require airtightness levels better than 1.5 acph at 50 pascals.

A comparison of sealed and unsealed ELA'S shows a clear reduction in houses that have been sealed. This suggests that dampers or weather-stripping are not functioning as intended. The worst problem is in the furnace room. Results from intensive furnace room studies on four houses revealed that up to 95% of the difference between CGSB and sealed test is attributable to the furnace flues and combustion air inlets. Table 5.4, a comparison of Depressurized Sealed vs. Depressurized CGSB Test, shows that gas houses were 29 to 46 percent tighter when sealed. Electric houses only averaged a 13 percent increase in tightness by sealing, as there were no flues or combustion air inlets to block.

Summary of results, comparing the normalized equivalent leakage are (NELA) and air changes at 50 Pa (AC $\S$ 50) as determined by the CGSB Standard test for each model, is presented in Tables 5.5 and 5.6. Based on these results, the following observation are made:

1. Russett houses, heated electrically, are 30 to 40% tighter in terms of NELA and AC $\S$ 50 than gas heated houses.
2. The electrically heated Cortland model is 60 to 67% tighter than the gas heated models in terms of NELA and AC $\S$ 50.
3. The York electrically heated house is 33 to 53% tighter than the gas heated houses.

4. Houses 50 and 51 have about 20% more envelope area than the Fireside model which is the largest for the Apple Hill homes. When compared to the Fireside, houses 50 and 51 have NELA'S and AC§50's about 50% lower. House 52, which is electrically heated, has a 40% higher NELA and 15% higher AC§50 than the comparable electrically heated Cortland model.
5. When air movement is traced by smoke pencils during air tightness tests, there appears to be a great deal of air infiltrating through the fireplace. When the results of the CGSB test is compared between houses with and without fireplaces, there is no discernible pattern of difference in airtightness.
6. The study of Furnace Room Design involved extensive retrofits to three furnace rooms in the Apple Hill subdivision. The retrofits included airtightening of the furnace room in one case; the installation of a condensing gas furnace in the second case; and retrofitting a power venter to the combustion appliances in the third. These retrofits involved reducing the size of the combustion air inlets, or completely sealing them. This action resulted in improvements of between 20 to 30% in airtightness of the houses.

Leak location checklists were completed for 22 houses. This required depressurizing the house, and identifying leaks with a smoke pencil. Detailed leak location checklists for each house are presented in Appendix 2-D. This checklist revealed several areas with a high frequency of observed leaks:

- 1/ Drywall discontinuities such as outlets, ceiling fixtures, and baseboard;
- 2/ Air/Vapour barrier detail at the ceiling/partition walls;
- 3/ Window and exterior door;
- 4/ Fireplace/wall construction;
- 5/ Basement wall/joist, basement wall/sill, and furnace room door;
- 6/ Attic hatch;
- 7/ Bathroom ceiling vent.

Although the Apple Hill homes are identified as energy efficient homes, it is clear that not enough attention was given to air/vapour barrier detail in the critical areas such as partitions, windows, doors, fixtures etc. The leakage sites are characteristic of omissions in air/vapour barriers.

## 6.0 CONCLUSIONS

1. Airtightness test produced fairly consistent results from phase to phase, season to season.
2. The Apple Hill homes are tighter relative to other new housing in the same areas, but not as tight as would be expected for new energy efficient standards. Current standards for R-2000 houses call for AC $\leq$ 50Pa to be less than 1.5. These are standards which only the electrically heated houses came close to meeting.
3. The furnace rooms in gas heated houses are the major contributors to the air leakiness of these houses. The gas heated houses are 39 to 70% leakier than the comparable electrically heated houses.

## 7.0 RECOMMENDATIONS

Based on the results of the Apple Hill tests, it appears that a pressurized test is impractical as a standard test. This is primarily due to inconveniences to the homeowner during winter tests. Both CGSB and depressurized sealed tests satisfy the criteria of being reliable, and practical. The sealed test, as opposed to the CGSB test, is preferred for assessing air/vapour barrier integrity only, a measure of the degree to which "unintentional" openings have been avoided. Although instructive, it is still recommended that the current CGSB guidelines be used for the standard airtightness test. This test is more analagous to tracer gas test conditons, and better represents the degree of tightness of the whole house envelope, that part of the house exposed to infiltration of exfiltration.

As airtightness testing becomes more prevalent, it is recommended that current draft standard for airtightness be resolved. Based on the testing in Apple Hill, many points in the draft were, and still are unclear. Some of these areas are listed below.

- A rigorous definition of Envelope Area and Heated Volume.
- More clarification on air exchangers and their preparation for testing.
- More analysis of the temperature correction term for flow.

APPENDIX 2-A

DETAILED TEST PROCEDURES

PROCEDURE OF AIR TIGHTNESS TESTING

The steps followed in conducting an air tightness test are similar to those outlined in the CGSB Stanard 14A GP 10M. Apple Hill was unusual in the sense that three tests were being conducted on the same house. It was found to be most efficient to begin with a pressurization test on the house, with intentional openings in a unsealed state; then to reverse the door fan unit and depressurize the house (still it is unsealed conditions); and finally to seal up the house and complete a second depressurization test. By leaving the sealing of the house for the final finding that wind speeds, or mechanical difficulties prevented the collection of valid data, thus rendering the sealing of the house useless.

Third Draft

149-GP-10M

January 1982

CANADIAN GENERAL STANDARDS BOARD  
Standard for  
DETERMINATION OF AIRTIGHTNESS OF BUILDINGS BY  
THE FAN DEPRESSURIZATION METHOD

1. SCOPE AND FIELD OF APPLICATION

1.1 This is a method for the determination of the airtightness of a building's exterior envelope. It is not a method for determining the actual air leakage which occurs through the building envelope under the influence of wind and buoyancy pressures or the operation of ventilation systems.

1.2 The method is applicable to small detached buildings (especially houses) but with appropriate modifications, it can also be used for other buildings or parts of buildings.

2. PRINCIPLE

A fan or fans are used to exhaust air from the building at rates required to maintain specified pressure differences across the building envelope. The air flows and the pressure differences are measured. The intention is to subject the complete envelope under test to a simultaneous and similarly directed air pressure.

3. TERMINOLOGY

Airtightness - the degree to which unintentional openings in the building envelope have been avoided.

Building envelope - that portion of the heated structure which separates conditioned from unconditioned space.

Envelope under test - that portion of the heated structure which separates the space under test from that not under test.

Intentional opening - an opening in the building envelope deliberately made to fulfill a particular function.

4. APPARATUS

4.1 Fan

4.1.1 The fan or fans shall have a total air flow capacity capable of producing a pressure difference of at least 50 Pa between the inside and outside. (Sufficient capacity for testing

new detached houses is normally about 1500 L/s and for older detached houses it is normally 2500 L/s.)

4.1.2 The fan shall have a variable speed control or a control damper in series with the fan.

4.1.3 The fan shall be calibrated in air flow units or be connected to an air flow metering system. The accuracy of air flow measurement shall be + 5%.

4.2 Pressure-measuring apparatus - This device (e.g. a micro-manometer) shall be used to measure pressure differences between 0 and 50 Pa and it shall have an accuracy of  $\pm 2$  Pa.

4.3 Thermometer(s) - This device shall be used to measure temperature in C and it shall have an accuracy of  $\pm 1$ C.

4.4 Sealing apparatus - This apparatus shall be used to seal the fan into a window or a door.

4.5 Pressure averaging box - This device shall be suitable for connection of multiple tubes from exterior pressure taps and shall have a volume of not less than 1 L and a time constant of  $5 \pm 1$  s. Construction and calibration of the pressure averaging box shall be completed as described in Appendix F.

## 5. CALIBRATION OF APPARATUS

5.1 Routine Inspection - After setting up the apparatus, take the following steps to check all the measuring devices.

5.1.1 Visually inspect for various physical defects.

5.1.2 Visually inspect for proper installation in accordance with manufacturer's specification.

5.1.3 Inspect the levelling of devices which require this precaution (e.g. a manometer).

5.1.4 Ensure that all indicators are at zero settings.

5.2 Laboratory Calibration - Calibrate all measuring devices at least once a year and when any major component is replaced.

5.2.1 Calibrate the air flow and pressure measuring devices in accordance with the manufacturer's instructions.

5.2.3 Calibrate the pressure measuring device in accordance with the manufacturer's instructions or alternatively, calibrate it in accordance with Appendix A-3.

## 6. TESTING

### 6.1 Set-Up Procedures

6.1.1 Measure and record the outdoor ambient temperature.

6.1.2 Record the outdoor ambient pressure. (A report from the local weather station should normally be sufficient.)

6.1.3 Include in the test all rooms which are intended to be heated to more than 10C except rooms with separate ventilation (e.g. boiler room and garages.)

6.1.4 Switch off all fuel combustion equipment, exhaust fans, vented dryers and air conditioners.

6.1.5 Shut off all pilot lights on vented gas-fired appliances.

6.1.6 Prepare intentional openings as detailed in Table 1.

6.1.7 Remove ashes from fireplaces. Check chimneys and furnace

flues for excessive soot and do not perform the test if soot is likely to enter the building.

6.1.8 Open all interior doors except those to rooms which are not included in the test (par.6.1.3.)

6.1.9 Install the test apparatus such that air will be exhausted from the building. To eliminate the possibility of disturbance of the flow entering the nozzle when using a bell-mouthed nozzle apparatus, ensure that no obstructions are placed within one throat diameter away from the centre of the nozzle entrance.

If the wind speed reported by the local weather office is greater than 20 km/h, the test should not be conducted. When using a blower door apparatus, ensure that no obstructions are placed within the width of the door and closer than one fan diameter in front of the fan.

6.1.10 Seal the joints between the apparatus and the envelope.

6.1.11 Attach the exterior pressure taps to the exterior walls of the envelope under test such that the square-cut ends point downward. For single unit residences, secure the exterior pressure taps at points at least 2 m above grade if possible, and at the horizontal mid-point of the principal exterior wall facing in that direction. See Figure 2 for the recommended locations of the exterior pressure taps on some common shapes of houses.

6.1.12 Protect the interior and exterior pressure taps from the influence of the fan.

6.1.13 When the building to be tested has walls, ceilings or floors common with the rooms that are not included in the test but which are intended to be heated to more than 10C, make provision to reduce the pressure in the adjacent rooms to match the pressure in the rooms under test at each test point.

6.1.14 For fireplace chimneys without a damper, perform the test without any sealing unless the leakage is so large that the test cannot be performed. In this case, seal the fireplace at the opening and report this matter as a deviation from the usual test procedure in the test report. (See par.7.1, item 0.)

## 6.2 Test Procedures

6.2.1 Switch on the fan or fans.

6.2.2 Adjust the air flow to produce a suitable test pressure difference across the envelope. (See par. 6.2.5.)

6.2.3 Adjust the pressure in any adjacent rooms (par.6.1.13) to achieve a zero pressure difference across common partitions.

6.2.4 When conditions have stabilized, measure and record the air flow in L/s, the pressure difference in Pa and the intake temperature at the fan in C.

6.2.5 Repeat par. 6.2.2 to 6.2.4 at other pressure differences to provide at least four readings at reasonably uniformly spaced pressure differences within the range 10 to 50 Pa.

## 6.2.6 Verification of Data

Determine the correlation coefficient of the fit of the data in

accordance with par. 6.3.3 and Appendix C. Repeat the entire test if the correlation coefficient ( $r$ ) is less than 0.9.8.

6.2.7 When the purpose of the test is to show a reduction in air infiltration rate as a result of sealing unintentional openings, perform the test as described both before and after the sealing work.

#### 6.2.8 Completion of the Test - After the test:

- a) remove all seals applied in accordance with Table 1
- b) reopen dampers as necessary
- c) relight the gas pilot light.

### 6.3 CALCULATIONS

#### 6.3.1 Determination of the Area Envelope Under Test

6.3.1.1 Use interior dimensions when determining the area of the envelope under test.

6.3.1.2 Include all ceilings (flat or sloping), floors and walls (including doors and windows) that are correspondingly below, above and adjacent to unheated spaces and spaces intended to be heated to less than 10c. For example, include

- a) ceilings below unheated attics and roofs
- b) floors above unheated basements (or unheated portions thereof), cellars, crawl spaces, cold storage rooms, garages, and floors exposed to the ambient environment such as floors above carports, floors of bay windows and floors of buildings (or parts thereof) supported above grade
- c) exterior above grade walls and walls adjacent to unheated portions of basements, cellars, crawl spaces, cold storage rooms, unheated porches, garages and stairwells to basement entrances.

6.3.1.3 To conveniently determine the area of the walls, draw the exterior wall to scale on squared paper showing the grade line, the areas not under test and the position of interior walls and ceilings. Count the squares to determine the area of the wall.

6.3.1.4 The area of the envelope under test is the total area of all eligible ceilings, floors and walls.

TABLE 1

Determination of the Volume Enclosed  
by the Envelope Under Test

Include the total volume of all rooms specified in accordance with par. 6.4 when determining the volume enclosed by the envelope under test.

6.3.3 Correction of Air Flow Readings

Using the method described in Appendix B, correct each air flow reading for the indoor and outdoor temperatures, the ambient atmospheric pressure and the calibration temperature.

6.3.4 Determination of Correlation Coefficient

Applying the procedure described in Appendix C to the data collected, fit a curve of the form:

$$Q=C (dp)**n$$

where Q is in units of L/s

C is in units of  $\frac{L}{s.Pa**n}$

dp is in units of Pa

n is dimensionless

by the least squares method and calculate the correlation coefficient, n.

6.3.5 Calculation of Equivalent Leakage Area

6.3.5.1 Calculate the density of outside ambient air,  $\rho$ , using the following equation:

$$\rho = \frac{P}{R (T + 273)}$$

where  $\rho$  is in units of kg/m<sup>3</sup>

R = gas constant for air = 0.2872 J/g.k

P = ambient barometric pressure (kPa)

T = temperature of outside ambient air (C)

6.3.5.2 Knowing  $P$ , calculate the equivalent leakage area, ELA, using the following equation:

$$ELA = 1.57 \cdot (10^{**3}) \cdot P \cdot C \cdot 10^{**}(n-0.5)$$

$$ELA = 1.57 \cdot (10^{**3}) \cdot (P^{**0.5}) \cdot C \cdot 10^{**}(n-0.5) =$$

where ELA is in units of m<sup>2</sup>

$P$  is determined in accordance with par.6.3.5.1.

$C$  and  $n$  are determined in accordance with par.6.3.4.

## 7. TEST REPORT

7.1 The test report shall include the following information:

- a) The name and address of the company which conducted the test.
- b) The name of the testor.
- c) The address of the building under test.
- d) The date of test and the date of the report.
- e) The test conditions which include the outdoor temperature in C, the barometric pressure in kPa, the differential pressures measured in accordance with par 6.1.3 and comments on the wind speed, direction and variability.
- f) A description of the envelope under test if other than the building envelope.
- g) The area in m<sup>2</sup> of the envelope under test.
- h) The volume in m<sup>3</sup> enclosed by the envelope under test.
- i) The measured air flow rates in L/s, the corresponding pressure differences in Pa and the fan intake air temperatures in C.
- j) The corrected air flow rates in L/s at each pressure differential.
- k) Values for  $C$  and  $n$ .
- l) The determined correlation coefficient,  $n$ .
- m) The equivalent leakage area (ERA) in m<sup>2</sup>.
- n) When applicable, items i) to
- m) inclusive before and after sealing work.

o) Any deviation from the method prescribed.

7.2 It is recommended that the test report include the following:

a) If the building is of an unusual shape, a sketch of the building under test showing the locations of the pressure taps and the location of the fan.

b) A plot of the measured air flow rates versus the corresponding pressure differences on log-log paper.

### 7.3 Specimen Test Report

It is recommended that the test report follow the format given in Appendix D.

# THE RETROTEC DOOR FAN

The Retrotec Door Fan is a portable, accurate and very powerful fan depressurization system that heralds a new era for energy conservation technology and services. With the RDF you can:

- quickly and easily discover exactly where air is leaking into (and out of) buildings, and;
- accurately rate any building for air tightness.

## OPERATING PRINCIPLES

The Door Fan consists of a calibrated, variable speed fan mounted in an expanding panel system. The unit is temporarily installed in an exterior doorway. The fan is used to expel large amounts of air from the building, creating a negative pressure inside the building envelope. Air then leaks into the building at exaggerated rates, allowing for easy detection of air leakage sites. At the same time, the **pressure difference** across the building envelope can be compared to the **air flow** through the fan to obtain a measurement of "air tightness" for the building.

## UNEQUALLED CHARACTERISTICS

Two years of design and development work, and **extensive** field testing have produced a high quality product with your needs in mind.

### POWERFUL

The Retrotec Door Fan is the most powerful system commercially available — and for a good reason. Field tests have demonstrated that high air flow rates are essential for testing leaky buildings — precisely those buildings that can most benefit from air-tightening. Even large, tightly constructed buildings need high air flow rates to achieve the high negative pressures required for accurate testing.

### RUGGED AND PORTABLE

The RDF can be installed by one person in less than five minutes. The equipment can be transported in a hatchback. There are no messy fluids in the measurement system.

The RDF is powered directly from a standard household electrical outlet (there is a power connect on either side of the lower panel for adaptation to outside power source when necessary).

The RDF has been built to last with durable, high quality hardware and materials. The only maintenance required is occasional replacement of batteries (LCD read-out), paper (SHARP printer) and panel weatherstripping.

### REVERSIBLE

A simple flick of a toggle switch will reverse the system and permit the building to be pressurized. This option is especially useful when testing for air leakage sites in the attic or around the exterior of the building. The fan is also calibrated for air flow in reverse so that the building can be tested in both directions if desired. (The lower panel must be reversed if the bell-mouth nozzle is attached).

### VERSATILE

The RDF will fit approximately 95 per cent of existing door frames with **no** modifications or door removal. An even greater range is possible if the operator is prepared to use 2 x 4 spacers on exceptionally large door frames. The lower panels of the RDF can also be stacked, one on top of the other, to double the air flow when testing extremely large buildings.

## COMPUTERIZED

A built in computer takes all the error and pain out of the calculations, allowing for an almost instantaneous assessment of air tightness. Simply enter the temperature, area and volume of the building, and four or five pressure readings at different fan speeds, and the computer automatically prints out everything you will need to know, including:

- correlation of data,
- air flow at different pressures,
- air changes per hour at different pressures;
- equivalent leakage area;
- ratio of air flow to building surface area; and
- the logarithmic relationship between air flow and pressure difference.

The data correlation permits you to quickly determine if there is any bad data which might bias or disqualify the results. The air flows are all temperature corrected. The results can be printed in metric or imperial units. After completion of the test the computer and printer can be easily removed for other purposes if desired.

## ACCURATE

The Retrotec Door Fan calibration facility was developed with assistance from the National Research Council of Canada and employs an air-tight chamber, sharp edged orifice plates, and a pitot traverse flow measuring system. Each RDF has been accurately calibrated for air flow before leaving the shop. Analogue pressure gauges are also recalibrated for accuracy.

The Door Fan system incorporates many features intended to facilitate accurate, repeatable measurements. To ensure consistent high air flow measurements the system employs venturi rings on both sides of the fan with an aluminum honeycomb flow straightener mounted up stream of the blades, and a pressure averaging system is used to reduce inaccuracies due to wind gusting. Accurate measurement of the low air flows needed to test air tight buildings is obtained by attaching the bell mouth nozzle.

The Door Fan system currently meets all requirements of the CGSB and ASTM standards for air tightness testing of new buildings. The system can also produce consistent results when testing older, leaky buildings. Your test reports will avoid conflicting data which might confuse clients, dishearten tradesmen, or damage your reputation for competence and professionalism.

## APPLICATIONS

The RDF has been intentionally designed to meet a range of applications. It is an all-purpose system. The most common applications are described below.

### AIR LEAKAGE DETECTION

The fan induced negative pressure causes air to rush in through every crack and hole in the building envelope. The operator can detect these leaks by using an inexpensive smoke pencil to create puffs of cool smoke next to any suspicious-looking areas. Even the most tiny air leaks become visible geysers of smoke. The effect is most impressive. Building owners are easily convinced of the value of air tightening work when they can actually "see" the magnitude of the problem.

Alternatively the operator can use an infra-red scanner to locate cold air leaking into the building. Infrared equipment works far better when used in conjunction with the Door Fan since all air leakage will be "cold" air instead of a hopeless confusion of infiltration and exfiltration.

Once air leaks have been detected they can be quickly recorded on a master chart for future reference. Efforts to tighten the building can then be directed at the most extreme leaks or at the most cost-effective areas.

### QUALITY CONTROL FOR RETROFIT WORK

The RDF can be used as a quality control device for anyone involved in weatherizing, re-insulating or renovating buildings. A comparison of air tightness tests performed **before** and **after** the job provides an accurate and objective evaluation of any airtightening work.

The RDF can be an especially effective marketing tool. Retrofit contractors can specify a minimum reduction in air leakage rates; and builders can promise energy efficient buildings that are "certified" airtight. Eventually the results of airtightness tests will become as important as "R" values in defining the energy efficiency and comfort of a building, and even more important as a measurement of the building's integrity and durability.

National standards for air tightness in buildings have recently been established in both Canada and the United States.\* These standards rely on door fans to test for air tightness. Eventually such standards will be incorporated into national and local building codes for new houses. In Sweden such a regulation has been in place since 1976 with considerable success (new homes in Sweden are approximately three times as tight as Canadian new homes). Even now the more progressive home builders are using the RDF to evaluate their construction techniques and to provide their clients with certificates of air tight construction.

\*Canadian General Standards Board 149 GP 10

## ENERGY SURVEYS AND BUILDING DIAGNOSIS

The RDF can definitely improve the accuracy and usefulness of any recommendations for energy conservation in buildings. In fact, without the Door Fan an energy consultant will have only the vaguest ideas about the real distribution and magnitude of air leakage.

The RDF was originally developed as a part of a building science kit for use by energy consultants. It is an excellent research and diagnostic tool since air leakage is often a key factor — not just in energy conservation programs — but in solving a host of problems related to moisture depositions, structural degradation, occupant discomfort and ventilation control.

## SPECIFICATIONS

Air Flow .....	Maximum 2.75 m <sup>3</sup> sec at 60 Pa (5800 cfm at .25" H <sub>2</sub> O)
Power Requirements .....	115 VAC 9 VDC (battery for digital tach)
Minimum Door Frame Dimensions .....	755 mm x 1981 mm (29.75" x 78")
Maximum Door Frame Dimensions .....	965 mm x 2184 mm (38" x 86")
Weight .....	lower panel 29.5 kg. (65 lbs) upper panel 11.3 kg. (25 lbs) control box 5.5 kg. (12 lbs)
Building Size Limitations .....	Approximately 600 m <sup>2</sup> floor area (6000 ft <sup>2</sup> ) in very leaky buildings approximately 6000 m <sup>2</sup> (60,000 ft <sup>2</sup> ) in new airtight construction.
Colour .....	black and dark bronze
Reversibility .....	toggle switch
Expansion System .....	spring loaded locking cams
Panel Finish .....	anodized aluminum
Computer Printer .....	SHARP PCI2II with CE122 (can be removed for other uses)

The RETROTEC DOOR FAN is warranted by RETROTEC Energy Innovations Ltd. to the original user against defects in workmanship or materials under normal use for 120 days after purchase. Any part which is determined to be defective in material or workmanship and returned to RETROTEC with prior authorization, shipping costs prepaid, will be repaired or replaced at RETROTEC's option. Various subcomponents (i.e. SHARP computer and printer) have longer warranty periods. A full description of the limited warranty is included with the Door Fan.

not shown in this drawing:

## HOUSEHOLDER REPORT

A convenient way of describing the 'leakiness' of houses is to imagine how big a hole your house would have if you could gather all the leaks into one place. This is referred to as an EQUIVALENT LEAKAGE AREA or ELA. With our specialized equipment we have determined that the ELA in your house is .12 M<sup>2</sup> (at a pressure difference of 10 pascals). This is compared graphically to other houses in the figure below:

### Leak Location Check List

A check list of leakage areas found in the test is listed below on a room basis. One check (✓) indicates a bad leak while two checks (✓✓) indicates a real problem area.

<b>Living Area</b> Switch Covers <input type="checkbox"/> Outlet Covers <input checked="" type="checkbox"/> Window Pane <input type="checkbox"/> Window Frame <input checked="" type="checkbox"/> Window Moldings <input checked="" type="checkbox"/> Around T.V. ## HOUSEHOLDER REPORT

A convenient way of describing the 'leakiness' of houses is to imagine how big a hole your house would have if you could gather all the leaks into one place. This is referred to as an EQUIVALENT LEAKAGE AREA or ELA. With our specialized equipment we have determined that the ELA in your house is .14 M<sup>2</sup> (at a pressure difference of 10 pascals). This is compared graphically to other houses in the figure below:

### Leak Location Check List

A check list of leakage areas found in the test is listed below on a room by room basis. One check (✓) indicates a bad leak while two checks (✓✓) indicates a real problem area.

<b>Living Area</b> Switch Covers <input type="checkbox"/> Outlet Covers <input checked="" type="checkbox"/> Window Pane <input type="checkbox"/> Window Frame <input type="checkbox"/> Window Moldings <input type="checkbox"/> Around T.V. ## HOUSEHOLDER REPORT

A convenient way of describing the 'leakiness' of houses is to imagine how big a hole your house would have if you could gather all the leaks into one place. This is referred to as an EQUIVALENT LEAKAGE AREA or ELA. With our specialized equipment we have determined that the ELA in your house is .10 M<sup>2</sup> (at a pressure difference of 10 pascals). This is compared graphically to other houses in the figure below:

### Leak Location Check List

A check list of leakage areas found in the test is listed below on a room by room basis. One check (✓) indicates a bad leak while two checks (✓✓) indicates a real problem area.

#### Living Area

- Switch Covers
- Outlet Covers
- Window Pane
- Window Frame
- Window Moldings
- Around T.V. Cable
- Baseboards
- Ceiling Cracks
- Wall Cracks
- Ceiling Fixtures
- Dropped Ceiling
- Fireplace Damper
- Fireplace/Wall Joint
- OTHER

#### Kitchen

- Switch Covers
- Outlet Covers
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
- Wall Cracks
- Ceiling Cracks
- Ceiling Fixtures
- Plumbing Holes
- Exhaust Fans
- OTHER

#### Family Area

- Switch Covers
- Outlet Covers
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
- Wall Cracks
- Ceiling Cracks
- Ceiling Fixtures
- Around T.V. Cable
- Fireplace Damper
- Fireplace Wall/ Joint
- OTHER
- Master Bedroom Windows

#### Dining Area

- Switch Covers
- Outlet Covers
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
- Wall Cracks
- Ceiling Cracks
- Ceiling Fixtures
- OTHER

#### Bedroom

- Switch Covers
- Outlet Covers
- Ceiling Fixtures
- Baseboards
- Window Panes
- Window Frame
- Window Moldings
- Ceiling Cracks
- OTHER

#### Bedroom W

- Switch Covers
- Outlet Covers
- Ceiling Fixtures
- Baseboards
- Window Panes
- Window Frame
- Window Moldings
- Ceiling Cracks
- OTHER

#### Bedroom MASTER

- Switch Covers
- Outlet Covers
- Ceiling Fixtures
- Baseboards
- Window Panes
- Window Frame
- Window Moldings
- Ceiling Cracks
- OTHER

#### Bedroom E

- Switch Covers
- Outlet Covers
- Ceiling Fixtures
- Baseboards
- Window Panes
- Window Frame
- Window Moldings
- Ceiling Cracks
- OTHER

#### Bathroom MASTER

- Bathtub/Shower
- Medicine Cabinet
- Ceiling Vent
- Switch Cover
- Outlet Cover
- Plumbing Penetrations
- Baseboards
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
- OTHER

#### Bathroom HALL

- Bathtub/Shower
- Medicine Cabinet
- Ceiling Vent
- Switch Cover
- Outlet Cover
- Plumbing Penetrations
- Baseboards
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
- OTHER

#### Laundry Area

- Switch Covers
- Outlet Covers
- Ceiling Fixtures
- Baseboards
- Wall Cracks
- Ceiling Cracks
- Window Panes
- Window Frames
- Window Molding
- Plumbing Penetrations
- Dryer Venthole
- OTHER

#### Attic Living Area

- Switch Covers
- Outlet Covers
- Chimney Cavity
- Around Chimney
- Heating Ducts
- Wiring Penetrations
- Exhaust Ventilation
- Window Panes
- Window Trim
- Window Moldings
- Baseboards
- Ceiling Fixtures
- Drawers into Knee Wall
- Top Plate
- OTHER
- Attic Hatch

#### Basement

- Plumbing Vent to Roof
- Around Chimney
- Oil/Gas Wall Holes
- Basement/Crawl Space Joint
- Combustion Air Inlet
- Window Panes
- Window Frame
- Window Moldings
- Baseboards
- Ceiling Cracks
- Wall Cracks
- Ceiling Fixtures
- Wiring Hole to Upstairs
- Wiring Holes to Outside
- Wall/Sill Joint
- Wall/Sub Floor Joint
- Wall/Joist Joint
- OTHER

#### Other

- Stair Risers
- Floor Level Changes
- Addition Attachment
- Hall Window

#### Attic

- Attic Hatch
- Top Plate
- Junction Box
- Wiring Penetrations
- Chimney Cavity
- Exterior Walls
- Plumbing Stack
- OTHER

#### Exterior Door

- Threshold
- Casing
- Frame
- Moldings
- Pane
- Mail Slot
- Panels
- OTHER

#### Exterior Door FRONT

- Threshold
- Casing MAJOR SIDE
- Frame
- Moldings
- Pane
- Mail Slot Beil
- Panels
- OTHER
- Switch by Front
- Outlet by Sill

## HOUSEHOLDER REPORT

A convenient way of describing the 'leakiness' of houses is to imagine how big a hole your house would have if you could gather all the leaks into one place. This is referred to as an EQUIVALENT LEAKAGE AREA or ELA. With our specialized equipment we have determined that the ELA in your house is .14 M<sup>2</sup> (at a pressure difference of 10 pascals). This is compared graphically to other houses in the figure below:

### Leak Location Check List

A check list of leakage areas found in the test is listed below on a room basis. One check (✓) indicates a bad leak while two checks (✓✓) indicates a real problem area.

## HOUSEHOLDER REPORT

A convenient way of describing the 'leakiness' of houses is to imagine how big a hole your house would have if you could gather all the leaks into one place. This is referred to as an EQUIVALENT LEAKAGE AREA or ELA. With our specialized equipment we have determined that the ELA in your house is .19 M<sup>2</sup> (at a pressure difference of 10 pascals). This is compared graphically to other houses in the figure below:

### Leak Location Check List

A check list of leakage areas found in the test is listed below on a room basis. One check (✓) indicates a bad leak while two checks (✓✓) indicates a real problem area.

#### Living Area

- Switch Covers
- Outlet Covers
- Window Pane
- Window Frame
- Window Moldings
- Around T.V. Cable
- Baseboards
- Ceiling Cracks
- Wall Cracks
- Ceiling Fixtures
- Dropped Ceiling
- Fireplace Damper
- Fireplace/Wall Joint
- OTHER \_\_\_\_\_

#### Kitchen

- Switch Covers
- Outlet Covers
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
- Wall Cracks
- Ceiling Cracks
- Ceiling Fixtures
- Plumbing Holes
- Exhaust Fans
- OTHER \_\_\_\_\_

#### Family Area

- Switch Covers
- Outlet Covers
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
- Wall Cracks
- Ceiling Cracks
- Ceiling Fixtures
- Around T.V. Cable
- Fireplace Damper
- Fireplace Wall/ Joint
- OTHER \_\_\_\_\_

#### Dining Area

- Switch Covers
- Outlet Covers
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
- Wall Cracks
- Ceiling Cracks
- Ceiling Fixtures
- OTHER \_\_\_\_\_

#### Bedroom 2

- Switch Covers
- Outlet Covers
- Ceiling Fixtures
- Baseboards
- Window Pane
- Window Frame
- Window Moldings
- Ceiling Cracks
- OTHER \_\_\_\_\_

#### Bedroom 4

- Switch Covers
- Outlet Covers
- Ceiling Fixtures
- Baseboards
- Window Panes
- Window Frame
- Window Moldings
- Ceiling Cracks
- OTHER \_\_\_\_\_

#### Bedroom 3

- Switch Covers
- Outlet Covers
- Ceiling Fixtures
- Baseboards
- Window Panes
- Window Frame
- Window Moldings
- Ceiling Cracks
- OTHER \_\_\_\_\_

#### Bedroom MASTER

- Switch Covers
- Outlet Covers
- Ceiling Fixtures
- Baseboards
- Window Panes
- Window Frame
- Window Moldings
- Ceiling Cracks
- OTHER \_\_\_\_\_

#### Bathroom MASTER

- Bathub/Shower
- Medicine Cabinet
- Ceiling Vent
- Switch Cover
- Outlet Cover
- Plumbing Penetrations
- Baseboards
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
- OTHER \_\_\_\_\_

#### Bathroom UP

- Bathub/Shower
- Medicine Cabinet
- Ceiling Vent
- Switch Cover
- Outlet Cover
- Plumbing Penetrations
- Baseboards
- Window Pane
- Window Frame
- Window Moldings
- Baseboards
